ANNUAL FAIR OF THE PLANTERS' CLUB OF HANCOCK.

SPARTA, November 1 and 2, 1844.

Mr. Editor:—The Executive Committee of the Planters' Club of Hancock, transmit to you for publication, the following synopsis of the proceedings on the days of the Annual Fair:

The Club convened at the Female Academy, on Friday the 1st, when many citizens from this and the adjoining counties had met to witness the examination of the various kinds of domestic fabrics and stock, which were examined by the several committees; and on Saturday, the committees reported and premiums and honors awarded; and an address, both interesting and instructing, was delivered by James Thomas, Esq., to a large collection of ladies and gentlemen.

The premiums and honors awarded, were:—

To Mrs. Sam'l. A. Pardu, for 8 yds. best homespun, for gentlemen's wear $3.00
Mrs. L. S. Bass, for 2 yds. do 2.00
Mrs. A. C. Whitehead, for 3 yds. do 1st honor.
Mrs. Jones, of Warren co., for 4 yds do 2d "
Miss M. A. Battle, for 5 yds. do 3d "
[Miss B. has made 95 yds., same kind of goods, since 1st July last.]
A lady of Warren co., for 8 yds. homespun, ladies' wear, $1.00
" for a beautiful silk and satin bed quilt, (exhibited by T. Neal, Esq.) 3.00
Miss Susan Jones, of Warren co., for 2d best do 2.00
Mrs. Mansfield, for a pair black silk hose, (domestic manufacture,) 1.00
Miss C. F. Haynes, for an open work linen cambric handkerchief, 1.00
Mrs. O. H. Lanier, for a lady's knit collar, 1.00
Mrs Richards, for a beautiful bead purse, 1.00
Miss Garrett, for a knit cap, 50
Miss Mary Coleman, for a pair worsted mitts, 50
Miss A. L. Battle, " " silk mitts, 50
Mrs. O. H. Lanier, for 8 yds. handsome knit edging, 50
Miss C. Smith, for 2 imitation coral baskets, 50
Mrs. Martha Anne Lewis, for the best acre of corn (96¼ bushels)—a silver cup, 10.00
Thomas C. Grimes, for the 2d best do (64 7-10 bushels) 5 00
Edmond M. Pendleton, for the 3d best acre of corn, (52⅝ bushels,) $3.00
Benj. T. Harris, for the 4th best do (48⅝ bushels,) honor.
*R. S. Hardwick, for the 5th best do (14 bushels,) honor.
William Terrell, for the best acre of wheat, 25⅜ bushels,) $10— in a silver cup.
E. M. Pendleton, for the 2d best do (19 bushels,) $5.00
Thos. C. Grimes, for the 3d do (16 bushels) 3.00
James P. Knowles, for the best boar, 3.00

There were some very fine stock hogs exhibited by Harwick, but not for premiums.

Thomas C. Grimes, for 2 Durham bulls, and one Durham cow, $10.00
William Terrell, for a native stock milch cow, 2 00
Do do do honor.
Benj. T. Harris, for a milch cow, 3.00
Thomas Neal, for his bay horse, Wonder, 5 years old, 5.00
James Mitchell, for his black horse, 5 years old, 3 00
Sam'l. A. Pardu, for his bay horse, De Witt, 4 years old, 3.00
James B. Edwards, for his bay filly, 4 years old, 3.00
R. S. Hardwick, for his bay filly, 4 years old, 2.00
Thomas C. Grimes, for his filly, 3 years old, 3.00
James McCason, for his sorrel filly, 3 years old, 2.00
John F. Brooke, for his filly, 3 years old, honor.
L. S. Brooking, for his bay filly, May Blossom, 2 years old, 3.00
John F. Brooke, for his colt, 1 year old, 3.00
F. D. Gonder, for his filly, do do 2.00
Thomas Neal, for his brood mare, Lucinda and colt, 5.00
do for his do Spangle and colt, 2.00
Richard P. Sassnett, for best acre of cotton, (2037 lbs.)—$10, in a silver cup.
Benj. T. Harris, for the 2d best do (1728½ lbs.) 5.00
R. S. Hardwick, for the 3d best do (1600 lbs.) 3.00

The officers for the ensuing year, are

Myles G. Harris, President.
Thomas Whaley, 1st Vice President.
Charles R. Knowles, 2d " "
J. P. Whitehead, 3d " "
Tuttle H. Audas, Secretary.
Nathan C. Sayre, Corresponding Secretary.

Resolved, That the proceedings of the Fair be published in the Southern Cultivator and Milledgeville papers.

TUTTLE H. AUDAS, Secretary.

The great political excitement in the country, at the time of the Fair, did not add anything to the great cause of agriculture, though our Fair was very respectably attended; and as the excitement has now ceased, our people begin to talk on the subject of agriculture more than ever, and seem determined to direct some of their energy and force to something that will be more profitable than cotton, by dividing their labor. And as there will not be a President to elect next November, we expect our Fair to be by far the most brilliant that we have ever had. Our prospects are now brighter than at any time heretofore. The cause of agriculture must and will prevail. Yours, with respect,

T. H. A.

*See the mode of culture by Hardwick, to be published hereafter.—*Secretary.*

LIST OF PREMIUMS OFFERED FOR THE ANNUAL FAIR IN 1845.

The Annual Fair of the Planters' Club of Hancock, will take place at Sparta, on Friday and Saturday before the first Monday in November, 1845, when the following premiums and honors will be awarded:

For the best acre of upland corn, a silver cup—value, $10.00
" 2d do do 5.00
" 3d do do 3.00
" 4th and 5th do do honors.
For the best low ground corn, without manure, $5.00
" 2d do do 3.00
" 3d do do 2.00
" 4th and 5th do honors.
For the best acre of wheat on upland, a silver cup—value, $10.00
" 2d do do 5 00
" 3d do do 3.00
" 4th and 5th do honors.
For the best cotton on upland, a silver cup—value, $10.00
" 2d do do 5.00
" 3d do do 3.00
" 4th and 5th do honors.
For the best oats on upland, $3.00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.
For the best acre of potatoes, $3 00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.
For the best acre of turnips, $3.00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.

By a rule of the Club, competitors for premiums on crops will be required to give the *modus operandi* of culture, the quantity and quality of manure applied, and evidence that the land reported on contains only one acre or acres, and the crop accurately measured.

For the best jack, a premium of $5.00
" 2d do do 3.00
For the best Georgia raised mule, 3.00
" 2d do do do 2.00
For the best mule colt, 3.00
" 2d do do 2.00
For the best stallion, 4 years old or upwards 5.00
" 2d do do do 3.00
" 3d, 4th and 5th do do honors.
For the best 3 year old colt or filly, $3 00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.
For the best 2 year old colt or filly, $2.00
" 2d do do 1.00
" 3d, 4th and 5th do do honors.
For the best brood mare, with or without a colt, $5.00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.
For the best bull, 3.00
" 2d do do 2.00
" 3d, 4th and 5th do do honors.
For the best 2 year old bull, $2.00
" 2d do do 1.00
" 3d, 4th and 5th do do honors.
For the best cow producing the largest quantity of milk without regard to blood, $5.00
" 2d do do do 3.00
" 3d do do do 1.00
" 4th and 5th do do honors.
For the best cow, having regard to blood, $5.00
" 2d do do 3.00
" 3d do do 2 00
" 4th and 5th do do honors.
For the best 2 year old heifer, $2.00
" 2d do do 1.00
" 3d, 4th and 5th do do honors.
For the best ram, $2.00
" 2d do do 1.00
" 3d, 4th and 5th do honors.
For the best Ewe, $2.00
" 2d do do 1.00
" 3d, 4th and 5th do honors.
For the best boar, $3.00
" 2d do do 2.00
" 3d, 4th and 5th do honors.
For the best sow, $3.00
" 2d do do 2.00
" 3d, 4th and 5th do, honors
For the heaviest fat hog agreeable to age, $5.00

" 2d do do do 3.00
" 3d do do do 2.00
" 4th and 5th do do do honors.
For the heaviest pig, agreeable to age, from 6 to 12 months, $5.00
" 2d do do 3.00
" 3d do do 2 00
" 4th and 5th do do honors.
For the best piece of 8 yards homespun, gentlemen's wear, $3.00
" 2d do do 2 00
" 3d do do 1 00
" 4th and 5th do do honors.
For the best 10 yards do for ladies' wear, $3 00
" 2d do do 2 00
" 3d 4th and 5th do do honors.
For the best counterpane, $3.00
" 2d do do 2.00
" 3d 4th and 5th do honors.
For the best piece of 10 yds. domestic silk $5.00
" 2d do do 3 00
" 3d do do 2.00
" 4th and 5th do do honors.
For the best article of negro clothing, $3.00
" 2d do do 2.00
" 3d 4th and 5th do do honors.
For the best negro blanketing, $2.00
" 2d do do 1.00
" 3d 4th and 5th do do honors.

The Club have set apart $20, to be awarded by their committees to articles manufactured by ladies and not embraced in their list of premiums, such as caps, capes collars, stockings, gloves purses, and such other articles as the taste and fancy of ladies may induce them to present.

Resolved, That no animal, nor article, shall for the future be permitted to take a premium of the same class or number the second time, but may be exhibited and take in any class or number above the rank that they were placed at the previous fair—and that this resolution be published with the next premium list.

The Club being impressed with the great importance to the country, of raisng their own pork and wool, will in addition to the foregoing premiums offer for the greatest amount of pork, not less than 300 lbs net, raised for each member of family, including whites and blacks, a silver cup—value $10.00
For the 2d highest amount in pounds, 5.00
" 3d do do 3 00
" 4th and 5th do (none to be less than 300 lbs,) honors.
For the greatest number of pounds of wool raised (clean) to the number in family, including whites and blacks, a silver cup, $10.00
" 2d do do do 5.00
" 3d do do do 3.00
" 4th and 5th do do do honors.

TUTTLE H. AUDAS, Secretary.

From the South Carolina Temperance Advocate.

PROCEEDINGS OF THE STATE AGRICULTURAL SOCIETY.

COLUMBIA, November 25, 1844.

The State Agricultural Society met, agreeably to notice, and the delegates having enrolled themselves, the Society was organized by the President, and proceeded to business.

The alteration of the Constitution, requiring the formation of an Executive Committee, composed of the officers of the Society and three members, was called to the attention of the Society; on motion, the President appointed Hon. J. B. O'Neall, Hon. F. W. Pickens and J. W. Roper, as the Committee, with the officers.

The following documents were presented to the Society and respectively referred to the Executive Committee and the Committees appropriated for each:

The Black Oak Agricultural Society forwarded a Report of one of their Committees on Manures.

A Report of the Officers and members of the Cambridge Agricultural Society.

The Wateree Agricultural Society sent a report on Potatoes—also one on Corn—to be referred to the Committee of awards on Potatoes and Corn.

From the Newberry Agricultural Society, praying that the next meeting of the State Agricultural Society be held in the village of Newberry.

A document containing marling facts and estimates, from Edmund Ruffin, late Agricultural Surveyor of South Carolina.

The entire proceedings of the New York State Agricultural Society, was forwarded through Col. A. Summer, together with sundry documents relative to the diffusion of agricultural knowledge.

Mr. McCarthy moved that the thanks of this Society be tendered to the officers of the State Agricultural Society of New York, for the volumes and documents relative to Agricultural subjects which they have presented to this Society, and that the Secretary be hereby instructed to present copies of *similar* publications and documents of this Society to the officers of the aforesaid State Agricultural Society of New York.

A communication was presented from F. D. Quash, Corresponding Secretary of the South Carolina Society, asking the aid of the State Agricultural Society, in petitioning the Legislature for the continuance of the Agricultural Survey of the State.

Also, a letter from Edmund Ruffin, in reply to one from the President, returning the thanks of this Society to him for his services as Agricultural Surveyor of the State.

Also, a letter from R. W. Aliston, concerning the account of an experiment in the culture of *Rice*, and the production of an acre.

Also, one from A. H. Seabrook, one of the competitors for the premium for the greatest amount of Sea Island Cotton, having reference to quality and valuation.

Also, one from W. Wright, of York, a competitor from York for the premium for the greatest amount of wheat per acre.

Also, one from D. J. Mesuain, of York, for the premium for the greatest amount of corn per acre.

The Hon. J. B. O'Neall presented the following, as an amendment to one of similar purport offered by Mr. Roper, viz:

Resolved, That an application be made by the President to the Legislature, requesting them to make an appropriation equal in amount to the sum contributed by the members and delegates of the State Agricultural Society, to be, by the State Agricultural Society, expended in premiums at its semi-annual and annual meetings, and for such other Agricultural purposes as they may think proper.

This motion was discussed by Col. Edwards, Hon. J. B. O'Neall and Mr. McCarthy, and agreed to.

Dr. Gibbes commnnicated that the Committee appointed at the last meeting of the Society, for the purpose of memorializing the Legislature for the continuance of the Agricultural and Geological Survey, respectfully Report:—That they have discharged the duty, and that the Memorial is prepared and ready to be presented to the Legislature.

The President called the attention of the Society to a communication addressed to the Hon. Geo. McDuffie, W. McWillie and W. B. Seabrook, from Col. F. W. Davie.

Hon. J. B. O'Neall moved that a Committee of five be appointed, with the President as chairman, to report upon this communication at the semi-annual meeting of this Society.

The following gentlemen were in consonance appointed: Geo. McDuffie, W. McWillie, J. B. O'Neall and Wm. J. Alston.

The Society adjourned till 7 o'clock on Tuesday evening.

TUESDAY EVENING, Nov. 26.

The Society convened as ordered, and the proceedings were read by the Secretary.

The President announced the following Committees:

For the best cultivated Farm.—J. B. O'Neall, Newberry; L. A. Beckham, Chester; E. G. Palmer, Fairfield; Wm. Cain, Black Oak; J. Lartigue, St. Peter's.

Short Staple Cotton.—John H. Means, Fairfield; Joel Smith, Abbeville; Thos. H. Pope, Newberry; Wm. J. Taylor, Kershaw.

Long Staple Cotton.—John Rivers, St. Andrews; J. Fickling, St. Lukes; Dr. P. Palmer, St. John's Berkley; Wm. M. Murray, St. John's Colleton.

Rice—R. W. Roper, St. Philip and St. Michael; P. W. Frazer, Prince George; John Harlston, St. John's Berkley.

Corn and other Grain.—R. F. W. Alston, Prince George; Edward Harleston, Anderson; P. S. Brooks, Edgefield; W. McWillie, Kershaw; J. M. Felder Orangeburg; A. Hibben, Christ Church.

Potatoes.—Dr. P. Palmer, St. John's Berkley; —— Maxwell, Anderson; A. Summer, Newberry; N. L. Griffin, Edgefield; Paul Grimball, St. John's Colleton; B. B. Porter.

Silk.—William Summer, Newberry; Samuel Earle, Greenville; W. G. Simms, Barnwell; W. Giles, York; E. P. Smith, Spartanburg.

Domestic Fabrics.—Dr. R. W. Gibbes, Columbia; B. F. Perry, Greenville; W. J. Alston, Fairfield; F. W. Pickens, Edgefield; Dr. Guillaird, Anderson.

Marl.—Wm. M. Murry, Dr. R. W. Gibbes, R. W. Roper.

The communications were then respectively referred to the Committees, together with the certificates or premiums.

Mr. McCarthy moved the following:

Whereas the opinion has become impressed upon the public mind, that all useful advancement in Agricultural improvement and in the arts of rural economy, mainly depend upon the collection of the numerous facts which are furnished by observation and experiment, and by the discoveries of practical science; and inasmuch as many of the States of this Union are in advance of our own, in both experimental and scientific knowledge, in all the branches of industrial labor, through the instrumentality of local and State Societies, aided, in many instances, by the encouragement which is afforded by legislative assistance:

And, whereas, it is expedient that this Society should avail itself of all the lights and information which have been obtained elsewhere, by means either of individual or associated experiment, or by scientific discovery; and an object of special interest at this time is to ascertain, from indubitable sources, what has been the experience of those States in reference to the benefits resulting from legislative assistance, in which appropriations in aid of Agriculture have been made:

Be it therefore Resolved, That a Committee of five members be hereby appointed, of whom the Corresponding Secretary shall be chairman, who shall be charged with the duty of instituting a correspondence with such of the States as they shall think proper, by communications, addressed to the Governors, Secretaries of State, or to the Presidents of local or State Societies, for the purpose of acquiring such information as will enable them to present to this Society at its next meeting, a full and authentic report upon the following points:

1. What assistance has been offered by legislation in the States to the advancement of Agriculture and the arts of Husbandry.

2. In what manner and under what regulations and restrictions has this assistance been rendered.

3. What benefits to Agriculture have been derived from legislative appropriations, and in what way has their application proved most available.

4. Has the apparent and practical benefit derived from the fostering aid of government, afforded sufficient encouragement to induce the States to continue its appropriations for a succession of years.

5. Have the States, or any of them, caused Agricultural or Geological Surveys, and Reports to be made, and to what effect? And what

benefits have resulted to Agriculture from these services.

These resolutions were sustained by the mover and carried. The following is the Committee under the above resolution :—Dr. R. W. Gibbes, Ed. G. Palmer, Whitfield Brooks, W. Gilmore Simms, A. H. Boykin, R. W. Roper.

Mr. A. G. Summer moved that a sufficient portion of the Hall of this House be appropriated for the accommodation of the Ladies on Thursday evening, at the Anniversary of this Society, which was agreed to.

The Secretary moved that a committee be appointed by the President to inquire into the means of this Society, and report at its next meeting—and the following gentlemen were appointed: Wm. J. Alston, J. Lartigue, I. DuBose.

The Society adjourned till Thursday evening, 7 o'clock.

—

THURSDAY EVENING, 7 o'clock.

The Society convened as appointed, and being organized, the Secretary read the proceedings of the last meeting.

The reports from the several Chairmen were now offered, as follows :

The Committee to whom it was referred to award the premium for the best conducted farm, beg leave to report: That the only claim presented to them was that of Whitfield Brooks, Esq. On examining the description given of it by the officers and members of the Cambridge Society, your Committee are of opinion that Col. Brooks has not only most fairly and fully entitled himself to the premium, but also, that the description of his plantation should be published, as an example worthy of imitation.

JOHN BELTON O'NEALL, Chairman.

—

The Committee on Potatoes respectfully report: That but one individual came forward to compete for the premium on this crop, Mr. R. Cameron, of the Wateree Agricultural Society, who presented a certificate of the crop raised by him, from the Wateree Agricultural Society. His crop was four hundred and thirty-six and three-eighths bushels per acre. Your Committee accordingly recommend that he receive the premium offered by this Society.

Your Committee would particularly notice the fine specimens exhibited to the State Agricultural Society, by Col. R. F. W. Allston, and regret that he did not furnish the Society with an estimate of his crop.

PETER P. PALMER, Chairman.

—

The Committee on Corn and other Grain beg leave to report: That for the premium on Corn there were two competitors; one showing a production of 86 bushels and 19½ quarts, from one acre, duly attested by the Secretary of the Agricultural Society in Kershaw District—the other showing a production of 105 bushels and 18 quarts from one acre, but unaccompanied by any certificate of any officer of the Agricultural Society of York District. Under the circumstances your Committee are unable to award any premium. They take occasion to suggest that the Society, in future, should require of applicants for the premiums of this Society, to produce a statement of the culture used by the proprietor or overseer—a statement certified by the President or Secretary of the local Agricultural Society, of the measured quantity of land, (45,000 square feet to the acre,) also of the measured *quantity* and weight per bushel of the grain.

There was but one applicant for the premium on Wheat. The Committee do not regard the production as very great, but were pleased with the evidence afforded of the enterprize and perseverance of the farmer in manuring his land and cultivating his grain. His treatment is given during three years, and the whole is duly certified.

The Committee recommend that the premium for Wheat be awarded to Col. Wm. Wright of York District.

Your Committee further recommend, that the very interesting letter of Gen'l. Jamieson, on Millet, to the Society, be published, with the proceedings of this meeting.

R. F. W. ALLSTON, Chairman.

—

The Committee on Rice have received but one communication upon its mode of culture, and from the facts and results detailed in the Report, consider the means employed in the culture, scientific and useful. The result of the quantity of land planted and tended, according to the statement rendered, was at the rate of seventy-eight and three-quarter bushels per acre. This, although by no means an unprecedented quantity, is yet very large, and from the quality of the Rice, entitles the grower, Mr. R. F. W. Allston, to the premium. The suggestions of Mr. Allston, as to the propriety of offering a premium for the discovery of the cause of the rust and chalk in Rice, is left by the Committee to the wisdom of the Society to determine. All the facts contained in the documents upon which this Report is predicated, are so fully detailed, that your Committee deem it unnecessary to enlarge further upon the subject.

All which is respectfully submitted.

R. W. ROPER, Chairman.

—

The Committee on Long Cotton regret there was no competitor for the premium. One sample only has been submitted to their inspection by Mr. Archibald Seabrook, of Edisto Island, of very superior quality, both in length and fineness of staple, grown from selected seed. It appeared that Mr. Seabrook, raised 5440 lbs. of cotton in the seed, to eight acres, which was designed for this premium. Upon this land, 160 piled single horse cart loads of marsh were put in August, 1843, immediately after being cut and partly listed in, merely to prevent the depredations of cattle, and, (as he expresses himself,) "to allow the marsh to rot on the ground intended for cultivation." In this way the saline and other ingredients not evaporable were preserved. By exposure, too, for several months, to the combined action of air, light and moisture, the process of decomposition in the spring is regular, and the matter becomes food for the plants early in the season. It requires of this quality of cotton 1500 lbs. in the seed, to make 300 lbs. of clear ginned cotton. At this rate, if the cotton commands the lowest prices at which it has been valued by two disinterested factors in Charleston, it will realize in money $95 to the acre. Your Committee therefore recommend the premium to be awarded to Mr. Archibald H. Seabrook, of Edisto Island.

JNO. RIVERS, Chairman.

—

The Committee on Silk respectfully report that they examined the specimens presented to them, and would recommend that the premium be awarded to Mrs. Mary W. Dantzler, of Spartanburg District, for the white Silk Vesting, manufactured and presented to the inspection of the Society. Her lot consisted of Vesting Cloth, and a fine net Shawl, of single silk, beautifully made.

They would notice favorably a net shawl from Miss Cassandra Poole, of Spartanburg, of equal beauty with the one mentioned above, which was the work of her own hands, from the feeding of the worms, to the netting of the shawl. Also, from Miss Harriet D. Davis, of Abbeville, a net Shawl of sewing silk, which displayed great care in its manufacture—also a silk pocket. From Miss S. M. Davis a pair of Silk Hose; and from Mrs. Sam'l. Reid, a pair of Silk half Hose. From Mrs. P. H. Baskin, of Abbeville, a beautiful plaid Shawl, of wove silk. From Wm. H. Villard, of Aiken, forty net Shawls of various patterns, the work of his daughter, Miss P. H. Villard. From Mrs. and Miss Crosby, of Lowndesville, Abbeville District, a few specimens of Silk Cloth, mixed with wool, and from Mrs. Reid, a piece of Cloth of the same kind.

Your Committee are sorry that the limited means of the Society prevent them from bestowing premiums of a secondary value to others of those who have favored the Society with their beautiful articles of domestic industry and delicate handiwork.

WM. SUMMER, Chairman.

—

The Committee on Domestic Fabrics report that they have examined carefully the specimens submitted to them, and recommend for premiums the following articles: A specimen of Cotton Bagging, of manufactured cotton, from the Pendleton Factory, which the Committee considers the best and most substantial article of the kind ever seen by them—a specimen of Worsted Cloth, manufactured by Mrs. Baskin, of Abbeville, and one of checked Cotton Homespun, by the same lady, both of which are highly creditable to the skill and industry of that lady.

ROBERT W. GIBBS, Chairman.

—

The Committee on Marl, to whom were referred several communications, viz: Mr. Edmund Ruffin's "Marling Facts and Estimates"—Mr. Ravenel's account of the number of acres marled, and certain experiments in his neighborhood—Mr. Brisbane's and Mr. Holmes's experiments—report: That they find all these papers of great value, and recommend that they be published in the Planter.

They also report that they have awarded the Ruffin Premium to Mr. Holmes, of St. Andrews', for his well conducted experiments in marl, as applied to Cotton, Corn, and Potatoes.

WM. M. MURRAY, Chairman.

—

These awards were made, and the cups awarded; and on motion of Maj. Felder, it was ordered, that a ten dollar silver cup be awarded at the next Anniversary, to the lady who displays the best silk dress, of her own manufacture.

Hon. Judge Butler was appointed to address this Society at its next semi-annual meeting, on the last Wednesday in July.

At the instance of an invitation extended from the Newberry Agricultural Society, it was agreed that the semi-annual meeting in July of this Society, be held in Newberry village.

The following officers were elected for the ensuing year:

Whitemarsh B. Seabrook, President.
Hon. J. R. Poinsett, Anniversary Orator.
Chan. B. F. Dunkin, 1st Vice-President.
Chan. Harper, 2d " "
Whitfield Brooks, 3d " "
Hon. J. B. O'Neal, 4th " "
Hon. P. Butler, 5th " "
Hon. J. M. Felder, 6th " "
Dr. R. W. Gibbs, Corresponding Secretary.
Dr. J. B. Davis, Recording Secretary.

The President returned thanks for the continuance of his seat.

On motion of Dr. Gibbes, it was

Resolved, That this Society recommend to its members, and to the local Societies of the State, the necessity of sustaining the Southern Agriculturalist, published in Charleston, and the Carolina Planter, published in Columbia.

Hon. R. W. Roper, now delivered an able Address, which, after a motion of thanks, was ordered to be published.

Thanks were returned to Mr. Russell for his display of flowers at the Exhibition.

The Society now adjourned, to meet at Newberry Village, on the last Wednesday in July.

J. B. DAVIS, Rec. Sec'ry.

A Venerable Bible.—At the Anniversary meeting of the American Bible Society, an old divine from New Hampshire, called *Father Robbins*, held in his hand the identical Bible upon which the members of the *First Congress* and President Washington were sworn into office, and containing the names of all those old worthies written on its pages. These, said Mr. Robbins, were Bible times—and these, Bible men, and God blessed and prospered their labor; and under these men the country was prosperous. God grant, sir, said he, that we may again have such rulers and such times!

WOOL-GROWING.

There is every evidence that we shall have for years to come, a large and profitable demand for wool. The establishment of a reasonable protective tariff for the raw material, as well as the manufactured article, will, if persevered in, of which we can not allow ourselves to entertain a doubt, afford remunerating prices to the wool-growers of our country, till we have reached a production fully equivalent to the demand. What data may be assumed, as furnishing a correct estimate of the proper maximum of supply, would probably puzzle the shrewdest writers on political economy. We have, as elements properly entering into this estimate:

1. The quantity now raised in the United States beyond the coarse Smyrna and South American wools, costing 7 cents and under per lb., at the place whence last imported, on which the duty now levied is 3 cents per lb., and 5 per cent. ad valorem. On all wool costing over 7 cents per lb., the duty is 3 cents per lb., and 30 per cent. ad valorem.

2. The gradual substitution of a better grade of wool, (as the supply augments and becomes cheaper,) for carpets, blankets, and many of the coarser fabrics, which are now made from the coarse wool above mentioned; as it is an established fact, that an equal weight of a fine staple, is much more durable than the same quantity of an inferior grade.

3. The supply of the finer sorts of Saxon wool, now imported for the best qualities of broadcloth, cassimeres, &c. I am not aware of the quantity of this description of wool annually imported under our present tariff, but judge it to be considerable, from the fact that I was assured last year, by a manufacturer, that he had just ordered 50,000 lbs.; and a dealer told me that he had imported from London (the great wool market not only for England, but for the continent of Europe also) a much larger amount, for consumption in the eastern states, during the last season.

4. The rapid increase of our own woollen manufacturers, (our tariff remaining as it is,) and the manufacturing within ourselves, of nearly all the finer descriptions now imported, of broadcloths, cassimeres, fancy goods, shawls, booking, carpets, and rugs of the choicest qualities, (Brussels, Royal Wiltons, &c.,) blankets, worsted stuffs, bombazets, bombazines, mousselines de laine, &c., &c.; the raw material for which, is in all cases, furnished of a foreign growth.

5. The increasing demand from the increase of our population.

6. A demand augmented beyond the ratio of increasing population, consequent upon the prosperity of the country and the diffusion of wealth, which must inevitably accrue to our country, if we have the wisdon to maintain our present pacific relations abroad, and our protective policy at home.

7. The application of woollen fabrics to new and unforeseen purposes, as our manufacturers advance; such as their use by paper makers, carriage-makers, &c.; and their substitution for leather, cotton, silk, furs, &c.

8. The eventual exportation of wool, and the manufactured article to foreign countries.

That the exportation of wool from the United States is not a remote or improbable event, the policy of our own, and foreign nations continuing as they now are, will satisfactorily appear to intelligent minds, on a slight investigation. We have as peculiar advantages for the production of wool in this country:

1. Millions of acres of unoccupied land, every way precisely adapted to this object, a large portion of which, is not suited to any other profitable production. Thus we have, in addition to the measureless acres of prairie and other fertile, tillable land in the west and south, the great chain of the Alleghany, and its collateral mountains, reaching through twelve degrees of latitude and as many of longitude, throughout nearly their whole length and breadth, but especially as they recede from the north; all of which vast piles, and the innumerable valleys that everywhere skirt their sides, and which are now entirely unused, or occupied only to a very limited extent, are destined, ere long, to the support of countless flocks.

2. The adaptation of our soil and climate to the growth of a fine staple of wool; and the foregoing together with a dry and rolling surface of land, and innumerable supplies of fresh water, which almost everywhere abound, secure to sheep a healthful growth, and vigorous constitution.

3. The economy of labor in prodncing wool. The average time of an intelligent, able-bodied man throughout the year, will, on a good farm, well arranged for the purpose, and with suitable fixtures, provide the winter food, and give all the attention required, to a flock of 500 at the north, 600 in the middle, and probably, even more than this in the southern states.

We have examples the present season, of a choice Saxon flock producing 2⅞ lbs. of wool each, at an average price of 68 cents, or nearly $2 per head; and of another Merino flock producing over 5 lbs. per head at 48 cents, or $2.50 each. This would yield, for the productive labor of a single individual, inclusive of capital for the flock, land and fixtures, (and many flock-masters consider the lambs a full equivalent for all these,) from $1,000 to $1,500 per annum. What other agricultural occupation will produce one half as much? The above statement is predicated on the choicest sheep; but as these are as easily supported as the worst, it is not presuming to much on the intelligence of Americans, to suppose they will not long hesitate to follow where it is manifest their interest leads.

4. The cheapness of transportation. A pound of good wool in the European market is worth from 30 to 100 cents, and some, when thoroughly cleansed, even much more than this. Flour and grain is worth from 2 to 4 cents per lb., and beef, pork cheese, lard, &c., from 5 to 10 cents; and although from its increased bulk the former may be charged at double the ship-freight of the latter, yet this would be hardly appreciable in its market value; while, with the other agricultural products, it sometimes reaches beyond 50 per cent. of their worth, even in the place of consumption.

5. England is the great wool market for the world, and although it is computed she has 50,000,000 of sheep, they but partially supply her own manufacturers. And England manufactures a vast amount of the finest kinds of wool, scarcely a pound of which she raises within her own island territory. Her supply for all this comes from abroad, and after the quantity sent by her Australian and other provinces, she will as readily take of the United States as any foreign nation. It is probable that a large portion of her sheep lands are unsuited to the production of fine wool, and it is certain her management and policy are decidedly against it. Food for her millions of human beings, as well as food for her woollen machinery, is her object; hence her policy, and the almost universal practice of keeping the mutton sheep, the long and middle wools, neither of which can ever make anything but the coarser fabrics. The duty now levied on wool in England is but one cent per lb. on its value of 24 cents or under, and two cents per lb. on wool costing over 24 cents per lb.

6. The restrictive policy adopted almost throughout Europe, with regard to our agricultural products, while they amount to an entire prohibition of nearly every article of human consumption, (wholesome, nutricious, and abundant food, being generally deemed by their rulers articles of superfluity to the ruled,) yet what is essential to them as articles of traffic or of manufacture, out of which money can be made, as cotton, wool, &c., they readily admit on favorable terms. A large part of Europe is now so fully stocked with people, as to be incapable of multiplying sheep in the ratio of the demand for their fleeces. And if the peace policy is to to be continued there, as we see no improbability of its being, its increase of inhabitants must soon drive out sheep where they now exist. The ratio of supply will be, therefore, inversely as the demand. Where, then, can that deficiency be as well made up as in America? and what more rational than for the shepherds of hundreds there, to transfer their flocks to this country, and become the shepherds of thousands here?

With all our peculiar advantages, then, of cheap land, every way adapted in climate, soil, and position, to the healthful maturity of the animal, and the perfection of the staple of the wool; the large returns for the labor bestowed; the trifling cost of transportation; the incapacity of the largest manufacturing kingdom in the world, (now and always most dearly and most extensively connected with us in commerce,) for raising any of the fine wools, which enter largely into her consumption; and finally, the restrictive policy of foreign nations, which exclude our bread-stuffs and eatables, but admit, wherever they can use them, advantageously, the raw material for their manufactures, there is every probability, ere long, of a large demand for wool abroad.

One word to our sheep-owners, as to the kind of wool to be grown. The finer you can get the wool, with a large fleece, and good constitution in the animal bearing it, the more profit. In the neighborhood of good markets for mutton, there is an exception in favor of the mutton sheep to the extent of the demand for the carcase. And it is probable there can be thus raised, all the long wools required for our worsted stuffs, if not, it will be profitable extending the long wools into the interior, to the full supply of that demand. But remote from markets, the best Merinos, and most hardy Saxons, are beyond all doubt the most profitable. It will pay liberally to the flock-master, to select the very best the United States affords, and we could wish, and hope, they may see their own interest in immediately selecting some of the best specimens from the royal flocks in France and Spain, to refresh and re-invigorate the flocks, impaired by injudicious mixtures in our own country.

It may be proper enough to add, that *soil* has much to do with the softness and perfection of the fleece. A clay or loamy soil improves the fibre of the wool, making it finer and more soft and pliable; a sandy or silicious, and a calcareous or limestone soil, renders it stiff and harsh. The first improves, the last deteriorates, not only the fleece of the individual, but also the progeny. Thus, time may produce an essential change in the character of the race, without reference to any other consideration, than the quality of the soil on which they are reared and sustained.

Climate, and the rutting time, we ought to look to also, on every philosophical principle, as having an influence on the fibre of wool. No exception occurs to us of animals in equatorial regions, possessing a large, close, and fine covering; and none in the arctic, of such as have thin, hairy coats. Nature seems to have made no exceptions to this most rational and merciful arrangement. Should we not therefore look, with every probability, to our fine-woolled sheep sustaining the character of their fleece at the north, and to a deterioration of the same class at the south, in future generations? We know that the reverse of this is claimed by some observing and intelligent breeders of much experience, but we apprehend without sufficient data. We can easily conceive of sheep removed southward, improving the softness of their fleece from the increased perspiration and yolk thrown into it, from the higher temperature to which they are subjected. But this is a forced and unnatural effect, which nature, by her slow yet certain operations, we think, will effectually exert herself in removing from successive generations. By taking advantage of the period of conception, and having this take place when the parents are under the influence of the severest cold of the climate, which should be continued with the dam during gestation, if possible, may we not expect that the fœtus will have impressed upon it, which it will maintain through its maturity, a constitution and covering best suited to the condition of its incipient existence?—

Reason, we think, must teach us to look for such a result; and by this means, the prejudicial effects of climate may be arrested, or partially postponed; though in the end, the forementioned result seems inevitable. What but the scorching sun of Africa has given its present constitution to the negro; and the mildness of the temperate zones the character and constitution of the Circassian and European races? It is readily admitted, that the mountainous region of the South is not liable to this objection, as their increasing altitude diminishes the temperature, and is a full equivalent to a removal north. Nor do I see any reasonable objection to the rearing of the fine-woolled sheep on the low lands of the south, as any anticipated deterioration of staple, may be, in a great degree, obviated by the use of bucks reared in the north.

When the great advantage is considered, of the ease and economy of renovating soils and sustaining them in a high degree of fertility, by the keeping of sheep, I need not urge the system upon the intelligent agriculturist. Indeed, where lands have been cropped interminably, with wheat, rye, and corn, at the north, and wheat, corn, tobacco, and cotton, at the south, I know of no other self-sustaining system of renovation, that can be adopted. Lime and plaster, where economically obtained, may do it partially, but other manures will be necessary to carry out the work of regeneration. Where shall they be procured at a cost that will enable their owners to sustain a successful competition with the occupants of newer and more fertile lands, somewhat more remote? We can conceive of nothing more suited to the object than sheep. They clean the land of almost every noxious weed, drop most of their manure on the highest lands where most needed, and require little attention, for all of which they pay double; first, in the produce of a lamb, and second, in their fleece. They are also certain to build up, in an intelligent, industrious community, a manufacturing policy, which gives a profitable and pleasant employment to a supernumerary population; affords an enlarged market for miscellaneous agricultural productions, and in addition to all their collateral advantages, furnishes to the country, their fabrics at a cost, lessened by all the expenses of a double transportation. Surely, it is needless to urge the adoption of a system, fraught with so much advantages, upon the intelligent planters of the south and west, a people who have, in less than half a century, extended the annual production of cotton, from 2,000,000 to 600,000,000, lbs. The energy displayed in augmenting a single crop, three hundred fold, in so brief a time, is adequate to the succesful adoption of any policy, commended to them by so many intrinsic advantages.

R. L. Allen.

Buffalo, Sept. 20, 1844.

MEANS OF CHECKING RUNAWAY HORSES.

When a Canadian family party, travelling in winter over ice-covered rivers and swamps, is so unlucky as to cross a place where the horse sinks, they save him from drowning, and themselves from sharing the same fate, by pulling a rope so arranged that it instantly chokes him. The water being thus prevented from entering his gullet or windpipe; he floats on the surface, and it only requires a long and firm pull to bring him to solid ground, when, the rope being relaxed, he quickly recovers his wind, and is ready once more to start on his journey. This plan of saving a horse by suffocating him is spoken of by the Canadians as an equally effectual and safe means of attaining the desired end, and it is in universal practice. A similar means of stopping runaway, and subduing infuriated horses, whether in riding or driving, has lately been adopted by Mr. Miller, an ingenious saddler, of Lothian-street, Edinburgh, not in consequence of any knowledge of the Canadian plan, but as an original idea. It consists of a rein composed partly of thread-covered cat-gut and partly of common leather, one end of which is attached to the bridle at the top of the horse's head, while the other rests at the pummel of the saddle, or on the splash board or coach box, as the case may be. Running upon the cat-gut part by means of loops, is a short cross-piece of cat-gut, which rests against the windpipe of the animal, ready to be pulled up against that organ by taking hold of the nearer end of the rein. A quick and firm pull, to stop the breathing of the animal is all that is necessary to bring him to an instantaneous pause. He may be in a state of panic, and running off with the bit between his teeth in spite of every ordinary means of checking him; but no sooner does he feel the stricture on his breathing, than he is conscious of being outwitted and nonplussed, and becomes instantly as quiet as a lamb; at the same time he keeps quite firm on his legs—the check not being by any means calculated to bring him down. On the contrary, the position in which it places the horse, his shoulders being brought up, and being pressed back upon his haunches, the check is indeed eminently calculated to keep him up. A horse in a gig fitted up with a safety rein, was lately paraded before ourselves in one of the streets of Edinburgh, and the animal was several times in the height of his career (once when coming rapidly down hill,) brought to a sudden stand. We understand that the safety rein is coming rapidly into use; and friends as we are to every thing that tends to diminish evil, and promote the convenience and agreeableness of human life, we cannot but wish to see it in universal application. We feel assured, that henceforth, by means of this rein, accidents from running away, or other violent conduct of horses, may be altogether prevented.—[*Chambers' Edinburgh Jour.*

From the American Agriculturist.

THE POLICY OF AMERICAN FARMERS.—No. 1.

If the farmers of the United States are ever to reap the full benefit of their labor, they must do something beyond raising the largest amount of products, at the least amount of expense. An enlarged and comprehensive view of our circumstances and commerce as a nation, and its internal and foreign relations, and a general, systematic, and concerted action, on the part of the agricultural interests, founded upon such information, is indispensable to their realizing all the advantages to which they are entitled.—We see this intelligent and embodied effort in every other profession and craft; the clergy, acting through regular and frequent assemblies, for the more effectual promotion of their more benevolent objects; the physicians, associating for the protection of their profession under law, and securing to it the highest amount of intelligence; the lawyers, in controlling legislation so as to secure to the profession the largest bill of fees; the mercantile and commercial interests, by their boards of commerce and other active and well remunerated agents, influencing national laws and commercial regulations for their own benefit; the manufacturing and mechanical interests, by concerted movements, effecting the same objects for their own pursuits; and even the laboring classes, by the well-drilled and efficient *strikes*, not unfrequently compelling an attention to their own interests, beyond their intrinsic merits. The farmers, it is true, are well, indeed amply, protected by an impost on the objects of cultivation in this country sufficient to exclude every article they are now engaged in producing. The staple productions, grain, vegetables, beef, pork, cotton, &c., have always been fully protected, and by the late tariff the duties have been so increased on wool, hemp, silk, and some other products, to which Americans have been recently turning an increased attention, that they can now defy competition from abroad. It is not the want of higher duties on their crops, which they now require; it is a well-organized, efficient, intelligent, central board, supported by funds from the general government, which, procuring information from every portion of our wide-spread union, and from every foreign nation, with which we can have any profitable traffic, will be enabled to suggest new and profitable objects of cultivation; give additional value to such as are already receiving attention, and mature and communicate for acceptance, such modifications of adopted systems, as the constantly varying circumstances of the country require. Such a board was recommended by the illustrious Washington, in his last message to Congress, Dec. 7, 1795, and had his wise counsel been at that time adopted, and efficiently carried out to the present time, we might confidently have looked for a success and intelligence in American agriculture, far beyond anything that the world can now exhibit.

That the creation of such a board, is at any time within the power of our landed interests, is clearly manifested in the fact, that every officer of our government, legislative or executive, is either directly or indirectly elected by the popular vote, and at least two-thirds of this vote is given by those whose entire support is derived from agriculture, and one-half of the remaining third is under their controlling influence, so that not less than five-sixths of the popular voice can be brought to bear in favor of any measure calculated to promote this object. The neglect, hitherto, to secure the rightful interests of this great pursuit, evinces an apathy and indifference, alike discreditable to the intelligence and patriotism of the agricultural community. R.

Improved Farming in Virginia.—Mr. H. R. Robbey, near Fredericksburg, Va., gives us the following favorable account of the effect of agricultural papers in improving the husbandry of its neighborhood: "When I commenced farming, I determined to try the new system of husbandry, because I saw the old plan would not do; farmers were all going backwards, or getting poorer every year; my new neighbors laughed at me, when they saw me occupying so much of my time in hauling mud and sods from the swamps to put in my manure pile, and asked where I got that notion from. My reply was, from the Cultivator. They laughed still more, and called me the book farmer, said I would soon find out my folly, and go back to the good old custom, as they call it. Many of those men have acknowledged since, that I have been pursuing the right plan. I have now eight barrels of corn growing, where six years ago one barrel could not be grown; and all my information has been derived from agricultural papers. Some of my neighbors, for two or three years past, have been taking the Cultivator, and you can perceive an improvement upon their farms already. They are now not content to put up with the bare necessaries of life. A spirit of improvement seems to have taken hold of them; they begin to cultivate improved varieties of fruit for market and their families; thus adding profit and pleasure, where neither could be found before they began to read agricultural papers."—*Alb. Cultivator.*

Wool Growing and Cotton Manufacturing in Mississippi.—The following is from the Natchez Courier of the 11th ult:

"We were yesterday shown, by our valued friend, Samuel T. McAllister, Esq., a couple of samples of Wool sent to him by Mr. James Brown of Yazoo county. The Wool was of the finest, softest texture, far surpassing any we have ever seen. We were surprised when told that such an article had been raised in Mississippi, where, until the few years past, but little attention had been given to such products, the cultivation of Cotton having occupied the entire time of our farmers. Mr. Brown sends Mr. McAllister a bale of Wool weighing 400 lbs. of excellent quality, which he desires to exchange for Cotton Goods of Mr. M.'s manufacture, and writes that he will be able in a few months to send him another bale of Wool of superior quality.

"It is certainly pleasing to see that our planters are beginning to take an interest in Mr. McAlister's enterprise of manufacturing, and to see what advantage patronizing him will be to them. Mr. M. is progressing finely with his factory, having as much employment as his force can despatch, and making various articles of a quality inferior to none in the Union."

PREMIUMS FOR THE BEST MANAGED FARMS.

To the Editor of the Marlborough Gazette.

Having already received notice from two gentlemen, competitors, addressed to me as first named of a committee to award the premium offered for the best managed farm in the county, it seems proper that I should state, in this the most convenient form to all parties, that it will not be in my power to undertake the trust with which the Agricultural Society of Prince George's has honored me. I am not the less grateful for the compliment which such an appointment conveys, for it assuredly implies a belief that the persons so delegated have not only taken a deep interest in the general subject of agriculture, but that their fondness for it and conviction of its paramount importance, has led them to inquire into and reflect upon what *constitutes good management*, both as to principles and practical details.

It is not easy to imagine any duty that requires better judgment or more unyielding impartiality than that of *awarding such a premium*. How many things are to be considered! The extent of the farm to be compared, not only with others, but with the resources at the command of the proprietor—such as capital in money, in labor, in natural fertilizers, and in elements requisite for compounding manures, &c. The time the farm has been in possession of its present proprietor, with its original and present condition, and in that connection what have been his extraneous aids and facilities, and how far improvements have resulted from his own sagacity and forethought, or from the knowledge and experience of his manager—for the manager sometimes makes heavy crops under an improving system of husbandry, not by the directions, but *in spite of the owner*.

All these and many other things are to be taken into the account, and, after all, there will be liability to error, as well from overlooking important facts, as from giving undue weight to minor considerations; still, with such colleagues as were on that committee, I would, if my duties here would permit, most gladly have joined in the inspection of the farms to which they are invited, expecting to derive, not only peculiar pleasure in visiting their proprietors, but much information from observing their practice, and from being associated with gentlemen of so much experience and judgment. Indeed, it is difficult to conceive any thing more agreeable and recreating to a passionate amateur of the *country*, and all that belongs to country life, than would be a comparison of the claims of competitors for *such premiums*. The thorough sifting that should be given to the candidate would be a caution to all indolent and *unthinking* planters! The catechism should be begun by a close examination of his personal agency in the concern, to know how much of the results were the fruits of his own *thoughts* and directions. But that agency is not always to be measured by the time of a man's rising, or the constancy of his presence on the farm. There are some men who have things so *systematized*, that they can manage better when sick, or occasionally from home, than others who rise before day and are "fretting and fuming" from morning to night. The gentleman, Col. N. Bosley, of Hayfields, who took the premium "presented by the hands of General Lafayette," for the best managed farm of that year, was half his time bed-ridden, and had no overseer; but he knew every day what was doing, where it was doing, how it was doing, and *why*—yes, and that's the great point—*why* that particular thing was being done at that particular time. He made an independent fortune with *hay* as his staple, on a very hilly, stony farm, sixteen miles from Baltimore.

I had lately, by special invitation, and by the kind permission of my *Boss*, the satisfaction to dine at Indian Hill, the premium farm of Massachusetts, to the proprietor of which the premium was awarded, not only for the *best managed farm*, but for the best *specimen of under draining*, and the best system of *keeping farm accounts*. Who might not be prouder of such premiums than of military achievements, and sometimes negative service without achievements, for which our wise, thoughtful, republican Government, representing two-thirds farmers, awards the *highest honors, the largest life salaries, hospitals, pensions, &c.*

The proprietor of that farm, where I met some of the most accomplished agriculturists of Massachusetts, is half the year absent in the South. But he has things so set down and systematized, that he is constantly and exactly informed of what is going on. Every man is *numbered*, and every job of work to be done is *numbered*, and he knows that on a given day number so and so was at work on job No. 7, or 3, or 2, as the case may be. His people all rise at five, A. M., by the *ringing of a bell*, as in a ship or a factory; and breakfast by candle light, he taking his seat, when at home, at the head of their *breakfast* table, just to see that all are there, and that *all is right*. After all is fairly under way, he is ready for his own family breakfast table, where, as well as throughout the house, you find a neatness, good order, and abundance, corresponding with if not even excelling the out-door management. In fact, the neighbors do hint that "two heads *are* better than one!" Certain it is, that I never saw a more unique, antique, venerable looking mansion outside, nor one *in* which reigns a more charming air of quiet order, good management, and domestic taste and harmony.

To economize time, even the kindling is in the kitchen "the overnight." The hash is ready only to be "warmed up," and breakfast with coffee is all ready for the laborers in the "twinkling of an eye" after the bell rings at five.

The laborers—willing, steady, and constant—are all white men, generally Scotch, sometimes Irish, hired by the month. On that point I refer to his answers to questions propounded by the Society. When all is going on, as it goes every day, as smooth as clockwork, Mr. Poore, rich "in all the qualities that give assurance of a man," is then ready to take his family or his guest, as he did me, in his coach and "four in hand," and that in his own hand of preference, any where over delightful roads and a magnificent country at the rate of eight miles an hour! I only mention it to show that "best management" does not imply eternal drudgery, and the absence of all social enjoyment. At Indian Hill farm, as on every farm in New England, there *is a place for everything and everything is in its place*. You don't see a bridle on the ground here and a swingletree in another place; sheep skins and sometimes the sheep themselves eaten up by dogs, and harness lying out in the weather; axes scattered here and hoes everywhere; carts broken and doors and gates off the hinges; negroes hunting here and there for the spade, or for him that had it last, to know where he left it; galled horses with clogs on their feet and yokes on their necks; and oxen, as I this morning actually saw a yoke in Washington, one pulling one way and the other the other way with all his might, with a negro on each side armed with sticks to drive them from one side to the other. There (in New England) one yoke does at least as much as three do here. They are all fat enough for beef the year round, and are driven rather by *signs* and with very light whips than by violence. One must go to New England to have an idea of the power, the docility, and the great usefulness of a single yoke of oxen.

At Poughkeepsie, in the plowing match, there were seven single span of oxen and two of horses started for the premium, each managed by a plowman without a driver; the prize was taken by a span of *oxen!* The whip of the plowman was lighter than the *beach switches*, which I remember well, and to my great terror were kept standing in the corner of a log-cabin school-house in Calvert county, under the dread government of the never-to-be-forgotton Robert Spicknall.

How much I should have been gratified could our committee, with the estimable and efficient Secretary of the Society, have been with me to witness many things that I saw on an almost literally flying visit to Massachusetts and New York. I could "spin a yarn" worth hearing out of it, if I had time; one that might make the woof and the web of an address, for which I see "by the papers" I have been "set down" for your next meeting; but close confinement here, and the disordered state of my health, will not allow me to comply with the wishes of the society in that respect.

Among other places, I made a visit to Marshfield, and there ate *chowder*, made chiefly of codfish, taken in the "deep waters of the dark blue sea," by the hand, hook and line of the great American commoner himself.

Arriving before dinner he took us first through his cornfield, by way of an *appetiser*, and what with the thickness of the corn and the number of the pumpkins on the ground, you might as well have been dragged through a Mississippi canebrake. I could not help thinking what glorious music a good pack of hounds would make in it, in pursuit of a gray fox or a wild cat. A large portion of the field would undoubtedly yield eighty bushels of corn to the acre, and yet corn of the same *height* with us would not produce twelve bushels. Mr. W. was proud and had reason to be of his large field of "*swedes*," his twelve beautiful heifers, and of his Southdown sheep, of the stock he selected in England, of which he generously tendered as many as I would accept, which was a buck and two ewes, to go into Prince George's county. But of all things he seemed to be fondest of and most familiar with his *noble oxen!* some six or eight yoke, that would average, in the shambles, at least twelve hundred. He seemed, too, to felicitate himself particularly in the shade of a venerable and *magnificent elm* near his house, "*Religione patrum multos servata per annos*," its graceful branches extending over a diameter of a hundred feet.

You will receive in this hasty letter the answers of Mr. Poore, of Indian Hill, to the questions propounded by the Society. It is probable that many of your readers will peruse them with as *much benefit*, if not interest, as they would do *—some other things.*

Respectfully,

J. S. SKINNER.

EXTRACT

From Mr. Whipple's Address before the Merrimack Co. Agricultural Society, at Warner, N. H. Oct. 14.

"We are very much in the habit of cultivating too much land. Certain it is that one acre well cultivated and richly manured, will produce more than two acres indifferently cultivated—and then you save about half the labor—a very important item. The farms in this county and in the State, now under cultivation, are capable of producing, by proper and judicious managemennt, from 25 to 50 per cent. more than the present yield. I think I do not exaggerate in my estimate. There is one store in Concord which sells annually twenty thousand barrels of flour. Suppose th t is one-fifth part of the quantity sold in the State—then there would be one hundred thousand barrels of flour consumed yearly. Estimate this at the lowest price, say $5 per barrel, and you have the sum of $500,000 expended for the single article of flour, beside the other grain which is brought into the State. Could you believe this? Half a million of dollars is yearly paid from this State, for bread stuff raised by western farmers. Certain I am from inquiry, that the estimate I have made is small.

"You ought to raise your own bread stuffs; you might easily supply the wants of every consumer in the State. There is no reason, no excuse why we should be dependent upon our western farmers for such an immense amount of bread stuffs. We have soils well adapted for the growth of every kind of grain, and we as farmers, are as capable of producing large crops as the farmers of neighboring States. That there should be such a deficiency for our home consumption, is altogether unaccountable. We ought to encourage our sons and young men to remain here on the beautiful hills and vallies of our own native State and cultivate our lands, instead of advising them to go West. It is a

mistaken notion, that young men can do better West than they can do here. We have lands enough in this State, if properly divided, to give labor to double the present population. We have advantages here that you cannot have in the western country; and all that is wanted is a contented mind and a determination to make our own New Hampshire a vender of bread stuffs rather than a purchaser. There is something radically wrong in suffering such an import of bread stuffs into this State; and by you, gentlemen farmers, the wrong must be righted. We have water power here that will make us independent, if we only cultivate the soil and supply the wants of the consumers who are engaged in our manufacturing establishments. We shall always find a ready market for everything that the farmer raises."

From the Albany Cultivator.

THE OLIVE.

Messrs. Editors:—Dr. Olin, describing the soil and productions of Palestine, speaks thus of the olive:

"But this is the proper region for the olive and the vine. Anciently, these hills were covered with orchards of fruit trees and vineyards, and the world does not, probably, produce finer grapes, figs and olives, than are annually gathered about Hebron and Bethlehem. One acre of the flinty surface of the Mount of Olives, carefully tended in olive trees, would yield more, through the exchanges of commerce, towards human subsistence, than a much larger tract of the richest Ohio bottom tilled in corn. Most persons know little of the variety and importance of the uses to which the fruit of the olive is applied in the Eastern nations and in some of the Southern countries of Europe. Large quantities of the berries are used by the inhabitants, and exported as food; but the principal value of the olive consists in the delicious oil that is extracted from its fruit. This is used upon the table and in cookery, as the substitute for both butter and lard. It is universally burned in lamps, and instead of candles, which are nearly unknown in the east. It is the principal material used in making soap."—*Olin's Travels, Vol. II., p.* 430.

Mr. Jefferson, in 1787, wrote as follows:

"The olive is a tree the least known in America, and yet the most worthy of being known. Of all the gifts of Heaven to man, it is next to the most precious, if it be not the most precious. Perhaps it may claim a preference even to bread, because there is such an infinitude of vegetables which it renders a proper and comfortable nourishment. In passing the Alps, at the Col de Tende, where there are mere masses of rock, wherever there happens to be a little soil, there are a number of olive trees, and a village supported by them. Take away these trees, and the same ground in corn, would not support a single family. A pound of oil, which can be bought for three or four pence sterling, is equivalent to many pounds of flesh, by the quantity of vegetables it will prepare and render fit and comfortable food. Without this tree, the country of Provence and the territory of Genoa would not support one half, perhaps not one-third, their present inhabitants. The nature of the soil is of little consequence, if the soil be dry."

"In Italy, I am told, they have trees of two hundred years old. They afford an easy and constant employment through the year, and require so little nourishment, that if the soil be fit for any other production, it may be cultivated among the olive trees without injuring them."

"Notwithstanding the great quantities of oil made in France, they have not enough for their own consumption, and therefore import from other countries. This is an article, the consumption of which will always keep pace with its production. Raise it, and it begets its own demand. Cover the southern States with it, and every man will become a consumer of oil, within whose reach it can be brought, in point of price. If the memory of those persons is held in great respect in South Carolina, who introduced there the culture of rice, a plant which sows life and death with almost equal hand, what obligations would be due to him who should introduce the olive tree, and set the example of its culture!"—*Mr. Jefferson's letter to Thomas Drayton, dated Paris, July* 30, 1787.

"I am persuaded there are many parts of our lower country where the olive tree might be raised, which is assuredly the richest gift of Heaven. I can scarcely except bread. I see this tree supporting thousands among the Alps, where there is not soil enough to make bread for a single family."—*Mr. Jefferson's letter to Mr. Wythe, dated Paris, Sept.* 16, 1787.

Here is surely ample testimony as to the estimation in which the olive was held in modern times, by those acquainted with its uses. If evidence is wanting as to the estimation in which the ancients held it, we have only to refer to the frequent mention made of it in the historical parts of the Bible, and the beautiful allusions to it so frequent by the Hebrew poets—to the beautiful fictions among the Greeks about its origin, one of which is mentioned by *Apollodorus Atheniensis*, who tells us how, in the reign of Cecrops, Neptune, smiting the earth with his trident, made the sea flow at his feet; how Minerva, determined to outdo his marine godship in beneficence, called on Cecrops to bear witness to what she was going to do, and made an olive tree spring from the ground; how these divinities quarreled about the value of their respective gifts to Attica, and Jupiter, to settle it, appointed twelve gods to determine the question, which august jury of divinities gave a verdict in favor of Minerva; and to the rank assigned to it by Collumella among the Romans, as being the first among trees. Yet in the whole of the United States, I know of but two or three instances, in which attempts have been made to introduce the culture of this tree. Long ago, indeed, the colony of Greeks settled at New Smyrna, in E. Florida, had planted the olive, and only sixty years ago there were large trees marking the site of that settlement. Recently, Mr. Cooper, of St. Simons, and Mr. Spalding, of Sapelo, Georgia, have tried its cultivation, I think, with success; and in the garden of Mr. Rose, at Macon, I saw recently a flourishing tree which had thus far withstood the winters there. I suppose the general impression that it would not endure, without injury, the cold of our winters, has deterred cultivators from turning their attention to it; as it is known that the severe winter of 1807 destroyed a large part of the olive trees in the south of France; and as it is known too, that Humboldt, in his essay on the geographical distribution of plants had set down the olive as requiring a climate with a mean temperature of 57 deg. 17 m., the greatest cold being 41 deg. 5 m. Mr. Jefferson, however, says that when killed by frost, it will spring up again from the roots; so also says Mr. Hillhouse; and such is the experience of Mr. Spalding and Mr. Cooper. If the varieties cultivated in France were the only ones to be had, even their comparative tenderness ought not to be an objection to attempting their cultivation here. For all experience shows, and philosophy teaches, that plants of temperate climates, in time, by frequent reproduction from seed, adapt themselves to colder climates, in which, at first, they invariably perished. The Melia Azedarach furnishes a familiar illustration of this fact; and applying to the well known characteristics of the olive tree, the first and second of the laws of temperature, with respect to its influence on vegetation, as laid down by M. De Candolle, we may confidently conclude therefrom that it will adapt itself to our climate even sooner than the Melia.

Happily, however, there are varieties to which this objection cannot be made. "In the southern part of the Crimea, which lies between the latitude of 44 deg. and 46 deg. two varieties of olives have been discovered, which have existed there for centuries. They yield great crops and resist the frost."

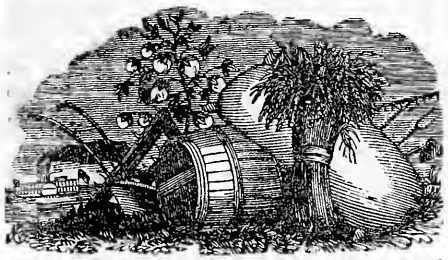
"These olives have been cultivated in the Royal Imperial Garden of Nikita, to preserve and multiply the species, with plants which had been received from Provence, and have endured the rigorous winters of 1825 and 1826, while those of Provence, in the same exposure, perished even to the root. Measures have been recently taken in France for the introduction into that country of these two precious varieties, *which are capable of resisting ten or twelve degrees of cold below the zero of Reaumur's thermometer---equal to five degrees above the zero of Fahrenheit."---Kenrick's Amer. Orchardist, 3d ed., p.* 333.

The nurserymen of the United States incur great expense in introducing such exotics as the Cedar of Lebanon, Garoga elyptica, Paulownia imperialis, Pinus deodara, &c. &c.:—all of which are very beautiful trees; but when they are said to be very beautiful and very rare, all is said of them that can be, with truth, except that they are very expensive. It is true that purchasers are found who are willing to pay high prices for them; and in this, those who import them, find their remuneration. By incurring an expense, not more, it is believed, than has been incurred in the introduction of any of the exotics above named, the olive of Nikita may be introduced. And if it stand the rigor of our climate, as it does that of its native region, may we not hope to see it, in a few years, spreading over the southern States, adding to the comforts and the wealth of our people? Once introduced, its propagation is a matter so very simple, that it may be easily disseminated to any extent in a very short time. Such men as Dr. Cloud, of Alabama, Dr. Phillips and Mr. Affleck, of Mississippi, I would suppose would not rest until they secured the introduction of the olive into their States, respectively. Mr. Affleck, especially, will surely not consider Ingleside complete, until an olive grove shall have been added to his establishment.

Dampier and Lord Anson, the former as far back as 1688, had described the Bread Fruit, as a most invaluable production of the Ladrone Islands. In 1787, persons in London, interested in the West India Islands, prevailed on the King of Great Britain to order a ship to be fitted out at the expense of the nation, for the purpose of introducing the Bread Fruit as an article of food, into the West India Islands. The first voyage, under Lieut. Bligh, was a failure. But the object was ultimately accomplished. The result, from some cause or other, did not answer the expectations of those who had taken an interest in it; yet they never regretted having made the effort, nor the charge made by it on the public treasury. Is it not a matter of higher importance to the southern States of our confederacy that the Nikita olive should be procured at the public expense? Look over the list of seeds and plants brought home by the Exploring Expedition—esttmate the whole at the highest value that can properly be set upon them, and altogether, so far as real utility is concerned, they are not equal to the value of the Nikita olive. Yet how they are cherished—with what care and expense they are preserved! The government of Great Britain incurs heavy expenses to introduce the Bread Fruit into the West India Islands; the government of France takes measures to introduce the Nikita olive into that country. Shall our government, established in all its branches, on principles of utility, and professing to be regulated in all its movements, exclusively by these principles, lag behind the old and decaying monarchies of Europe in enterprises like these? Shall it be said that in our republic, its exploring expeditions, undertaken professedly for the public good, shall belie the character of all our institutions, by preferring, in their collections, articles of show to those of utility? Jas. Camak.

Athens, Ga., March 10, 1844.

☞The Baltimore American says, the Post-Office Committee in the House of Representatives, it is believed, will present a bill reducing the rates of letter postage to *five* and *ten* cents, for distances under and over one hundred miles.



The Southern Cultivator.

AUGUSTA, GA.

WEDNESDAY, JANUARY 1, 1845.

☞ Those *Agricultural* journals with which we exchange will oblige us by directing to us at Athens in future.

Together with the gratulations appropriate to the season, we present to our friends the first number of the third volume of the Southern Cultivator. The favor with which the two preceding volumes have been regarded, encourage us to entertain high hopes for the future, that our efforts in aid of Southern Agriculture may have some agency in redeeming it from the reproaches it has had to submit to, in times past, and in awakening those engaged in it to a sense of their true interests.

Why do Southern fields and Southern rural dwellings so generally wear the aspect of exhaustion and dilapidation? The cause is to be sought for, certainly, neither in our climate nor our soil. For the climate of the Southern States—of Georgia, especially—is, beyond all question, the most delightful, in every respect, in the world. Travellers who have visited the south of France and Italy bear testimony to its superiority to the climates of those countries. Scientific gentlemen have recorded their observations in proof of the same fact. The late Professor Nicollet, had, in the service of the French Government, before he came to Georgia, visited nearly all the climates of the earth. He had no hesitation in declaring his preference of the climate of Middle Georgia to all others he knew anything of. And M. Valney, many years ago, stated without qualification that the climate of the United States, on the 35th degree of N. latitude, was, according to his experience, the best in the world. To all this may be added the uniform testimony of every Southern man who goes abroad, and, from personal observation, makes a comparison between other climes and our own.

And what a soil originally! Leave out of the comparison the alluvions of the Mississippi valley, and the Southern States, as regards native soil, were not surpassed by any other country:—and even now, after years of butchery, by careless and unskilful hands, in the means of improvement, and the facility of their application, and the certainty of success, the South is surpassed by few other lands under the sun. No one need hesitate one moment about the resuscitation of his soil. The means are at hand, if he will but make an intelligent search for them. The marl of the tide-water region, the clay and green sand of the middle country, the lime and plaster of the mountain district, and the luxuriant vegetation so peculiar to Southern climes, supply the means of improvement in ample abundance.

What country is there that can boast of so great a variety of useful and valuable productions in the same extent of territory. In Georgia, for instance, we have rice and sea island cotton and sugar on the sea coast; cotton and wheat, tobacco and silk, if we choose, in the middle country; wheat, gold, iron, coal, lime, plaster, and marble among the mountains; corn everywhere. On the whole earth, can this be equalled?

And how have these signal advantages been improved by our people? Let our worn-out fields and deserted homesteads answer, proving too conclusively that where nature is overbountiful, man is sure to be a spoiled child. The time has come, and now is, when the old practices which have led to this state of things must cease. Our planters must put in practice a new system of domestic economy. The present rates of profit on capital invested in agriculture will not allow of indulgences for the future like those we have enjoyed in times past. Comparative exemption from care, trusting to agents, buying luxuries and even food from abroad, unskilful and slovenly cultivation, clearing new land and wearing it out—all these things must have an end. Planters who intend to bid defiance to the sheriff, and expect to be able to look poverty in the face without dismay, must look closely after their own affairs, depending on their own skill and energy in the management of them; must dispense with mere luxuries; must make at home their own food and clothing; must apply themselves to collecting all the information they can get about the best modes of reclaiming and cultivating land; and to putting into rigid practice what they shall thus learn. Depend upon it, this change has to be made, and the sooner it is begun by all, the better will it be for all. And when it shall have been accomplished—when our planters shall properly esteem the importance of their pursuit, remembering the estimate that one thousand millions of men depend on it for sustenance, that nine-tenths of the fixed capital of the civilized world is vested in it, and that they are a part of the two hundred millions of men whose daily toil is spent in its operations:—when they shall adopt and act on the idea that plants are living bodies, requiring food for their sustenance and proper development, just as much as animals do:—when they shall distinctly understand that, the problem they have to solve, is, how to get the greatest possible amount of produce from an acre of ground, with the least possible outlay of labor, and the least possible amount of injury to the soil:—when our planters shall understand all this, shall steadily pursue the course that is forced upon them by this understanding, and by the present state of the agricultural markets of the world, and shall have put into practice the system of domestic economy suited to the new condition in which they are finding themselves placed, the sun will not shine on a more productive soil, nor on a happier or more thrifty people.

There is everything to encourage our planters in undertaking this reformation. No principle is better established, than that a soil originally fertile, though exhausted, may be easily, not only restored to its original fertility, but may be even pushed far beyond that point. It is true in theory, and is also true in practice. The success of the Flemish system of husbandry, both at home and in the county of Norfolk, England, and the experiments of Von Voght in Germany, prove what may be done even with barren soil. In England, every thirty-four acres of land has now to produce food for twenty people; yet Mr. Smith, of Deanston, a practical man, the inventor of the subsoil plow, says, "it is not at all improbable that Britain may become an exporting country in grain, in the course of the next twenty years." And we have the authority of Alison for saying that the introduction of the garden culture of Flanders, and the terraced culture of Tuscany throughout England, would at once double the already enormous production of her soil. In Virginia, the emigrants from New York are rapidly reviving the poorest worn-out lands of some of the poorest counties. Already some of our planters in Georgia are making ten bales of cotton to the hand on lands that had been exhausted. Ninety-six and a quarter bushels of corn have been gathered from one acre in Hancock county. Indeed, no man has yet attempted to prescribe a limit to the productive powers of the soil. Add to this, the fact that agriculture is rich in the trophies science has conquered for it, during the last few years. In nothing is the present age more remarkable, than in the improvements science has made in the commonest implements, and the light it has thrown around the commonest processes. For instance, how best to stock a plow—the best shape for the share and mould-board—the direction of the line of draught from the collar—the angle a hoe should make with its handle—why wheat will not thrive best on food that suits corn—the comparative value of food for cattle, in reference to the products of milk, cheese, butter, or fat—the nature of rust in wheat. There was a time when such things were thought to be beneath the dignity of science. But that time is past. Science is now beginning to be esteemed, by the tillers of the ground, as it really is—the refinement of common sense, guided by enlightened experience. And the time is rapidly approaching when it will accomplish for agriculture as much as it has done for commerce and manufactures, through its most wonderful agent the steam engine.

To aid, as far as may be in its power, in bringing about this most desirable state of things, will be the constant endeavor of the Cultivator. How far we shall succeed depends, in a good degree, on those to whose service our exertions are to be devoted. No man likes to work for thankless employers: neither will any man work for nothing, if he can help it. We don't plead exemption, in this respect, from the common feeling. If, therefore, the planters of the South expect to derive full benefit from this publication, they must sustain it zealously by both word and deed. We will do our duty faithfully, to the best of our ability, trusting confidently that the reciprocal duty of the public will be as faithfully discharged.

PLANTERS' CLUB OF HANCOCK COUNTY.—It gives us great pleasure indeed to publish, as we do in this number, the account of the late Fair of the Planters' Club of Hancock County. This Club, we believe, was the first that was formed in this State, and the result of its efforts thus far, is certainly such as ought to induce planters in other counties to form similar associations. Near one hundred bushels of corn gathered from one acre! It is not long since such a product was thought to be utterly impossible in Georgia. Now there can be no doubt about it; the Club have awarded a premium for the production of ninety-six and one-quarter bushels: and we do not at all doubt that in less than five years, the members of this same Club, continuing their enlightened efforts for the improvement of their county, will be called upon to award a premium for the production of *over one hundred and fifty bushels* to the acre.

We felicitate the Club on their determination to include pork and wool hereafter in the list of objects to be presented for premiums. This is exactly as it should be, and will lead the way in Georgia, we have no doubt, to a state of things in which we shall not be dependant on others for these articles of prime necessity.

Need we suggest to the intelligent members of the Club, that in undertaking to produce wool, the very first movement must be to exterminate the whole race of rascally dogs with which the country is infested from Dan to Beersheba. We have known attempts at wool-growing fail utterly from not doing this one thing.

The Clubs of Hancock, Greene and Morgan, are, we believe, the only ones at present in the State. But we confidently expect that in a very few years, almost every county in the State will have its club, and that all of them will be but branches of a great STATE AGRICULTURAL SOCIETY.

In Kohl's Travels in Ireland, page 115, Harper's edition, there is a reference to the uses to which sea-weed is applied by the People on the coast of Antrim. "One kind of a sea-weed," he says, "much liked for manure, is the *Laminaria digitata*, called sea-wrack, which is considered so serviceable, especially for potatoes, that it is a saying in Antrim that a sack of sea-wrack will make a sack of potatoes; although, in general, it is rather the quality than the quantity of this useful root that is improved by it. After every storm on this coast, the people come down in crowds from the mountains, to gather the sea-wrack for their potatoes, and in calm weather they run out far into the sea, and cut it under the water with sickles. Sometimes they take the little mountain horses in with them; but when the shore is too rocky for this, they lade their own human backs with the salt dripping manure."

It must occur to every one on reading this account, that the efficacy of this manure, in improving the quality of the potatoe, must be owing to the salt it contains. If this be so, the application of common salt with the manure usually applied, at the time of planting, must have a good effect. It is, at all events, worth the time and trouble of making the experiment, to know what the effect of the application will be in our climate. As the time for planting the Irish potatoe is approaching, may we not hope that experiments will be made, and that the result will be made known to the public through the medium of the Cultivator.

HEMP.—It has long been a matter of surprise to us that the culture of hemp was not attempted on the rich lands of northwestern Georgia. What we know of these lands compels us to believe that success must certainly attend the attempt whenever made. With a desire to aid those who may think of trying it, we intend to publish in the next number of the Cultivator, an essay on the culture of hemp, and its preparation for market, by the Hon. Henry Clay, of Kentucky. This will be followed by Judge Beatty's prize essay on the same subject, and various other papers, until nothing shall be left that is necessary to a full understanding of the whole matter.

There is great encouragement just now to undertake the culture, in the fact that the old tedious and laborious process of braking by the hand is about to be superseded, by a machine recently invented, by which, with an ordinary horse power, four hands can brake 200 lbs. per hour. The machine is called "Butler's Hemp Brake," and can be bought in Nashville, Tenn., for twenty dollars.

For the Southern Cultivator.

MR. EDITOR:—I herewith send to you the form of an abbreviated Almanac, which you might believe appropriate for an insertion in the first number of your third volume. It presents a facility of reference, which no other that I have ever seen does. The calculations have been made by myself, and I will guarantee its correctness. You can, however, dispose of it as you may think proper.

Very respectfully, Yours,

THOMAS GAILLARD.

"KEEP IT BEFORE THE PEOPLE,"

That the outrages perpetrated on PROPERTY IN THE SHAPE OF TREES, are at last arousing legislative and judicial vengeance. The robberies practiced openly upon gardens and orchards and door-yards, have long and keenly annoyed those who devote care and labor to the cultivation of fine fruits and the embellishment of their homesteads. This species of pilfering, so common with children, exerts a pernicious influence on the minds of the young and old; for those who plunder their neighbors this way while young, are commonly more or less tainted with thievish propensities in maturer life. "Train up a child in the way he should go, and when he is old he will not depart from it." Mark, then, the influence of example—of good and evil example—upon the minds of youth:—"We do not know," says the New York Express, "when we have been more pleased with a judicial decision than that which we find recorded in one of our late London files. A boy fifteen years of age, was convicted and heavily punished for breaking a bough from one of the trees in a public garden. The sitting magistrate, in passing sentence on the offender, took occasion to use the following strong and sensible language: "that although the damage in this particular instance was small, yet the practice of breaking trees occasioned great damage; and the inhabitants of the different squares were put annually to great expense, in consequence of these depredations. *Persons had no more right to take a branch from one of these trees, than they had to go into one of the houses and steal a piece of plate.*" We hope this will be 'recorded for a precedent,' in every court in this country."

There is a beautiful circumstance connected with agricultural emulation. In many of the pursuits of life, one man gets rich by making another man poor,—climbs the ladder by putting his feet on another man's shoulder; or he builds his own building out of the fragments of his neighbor's which he has undermined. This is often a crying injustice, and inflicts many bitter mortifications, or arouses vindictive and tiger passions. Emulation in agricultural improvement enkindles no such baleful fires. A man can make no improvements in husbandry, without at once extending the knowledge and advantage of them to others. The enlargement of the capacities of the soil and every increase of its productions, confer an immediate benefit upon the whole community.—*Selected.*

For the Southern Cultivator.

REPORT OF THE TILLAGE AND PRODUCT OF ONE ACRE OF LAND IN CORN IN 1844.

By Edmund M. Pendleton.

My land is a stiff red clay foundation, and rather a sandy soil; has been in cultivation a number of years; much worn, and never manured, in my knowledge, till the present crop, except once in the hill, with stable manure and a few loads of oak leaves to make the ground friable. It lies on the summit and slope of a hill, facing south, and of course is high and dry; a part of it was quite stony withal. Gathered a crop of wheat and hay from it last year, and plowed in the stubble with a turning plow in November; hauled out about sixty-five two-horse loads stable manure with scrapings of farm-yard, hog-pen, &c., in February; a part fermented and a part not; spread over the ground broadcast and plowed in with a turning plow and subsoiled immediately. Planted corn 3d March, three by two and a half feet, three grains in a hill, and a small handful of cotton seed put on the corn, and covered with the plow. Hoed as soon as up, and thinned to one stalk in the hill; then plowed with a colter as deep as possible. Had a bad stand and replanted early in April, subsequently added a little cotton seed to the feeble stalks; gave it three more hoeings, but no plowing. Gathered fodder the last of July, and pulled the corn late in August, which was fully ripe.

The land was measured by Tuttle H. Audas, and the corn by Henry Rogers, Esq., which amounted to fifty-three bushels and three pecks. Had it been cultivated as ordinarily and without manure, it could not have produced, in my opinion, exceeding ten or twelve bushels; so that I have nearly or quite quintupled the production of my acre.

As I paid out no money for manure except for cotton seed, I value it according to the amount of labor expended in procuring it. At this rate, the manure and hire of hand and horse in the cultivation of the acre and gathering the crop, amounted to twenty four dollars. The value of the corn, fodder and tops, at spring prices, would amount to about thirty-four dollars---making a nett profit, on one acre, of ten dollars, and the land permanently improved for years.

Sparta, December 26, 1844.

Large Yield of Cotton.--On the first of September, we received a letter from A. M. Cliett, of Houston county, in which he stated that from one acre of land, planted and cultivated, in part, on the plan of Dr. Cloud, he had gathered in the month of August, 1028 pounds of nice seed cotton, and that the stocks were bending under the weight of the unmatured bolls. Mr. C. promised to furnish us at a subsequent time with a more detailed account of the culture, &c., and the yield. We hope he will not omit to do so, when we shall take pleasure in laying them before our readers.---*Southern Cultivator, Nov.* 27.

Mr. Editor:---As I promised you I should give a fuller account of my improved lot of cotton, and as I am now done gathering it, I here will give you a precise account of the planting, manuring and the working, as well as the yield, which was injured by the drought and early frost; but according to the price, I made a sufficiency.

I live in the pine woods, on the top of the highest hill in the neighborhood, and mine is thought to be poor land, in which opinion I agree. It is mixed with black-jack, and some red-oak and white-oak runners. On the top of this hill I planted my cotton, the Texan burr---the first I have ever seen myself; but I see others have it. Last year my two acres were planted in potatoes, sugar cane, and a part in cotton, except about one-fourth of an acre, which I cleared this year, and planted in cotton to get as much as two acres square. I ran it off, or laid it off, four feet and a half one way, and three feet and a half the other. I ran my plow backwards and forwards until I could get it no deeper. This I did the first week in March, and at the same time, I applied my manure to it in the checks. At this time it was raining a moderate rain, sufficient to wet the manure, which I think was some advantage to it. As I put it out, I ridged up on it with a large turning plow, as fast as I could spread it, to prevent its evaporation. On the 8th of April I planted the seed by chopping small holes over the manure, and dropping five seed in a hole, and covered it with the foot. On the 29th of April, I broke up the middles with a ruter plow, and on the 1st of May I hoed it and thinned it out to three stalks. Then on the 22d May I ran round it two furrows in a row, with a sweeper. On the 1st day of June I hoed it the second time and thinned it out to two stalks, and on the 3d day of June I split out the middles with a sweep. On the 26th of the same month I ran three times in a row with the same sweep plow, and on the 29th of the same month I hoed it out by chopping out what was left behind the plow. This was the last work I gave it; for by this time, it was too large to work any more.

I suppose I dropped about one gallon of stable and hog manure in a hill. This manure was made by hauling fine straw into my lot and hog-pens, and then, after it was trampled on a short time, I banked it up, and covered it by throwing straw over it to keep off the sun.

This is the way I cultivated it. I divided the land into two parts, one acre each, to see which would beat; but there was no difference in land or cultivation. On one acre I gathered 2703 lbs. of as nice cotton as ever was picked out, and on the other I picked 2637 lbs. of equally nice. I think I lost 100 lbs. on each acre that I would have got if my patch had been farther from the houses, as everything running through it washed it very badly and trashed it.

These two acres have made me over four bales of cotton, besides 150 bushels of seed,

Yours, A. M. Cliett.

Pinetucky, Houston Co., Dec. 15, 1844.

Steam whistle.—An exchange paper states that a new application of this melodious instrument has recently been made, to wit, to give warning of the exhausted state of steam-boilers, or when the water in them has fallen to the spot "dangerous." Then, and not till then, the steam gains access to and rushes up a tube there placed and connected with a whistle, which immediately becomes the mouthpiece of the boiler, and shrieks, "I want water, or I shall burst."

FENCES.

Has it ever occurred to Southern planters to inquire into the amount of capital invested in fences, and the annual interest on that capital? Those who make the calculation will be astonished at the result. We have an extensive collection of facts connected with the subject, which we intend to use hereafter, if our readers should desire it. In the mean time, we commend to their attention the annexed article from the United States Gazette; and will only say, at present, that the Osage orange grows in Georgia with great luxuriance and beauty. But we imagine the most effective live fence for the Southern States, is to be made of the Cherokee rose.

REMARKS ON FENCING.

The gradual but ceaseless prostration of our forests, and consequent increase in the value of fencing material, have directed the attention of country residents to hedges, and other permanent guards against the inroads of cattle, and the no less frequent but more vexatious depredations of man. Those who listened to Mr. Biddle's last address before the Philadelphia Agricultural Society, must have been strongly impressed by the importance of this subject, and astonished at the almost incredible amount of capital invested in fences. Within the State of Pennsylvania alone as shown by apparently well founded data, the aggregate sum exceeds one hundred millions of dollars! Mr. Biddle said, "consider now the interest on this outlay, the wear and tear of the fence, and that the whole of it will not last more than ten or fifteen years, and you have as the annual tax upon Agriculture in Pennsylvania, a sum of ten millions of dollars. If this estimate appears too high, reduce it one half and you have still a tax of five millions." Various are the opinions that exist as to the best method of protection and the relative worth of live hedges, cedar fence, stone walls, &c. In many sections, the scarcity of stone utterly precludes the erection of such barriers, however ready we may be to award them the palm, for beyond question they are---when well put up—decidedly preferable; if it be said they are unsightly, all that is necessary to invest them with perennial verdure is the evergreen Ivy, or other creeping plants might be used—for instance the Virginia Ivy (Ampelopsis quinque folia) which is of vigorous growth, and would serve to cement the structure, adding to its strength whilst it imparted beauty. In New England the larger portion of fences are of this nature. As has been observed, all localities do not admit of their erection, and as wooden fences are alike perishable, and expensive, we should adopt the best substitute within our reach—that is live hedges. In all soils, and in all latitudes they may be grown, care being taken to select the plants best adapted to peculiar soils, and situations. In Europe—especially in Great Britain where hedges are almost exclusively used, they are formed of Hawthorn, Holly, Privet, Pyracantha, and other deciduous and evergreen shrubs, the Hawthorn being principally used for inclosing land, the others serve the double purpose of ornament and use. In many situations in this country, especially in wet or heavy land, the thorn unfortunately does not succeed: when partially elevated on banks they have been found to thrive better, but still are liable to decay. The Coxspur or New Castle thorn (Cratœgus crus-galli) which has been extensively planted is subject to canker, caused by the sting of an insect, which deposits its eggs in the joints of the branches, the whole plant ultimately becomes diseased, and gradually decays. Until recently the Washington or Virginia Thorn (Cratagus populifolia) was looked upon as a desirable kind, rapid in growth, handsome in flower and foilage, and free from canker --but an enemy has at length appeared, the leaves become blotched, the healthy circulation of the sap impeded, yellowish excrescenes form

on the branches, and death ensues—thus we have seen beautiful hedges of this plant decay and die, and so general has been the result it seems useless to plant it.

Fortunately we have within our reach a substitute for the thorn which is alike free from the disease and the attack of insects—the Maclura Aurantiaca or Osage Orange. First discovered by Hunter, and Dunbar, on the banks of the Little Missouri (and named by Nuttal in honor of our townsman the late Wm Maclure) it was not until the expedition of Lewis and Clark that we of the seaboard obtained the plant itself, from seed collected on that expedition and distributed by Mr. Jefferson. There are now several fruit bearing trees in this section. An acquaintance with it of nearly forty years, has shown that the mature wood is perfectly hardy, is of a rapid growth, and *bears the shears without the least apparent injury:* the foliage is highly ornamental, the young shoots are armed with formidable spines, the puncture of which is painful, and both leaves and shoots abound in acrid juice—hence it is never attacked by insects, or browsed by cattle; on the whole there is reason to believe it is destined to create a new era in fencing, and to prove of incalculable value to the farming interest. We have seen a hedge of it which though only planted half the time it would require to rear one of thorn, is a perfect barrier to man and beast. From a recent publication of Mr. James Gowen, we perceive he also has formed hedges of it on his beautiful estate at Mount Airy, specimens of it also exist at the Landreth Nurseries, and elsewhere in this neighborhood. If our fields were as effectually enclosed as they may be by this plant—much of the evil which attends a residence near a populous city would be avoided. Mischievous persons would be kept at bay, fruit would no longer cause vexation and annoyance, and the domestic birds which protect our crops and trees from insects, and add a charm to country life, would no longer be disturbed by cockney sports men—the latter is truly a crying evil which we re oice to see, has attracted the attention of the Agricultural Society. D——.

THE LAW OF STORMS—SCIENCE AND UTILITY.

The reader, already familiar with the events of the late extraordinary storm, will doubtless be interested with such statements as the following, from the pen of a gentleman whose name is a sufficient voucher for the accuracy of his remarks. Mr. Haskins, of Buffalo, author of a work eliciting high testimonials from competent critics in astronomy, and whose observations in various matters of literature and science, (instanced in the lately published Discourse on "Civilization anterior to Greece and Rome,") are frequently read, and read with pleasure, in the periodicals and other journals, has published the following in the Buffalo Commercial Advertiser, of which he was formerly one of the editors:

THE BAROMETER AND THE TEMPEST.

Mr. Editor:—For several years past I have been in the practice of sending to the public press of this city the unerring announcement of approaching gales, which have been furnished by the barometer. This I have not done as something new, but only in the hope that constant repetition might finally so fix the attention of our nautical people on the subject as to cause the procurement and use of the instruments by them.

The great gale, two years since, was known to be approaching, and was the subject of conversation among those who had barometers in this city, some eighteen hours before the first effects of it were visible either upon the lake or upon the shore. On that occasion the column of mercury in the instrument sunk three-fourths of an inch in the space of twelve hours. So again last week. On Friday afternoon and evening, the 19th instant, no one saw, by external indications, the approaching war of the elements. At about seven o'clock on that evening, three steamboats filled with passengers left this port for the west. A gentlemen who was passenger in one of these, in an account of the storm in your paper of Monday last, says: "When we left the harbor, the lake was scarcely ruffled, and for the first two or three hours there was every prospect of a quick and pleasant trip.—Every one was in the highest spirits, as we bowled merrily along, and no apprehensions were entertained until about eleven o'clock," &c.

Now, this account agrees perfectly with the external indications on shore. But before these boats left port, it was known, and was the subject of conversation in families on shore, where the barometer is kept, that a storm of unusual violence was very soon to burst upon us. During the nine hours ending at half past nine o'clock on that evening, the mercury in the barometer fell one entire inch; and this great change, in so short a time, was demonstration to those who understood it, not only of the nearness of the calamity, but of its awful severity.

Now, had the captains of these three steamboats known what was known on shore, and what they might just as well have known as any one else, is it to be supposed they would have left the port as they did? Of course they would not: and then why will not these, and all other nautical men, in the pursuit of their noble and daring profession, secure the advantages afforded them by the barometer?

I know it may be said that a seaman would be ridiculed to talk of danger when all is calm below, with smiling skies above. But surely men who could face the dangers and the awful responsibilities of last Saturday morning with the coolness and energy that our mariners did, can disregard the sneers of ignorance for a day. I admit that, had any one of the three steamboat captains refused to sail on Friday evening last, when the weather was so pleasant and promising in appearance, and had given as a reason that he "saw danger on the deep," he would have been both ridiculed and censured. But what would have been his position twelve hours later, when surrounded by the wreck of that storm, against the dangers of which he had warned his contemners? Ridicule would have been silenced then; while others, gathering wisdom from the example, would speedily possess themselves of the same means of knowledge that he possessed, and by which life and property are so greatly protected. R. W. Haskins.

Buffalo, October 23, 1844.

THE PYRAMIDS OF EGYPT.

The materials of which the pyramids are constructed, afford scope for long dissertation, because, independently of the science and skill requisite for their adaptation, the *distances* from which most of them were brought proves that each Monarch's sway extended all over Egypt and Lower Nubia, if not beyond; and in relation to this subject we gather the following facts from the second lecture of Mr. Gliddon's new course:

Geologically considered, Egypt is a very peculiar country, the quarries of different kinds of stones lying at great distances from each other in distinctly marked localities. If you see a piece of *basalt* on the beach of the Mediterranean, you know that there is no basaltic quarry nearer than between the 1st and 2d cataract, and when you find a block of granite at Memphis, you know that no granite exists but at the first cataract—nearer than the peninsula of Mount Sinai. Early civilization and extended dominion is indicated in these facts, and when we reflect upon them, we almost think we witness the work of transportation going on; that we see the builders, and the buildings themselves in process of erection. The blocks of Arabian limestone used in the interior of the pyramids were brought from the ancient quarries of Toorah, on the opposite side of the Nile, distant about 15 or 20 miles from such pyramid. These very quarries are vast halls as it were excavated in the living Rock, wherein entire armies might encamp, are adorned with now mutilated tables recording the age of their respective opening by different Pharaohs, and not only show the *very beds* whence the stupendous blocks of some of the pyramids were taken; but are in themselves, works as wondrous and sublime as the Memphite Pyramids! nay, at the very foot of these quarries, lie the countless tombs and sarcophagi of numbered generations of ancient quarrymen! These quarries are of intense archæological interest, because the tables in them record that stone was cut in them for Memphis, on such a day, such a month, such a year of the reign of such a king; and these kings begin from the remote times before the 16th dynasty, and, at different intervals came down through the Pharaonic period with many of the others, till we reach the Ptolemaic epoch—and end with Latin inscriptions similar to others in Egypt, attesting that "these quarries were worked" in the propitious era of our Lords and Emperors Severus and Antoninus, thus enabling us to descend almost step by step from the remote antiquity of 2200 years B. C., down to 200 years after the christian era. The hand of modern barbarism, prompted by the destructiveness of Mohammed Ali, has since 1830 done more to deface these tablets—to blow up many of these halls in sheer wantonness than has been effected by time in 4006 years!

Every atom of the hundred thousand tons of granite used in the pyramids was cut at Syene, the 1st cataract, distant 640 miles. The blocks, some of which are 40 feet long, had to be cut out of their beds with wooded wedges and copper chisels; then polished with emery till they were as smooth as looking glass, and then carried by land half a mile to the river—placed on rafts and floated down 640 miles to Memphis—brought by canals to the foot of the Lybian chain—conveyed by land over gigantic causeways from one mile to three in length to the pyramids for which they were intended, and then elevated by machinery and placed in their present position, with a skill, and a masonic precision that has confounded the most scientific European engineer with amazement! The very *basalt*-sarcophagi that once held the mummy of the Pharaohs, in the inmost recesses of these pyramidal mausolea, 8½ feet long by 3½ broad and 3 deep were all brought from Lower Nubia, from the basaltic quarries of the 2nd cataract, not nearer than 750 miles up the river! Looking into the *interior* of the pyramids, there is still much to stagger belief—to excite our admiration. In the pyramid of five steps, the upper *beams* that support the roof of the chamber are of *oak, larch,* and cedar, not one of which trees grow in *Egypt,* and establish the fact of the *timber trade* with Illyria, Asia Minor and Mount Lebanon in ages long before Abraham! In the fragments of a mummy the cloth is found to be saturated with the "Pissasphaltum"—Jew's pitch or bitumen Judiacum, compounded of vegetable pitch from the Archipelago, and of asphaltum of the Dead Sea in Palestine; we find *Gum Arabic,* that does not grow nearer than 1200 miles from the pyramids, attesting commerce with upper Nubia. The *gold leaf* came from the mines of Suakim on the Red Sea, or from remote Fazoglu. The liquor which cleansed out the body of the mummy was *Cedria* the fluid rosin of the pinus cedrus—that grows not nearer than Syria. The *spices* send us to the Indian Ocean—the aloes to Succotra—the cinnamon to Ceylon, the ancient Taprobane—and then the *arts* and *sciences* brought to bear upon the pyramids that must have arrived at pertection long before *that* day are not only themes for endless reflections, but oblige us to confess that in *chronology* we are yet children!

Among his novel and strange assertions, in relation to the science of the ancient Egyptians, Mr. Gliddon maintained that from the *very nature* of their *country,* and the vast *fossil* remains in their quarries, &c, the Egyptian priests must have been *geologists,* and referred to his "Chapters," page 49—for the remarks of the priest of Solon, "You mentioned one deluge only, whereas *many* happened"—and other evidences, that the *Egyptians* recognised in their mythology and chronology of the world *vast periods* of time, anterior to the creation of *man.*—*Boston Post.*

From the So. Ca. Temperance Advocate.

THE NORTH AND THE SOUTH.

Mr. Editor:—You will oblige me by publishing in your paper the enclosed remarks, which I made at the recent meeting of the Monticello Planters' Society, together with the postscript. This request is made principally to correct any misunderstanding (if any there should be) of what I said on that occasion.

Respectfully yours, &c.,

Nov. 12, 1844. Wm. J. Alston.

Mr. President:—It is natural that one who feels a lively interest in Agricultural pursuits when at home, should be attracted, when abroad, by whatever may be worthy of notice in the agriculture of the region through which he would pass.

Accordingly, during my travels of the past summer there was no subject, except one, which engaged more of my attention than the agriculture, and its appurtenances, of the country through which I travelled. I saw much to interest, and perhaps have gained some useful information.

I propose to give the results of my observations, rather than descriptions of what I saw.

There was no idea more impressed on my mind by all that I observed, than this—that improvement with the Northern people, is considered as a subject of more importance, than with us.

All classes seem to participate in the interest which is felt—amounting almost to enthusiasm—in regard to whatever may tend to develope the resources of their country. This was strikingly manifested at the State Agricultural exhibition of New York. There, were displayed the fruits of the industry and the inventive genius of an enlightened agricultural people—contending for prizes more honorable than those awarded for achievements in the Olympic games. There, were to be seen the greatest variety of best specimens of the agricultural products of that region—of stock of the most approved breeds---of domestic fabrics of the loom and needle---products of the dairy---models of the various implements and machinery used on a farm---a plowing match, more interesting than the feats of the Turf---and in conclusion, the largest assembly my eyes ever witnessed, under a vast canopy, listening to one of the most profound and accomplished scholars of New England, discoursing eloquently upon agriculture and its votaries.

Mr. President, I contemplated that scene—I may say that succession of scenes, with no ordinary emotions. I need not tell you I was gratified. In that section the cultivation of the soil, and the subjects connected with it, engage talents, science, capital and industry. The result is, that whatever is undertaken, is apt to be well done; and prosperity crowns their labors. The traveller seldom meets with a poor crop, or a poor specimen of stock, of any kind.

Everything evinces an enlightened husbandry. Their crops are chiefly corn, wheat, oats, and other small grain; potatoes, turneps, beets, cabbage, &c.; the grasses, clover, herd's grass, timothy, &c.

There are few of the above named crops which we may not produce with equal success, and in my opinion with less labor. Our natural advantages are superior to theirs. Our climate and soil are more favorable to the production of nearly all of the above enumerated crops, than theirs. If we cannot produce on all our soils, and in every season, as good Irish potatoes, we have our sweet potato, which is preferable, and which they cannot grow. If we cannot raise clover with equal success, we have our cow-pea, which is as good, and may be used as its substitute in improving our lands; and as food for man and brute; and, what is of far more importance, we have in addition, our cotton and our rice. We can support all kinds of stock at less expense than they. Our winters are not so severe, and as I have already stated, we may have greater supplies of food. Nevertheless they excel us. They make larger crops, raise better stock, etc. And why? It is because their system of husbandry is a more enlightened one, and they are constantly making improvements. We should therefore, to this point, direct our energies, both individually, and as a society.

In this connection I may remark, that one of their most important improvements is, in the use of the plow. There is nothing upon which the success of the agriculturist depends more, than the proper use of this implement. Of the truth of this, the Northern farmers seem to be fully aware. The best models of the plow, perhaps, in the world, are to be found in the Northern States. The most experienced and successful farmers there, I was told, will not use any but a large sized plow in preparing their lands for planting. These are drawn by at least two horses or oxen. The larger sized plow, used for breaking up land, requires four horses or oxen. Those first mentioned will turn a furrow 14 inches wide and 7 inches deep. The last mentioned would of course turn a deeper and broader furrow.

To deep and thorough pulverization before planting, as much as or more than to manuring, may be ascribed the greater abundance of their crops, in comparison with ours. This abundance supplies them with the means of supporting, in the best order, all kinds of stock.

There is nothing of value, that their farms can produce, or contribute to support, which does not receive that attention necessary to raise it to the highest degrees of perfection.

Permanency of improvement is regarded more by them than by us. Their buildings and their fences—whether of wood or of stone—are made to endure. Often times the traveller meets with well built stone houses and fences made of split rock, laid in mortar, as a mason would build it.

They know too the value of good roads. It is no uncommon thing to see one horse in a cart drawing a load, which it would require four horses in a wagon to draw over such roads as we are compelled to put up with, between Monticello and Columbia. We have to contend with no greater impediment to prosperity than the want of good roads; and there is no subject which requires the attention of the people, of Agricultural Societies and of the Legislature, more than the amelioration of the roads, and of the Road law. There is nothing better calculated to deter the enterprising stranger from settling amongst us, or to induce our worthy citizens to emigrate, than the difficulties which our roads present, in travelling, and in the transportation of produce to market.

I only repeat what has by others been remarked, when I say that the condition of the roads of a country may be viewed as an index of the degree of advancement of a people in the attainment of the comforts and refined enjoyments of civilized life. If this be true, we have ample room for improvement.

While travelling over the fine roads of the North, and beholding the beautiful and productive farms—the hills as well as the vallies clothed in living green, or golden grain, my mind would revert to the worn out fields and gullied hills of my own State, and the contrast produced feelings of sadness.

I determined in my own mind, if I should ever return home, and my life and health were spared, that I would endeavor, with renewed zeal, to change the system which had produced those saddening results. The more experience I have, and the more extended are my observations, the more deeply am I impressed with the belief, that the true interest of the Carolinian, I may say the Southern planter, is, to raise all his supplies that can be produced at home, first, and then as much more of whatever he may find profitable for market—whether it be cotton, grain, hay, stock, &c., as he may be able.

This change in our system would necessarily bring about an amelioration of our lands, as well as an increase of our incomes. We would have more time and means for making manure, and permanent improvements of every description, on our plantations. We would be enabled to enjoy more of the comforts and elegancies of life, and all our supplies would be of a better quality. This occurred to me with much force, when I beheld the comforts and even elegancies with which families at the North and the East, in moderate circumstances, were sourrounded; and when I saw the abundance and superior quality of almost everything necessary to supply a good table. I shall rejoice to see the day, when we all can supply ourselves with as good food and raiment as we ever purchased from our brethren of the West and the North. I believe we will then have more wealth—more of the real enjoyments of life—better roads—less hardships to encounter in disposing of our surplus produce—in a word, I believe we will then be a more prosperous, and happier people.

W. J. Alston.

P. S. By the above remarks, I do not wish to be understood as ascribing to the Northern people any pre-eminence of character—any superiority in a moral or intellectual point of view. I merely allude to their superior attainments, derived from an improved system of husbandry, and the general improvement of the country. My object was to show wherein we of the South may improve our condition, and enjoy all the advantages of the Northern farmer added to those of the Southern planter.

In these times—when the price of cotton is lower than it ever was known, and the prospect is that it may never be much higher—it becomes a grave question, for the consideration of the planter, and which every one must decide for himself, whether it is to his interest to continue to increase the over-production of cotton, by planting larger crops in proportion as the price falls; to enable him, by the increase of his crops, to purchase his supplies, which may be raised on his plantation; or, instead of this, to raise all his supplies, and then as much cotton or other produce for market, as he may be able.

If the latter policy indicated be pursued, it will then be to the planter's interest to adopt all available improvements in farming.

Whether the Tariff be reduced or not, no observant planter or statesman will deny, that large crops of cotton have invariably produced corresponding low prices; and *vice versa;* and that, however much a reduction of the Tariff may avail us, there is no cause which will contribute to raise the price of cotton so much as *to keep down over-production.* This will be done, either by increasing the consumption of cotton manufactures, by diminishing the aggregate of the cotton crops, or by both causes operating at the same time.

The reduction of the Tariff would to some extent, (not very great,) increase the consumption of cotton manufactures. The general use of cotton cotton bagging, instead of that disgraceful article called "Kentucky bagging," would increase the consumption at least fifty thousand bales annually. On the other hand, the general practice, by cotton planters, of raising all their supplies that can be raised on their plantations, would contribute more than anything in their power, to the curtailing of the aggregate of the cotton crops.

The effects of a diminished crop by all, would be an increase in the price of cotton, and their supplies furnished at home, at a less cost than that at which they could be purchased. W.J.A.

CORN BREAD.

Take as much corn meal as you wish to cook. scald it well, by pouring boiling water over it and stirring it thoroughly; then mix it to the consistency of batter, with milk; if it is pretty rich it won't hurt it, but mind the mixing part, that it is thoroughly done, the more the better.—Put in one egg, a teaspoonful of salæratus and a tablespoonful or more of lard. Mix the whole thoroughly together, till the ingredients are entirely incorporated through the whole; mind, I say, the mixing, the more the better. It is now to be baked as usual, about three quarters of an hour, and you will have the finest corn bread you ever ate.—*Western Farmer.*

GAMA AND BERMUDA GRASS.

With great trouble, and at some expense, I procured five acres of Gama grass, which I found neither horses nor cattle would eat, and I consider it as utterly worthless. The Bermuda grass is the best for pasture in the world. It is the doub grass of Central India, and among other things was brought to Georgia by Governor Ellis. You will find it figured and described in vol. v. of Sir William Jones's works, London, octavo edition. It was carried to the Bahamas, from Savannah, by Col. Tatnall, and I suppose found its way to Cuba with the cattle traders of that island. The Hindoos worship this grass as the best food for the sacred bull, and as being sent down from India by Brama for his use.

I speak very positively of the Bermuda grass, being the doub grass of India, and I do so because Mr. William H. Crawford, when secretary of the treasury, procured from India this grass, and the acorns of the teack tree, and sent me. I was struck (although a dry specimen) with the identity, and having Sir William Jones's work, in which this grass was figured, and my yard and lawn filled with it in flower, I compared them, and found they perfectly accorded in all points. But it requires a microscope to discover the beauties, which he (Sir William Jones) so rapturously describes, in its flowers. I do not know whether I stated that the Marquis of Hastings introduced this grass into England, but it failed, as Loudon states, from choosing an improper situation for it. It would grow well in your lands, that are warm, moist, and not flooded; the roots penetrate too deep to be destroyed in a good and warm soil. Its grazing powers exceed credibility in proper situations; nor is there any grass equal in quality for horses, cattle, or sheep. THOS. SPALDING.

Sapelo Island, Geo., Sept. 21, 1844.

In addition to the above from Mr. Spalding, we have had a communication for some time on hand from Mr. Affleck of Mississippi, who also forwarded us specimens of the Bermuda grass. We also recollect seeing it growing on his lawn and in other parts of the South. He says:

I find by actual experiment, weighing the Bermuda grass newly cut, and the same when dry, that it loses exactly 50 per cent., or 100 lbs. of grass make 50 lbs. of perfectly dry hay. It is the hardest grass to cut, however, that I have ever seen tried, and the easiest cured. I house all at night, which has been cut at noon. It would not, in my opinion, bear the cold of your winters—the first frost kills it to the ground. The Muskete, or as Kendall calls it, *Mesquit* grass, I presume would suit your climate better. It is yet a mooted question whether the Bermuda ripens its seed in this latitude. I will examine it carefully this season, and if I find matured seed, will send you some. I know not where *Mesquit* grass can be obtained. I send you three samples of Bermuda—one of long grass, of upright growth from the meadow, just coming in blossom—the other from an upland pasture—and the third, a stalk that I pulled off the surface of the ground, to show you how it spread, and how admirably it is adapted for embankments. On a piece of good meadow land, this grass stands in a solid mat—so close are the stalks, and so thickly interwoven are the leaves, that when cut with the scythe it very frequently stands erect. I feel very confident that it is *the most highly nutritious grass known to us.* From the specimens I send you, you will readily understand how such enormous crops of hay are cut from meadows of this sort—observe the great solidity and weight of the stem. In curing, it loses less weight than any grass I ever saw—and affords three cuttings, yielding an aggregate of from five to eight tons of hay, from a moderately good meadow.

I have said enough, however, to convince any planter who wishes to form pastures for his almost starved stock, or to do away with the necessity of pulling fodder, work so destructive to the health of his negroes, that he ought at least to make the experiment. And as a proof that I am willing to aid in spreading this treasure over the naked hills of the south, I will willingly forward to any planter, *who is a subscriber to two agricultural journals, one of which is published in the state in which he resides,* on his applying to me *post-paid,* a barrel of roots of this grass, which would, in one season, cover a large extent of ground. To the river planter it is absolutely invaluable—there is not a levee on the banks of the Mississippi could resist, for one hour, the pressure and attrition of the fearful flood now rolling along, but for their being bound together by this grass.

AGRICULTURAL EDUCATION.

Mr. John P. Norton, now travelling in Europe, gives in the Albany Cultivator the following very interesting and encouraging account of experiments in agricultural education. Speaking of the show of the Highland Society, held at Glasgow, and meetings incidental to the occasion, he says:—

"First, I would notice an Education meeting. Arrangements had been made by which five boys, from the Lanne Agricultural School near Belfast, in Ireland, were present, with their teacher, Dr. Fitzpatrick, from Lanne, Mr. Skilling, from Dublin, Sir Robert Bateson, from Templemoyle, and other gentlemen interested in the cause of Agricultural instruction, were also present. The boys were from 14 to 16 years old, and had been in the agricultural class two years. Prof. Johnston stated that by this meeting it was hoped that light might be thrown upon two points. 1. Is it possible to give boys instruction in agriculture, practical and scientific, that will be of use to them in after life. 2. Can this be done without interfering with other studies. These questions were both most distinctly answered in the affirmative by numerous gentlemen present, connected with agricultural schools in England and Ireland. The boys before mentioned were finally placed upon the platform, and with a view to answering the second inquiry were questioned in geography, grammar and arithmetic, by Mr. Gibson, inspector of schools. The examination was a somewhat severe one, especially upon grammar and geography, yet notwithstanding the embarrassments and novelty of their situation, they appeared admirably. I think that some one of them answered every question. They were then examined upon various points in chemistry connected with agriculture, by Prof. Johnston, and lastly, upon practical farming, by various other gentlemen. Their answers showed not only that they had learned by memory, but that they had also reflected. Frequent and irrepressible bursts of applause interrupted the examination, and the most sceptical were convinced. These boys devote one hour of each day to scientific and practical agriculture, and once in the week they are questioned upon the studies of the preceding five days. An enthusiasm was aroused by this exhibition which will hardly expend itself in mere words. A resolution was passed "that t was the opinion of the meeting that agricultural instruction should be introduced into the schools of Scotland." A large committee of influential and distinguished gentlemen was appointed to deliberately consider the subject. I may here mention that Mr. Skilling, superintendant and teacher in the Normal farm school, near Dublin, gave most ample testimony in favor of Prof. Johnston's works. They are introduced into all the Irish schools, and their importance impressed upon every teacher. The Catechism was written expressly for schools, and has been found of signal benefit."

UNPRODUCTIVE LAND.—How many are there who own from 300 to 500, and more, acres of land, of which one-third, or at least one-sixth part lies totally unproductive in useless brushwood, in uncleared swamps, or in land rendered worse than profitless, for want of proper draining? the owner not seeming to remember that for every such acre not yielding something in grass, in pasturage, in tillage, or in growing timber, he should charge himself, as with so much lost or thrown into the fire or the sea. There is no mistake more common than that of supposing that the more land a man has, the greater must be his profits—forgetting that the profits arise not from the land itself, any more than from an idle mill or ship, but from the skill and manner of using it; and so indispensable is capital in the business of farming, that in general it may be laid down as an axiom, that money employed in agriculture, will yield an interest in an inverse ratio to the area to which it is applied. Thus if $100 be expended, and yield 10 per cent. on ten acres, the probability is that it would yield much more if applied to half that area.– *Skinner's Address.*

From the Boston Cultivator.

AGRICULTURAL ASSOCIATIONS.

The number of agricultural associations is increasing throughout the country, and their exhibitions are annually becoming more and more interesting, not only to farmers, but to other classes also, and they give evidence that the spirit of improvement is abroad, pervading every nation where farmers are intelligent and industrious. Every branch of husbandry, household economy, and mechanic arts, is under the benign influence of the genius of improvement.

Farmers' festivals are exciting in all classes a deeper interest in agriculture and horticulture, and more respect for those engaged in these branches of industry, which tend to diffuse a salutary influence over the whole community. Farmers will find it greatly to their advantage, both in an individual and collective capacity, to associate together, and act in unison for the accomplishment of important purposes, which cannot be effected without combination and concert of action.

There should not only be State and County Agricultural Societies, but *Farmers' Clubs* should be formed in every town in the country. In every kind of improvement, whether it be the introduction of new breeds of stock, improved implements, new varieties of grain, vegetables and fruit, new modes of culture and new crops, or the establishment of libraries and other means of improvement, a great deal more can be done, and the expense will be less; and the enterprises will be more pleasant and interesting, more lively, spirited, and successful, and the effect be far more powerful on the public, by associated action among those in a town or neighborhood, who have a sameness of principles and purposes, even if their number be small, not exceeding half a dozen, provided they be zealous, discriminating, and persevering.

Then, farmers, form associations in every section of the country, and devise means to improve your condition in every department in which you are engaged, and you will learn that by intellectual labor you will save much labor of the hands, and you will be expanding your minds, and opening new sources of rational pleasure, and as you improve in your profession, you will respect it more, and command the respect of others; you will elevate yourselves in society to that important rank to which your calling justly entitles you.

In connection with this subject, numerous others are presented, and some important movements are necessary for the accomplishment of desirable objects:—and this must be done by associated and general concert. Among the subjects that claim attention, are Agricultural Education—a Little Legislation for Farmers, (as they form three-fourths of the population,) not all for other classes—Encouragement to Great Enterprizes in Agriculture, (which individuals cannot accomplish,) as well as splendid schemes for other branches of industry—a Share in the Councils of the Nation, and Important Offices, by honest, sensible, and enlightened Farmers and Mechanics, as well as a place in the Front Rank of Battle in the hour of danger.

From the Albany Cultivator.

VEGETABLE NUTRITION.

The writer scarcely expects to be able to offer any new views to those who have studied the subject thoroughly. His object is to endeavor to explain the subject to the understanding of practical men,—the farmers and gardners, those who work the soil and derive their sustenance from it. Generally speaking, *all tillers* of the soil know that if they apply a load of horse stable manure to a certain quantity of land, the product will be increased by it to a certain extent; but they do not know the minute principles on which it acts. We all know that when we eat our dinners, our hunger is satisfied, but how many of us know the true cause of that hunger and the mode or true cause of its satisfaction? It is precisely the same with plants as with animals, including men. If we do not get enough to eat, we languish, and ultimately perish; if plants do not get enough to *eat*, they also languish and perish, or yield a stinted product. Plants and animals are enabled to grow by what they eat, and although their mode of eating, is different they both act upon the same principle, and both grow by what they feed on, and in no other way. This is vegetable and animal nutrition. The increase of a plant in size, is supplied by its nutrition, so is that of an animal—if neither have any thing to eat—if a plant have no manure, an animal no food, neither can grow, both must perish. These are plain matter of fact principles that all understand. Now a new soil—that is, a soil just cleared of the timber, possesses a quantity of nutrition from leaves and other substances that have decayed on its surface in the course of time, and hence new land is proverbial for good crops; but it is soon exhausted, and then a supply becomes necessary from some other source—just as your corn crib or meat house requires replenishing when exhausted of its contents, that your table may be supplied. This is the plain common sense reason why manure is necessary to a soil—if your meat house and corn crib require a new supply of meat and corn when their old supply is nealy or quite exhaushted, so does your soil require manure when that approaches exhaustion.

But how does manure act in soil, is a question most frequently asked, and the answer is, it acts precisely as does the meat in the meat house, and corn in the crib. Plants eat as well as men. If you have no provender for your cattle, you do not expect them to thrive; if you have but a scanty supply of poor straw, you do not expect your cows and oxen and horses and sheep to get fat on that alone; so, if you have no manure of any kind to apply to your land, you do not expect large crops of wheat, or corn or rye. These you will say are all common place remarks—every body knows all this very well. The object of bringing all this common place matter before you, is merely to lay the foundation, as it were of the building. You all admit that food is as necessary to plants as to animals. The next question is, how do they take it, and how appropriate it to the supply of their necessities? We do not *see them* take it by the mouthful and masticate it, and swallow it; but it does not follow that they do not do this because we do not *see* them do it. There are at the ends of the roots of all plants, small, extremely small mouths through which they take food. Those little, extremely fine hairy roots, have small openings by which they take from the soil such matter as is nutricious. This matter is dissolved by water in the soil, and thus rendered fit to be taken up by the roots of the plants. That is, the nutritious principles that may be in the soil are dissolved by and combined in water. They in this medium enter into the sap vessels of the plants; just as do the nutricious principles taken into the stomach of animals, enter into the blood. In this way they are carried up the plant to the leaves, where they are exposed to the action of the atmospheric air; as is the blood carried to the lungs in animals for the action of the air. When the sap or circulation of the plant has had sufficient exposure to the action of the air, through the medium of the leaves, it commences its return downwards towards the roots, supplying in its way such parts of the plant as need renovation or addition of woody fibre, &c., and when such quantity as is needed has been thus taken by the various parts of the plant, the balance, if there be any, and that which has been rejected as innutritious, is voided in the form of excrement, by the roots, as is done by animals.

We now come to consider the form or nature of the nutritious principles taken from the earth. All the different constituents of nutrition are in the soil and mixed together mechanically or chemically. They are dissolved and held in solution by water. The roots of plants absorb this solution in such quantity as may be required by the plant, and it passes into the plant through the channels formed for the purpose called sap vessels, analogous to veins in animals, and immediately ascends to the leaves, where it receives the necessary supply of carbonic acid gas; I suppose it receives in addition to carbonic and gas, nitrogen; that is, that it is nitrogenized as well as carbonized, just as is the blood of animals oxygenized. It then returns towards the roots, through another set of vessels, analogous to arteries in animals, and as before remarked, supplies each part of the plant with the necessary material to restore its waste or aid in its growth. In this process, the plant does not take up crude matter, charcoal or lime, or potash, but the elements or gases that are found in the sap, and that constitute these and other portions of the plant. This whole process is precisely the same as that through which the nutrition of men and animals is carried. Now if we apply common salt to a piece of ground, we must not understand that the plants growing on it will take up salt in substance. If they take up any thing at all, it will be the elements that constitute salt, or those formed by the combination of those elements with such suitable materials as may be found in the soil. And so with other articles. Suppose we apply potash to the soil, in the form of ashes or otherwise, if there be silicic acid in the soil, then silicate of potash will be found mingled in the sap of the plant, from which the plant will obtain that glossy coating which we see on the outside of straw, cane, &c. If there be no silicic acid in the soil, and there be potash there already, then it is obvious that silicic acid, not potash, is to be added. So with all other constituents of plants. It is perfectly impossible for a plant to take from the soil any organized substances, woody fibre, potash, &c., but it must take the elements of such in solution, and form and appropriate them by means of its own organs, just as animals do. Hogs do not take their *pork* and *bristles* from the corn they feed on, but they make them from the elementary principles they obtain from the corn and atmosphere. We hear people talk of *sour soils;* there can be no such thing as a sour soil, *as such* or *per se*. Some vegetables grow on any and all soils; and if nothing else grows there, it does not follow that the soil is *sour*, but simply that there are none or not enough of the elements of other plants to supply their growth. For example, starch is composed of carbon, oxygen, and hydrogen; and sugar is composed of the same elements, only in slightly different proportions. Now oxalic acid, (the acid of sorrel,) is composed of carbon and oxygen, and these elements must necessarily exist in all soils; add hydrogen, which will certainly be supplied by rain water in abundance in all soil, and you will have the elements of starch and sugar, as well as those of oxalic acid. But you may add potash to what is called a sour soil, or lime, or soda, and still sorrel will grow there; because each plant takes from the soil and from the atmosphere, that which it requires to constitute its substances, and nothing else. You may make the most perfectly rich soil that ever lay *out of doors*, and plant sorrel or the oxalic, in it, and you will find that they will thrive equally with all other plants; just as all varieties of animals, thrive; horses, hogs, sheep and birds, on the same farm, each one taking that sort of food that suits it. The great mistake, and that which has caused much loss to farmers, is the supposition that plants convert compound or combined substances as such, into nutrition. The fact is, that all substances that afford food for plants are reduced to their original elements in gaseous or watery form, or in both, mixed. Water affords in itself a valuable source of nutrition to plants. It contains hydrogen, and there are few portions of the plant that do not want hydrogen; it contains oxygen, and there is not a single part or portion of the plant, (let it be what plant it may,) that does not contain oxygen. Water is besides, in plants as well as animals, a solvent for the other elements of nutrition. The blood in animals, cannot exist without it; or if it can exist, it cannot circulate to the advantage of the animal; just so with the saps of plants. Water not only affords as it were a vehicle for the conveyance of nutrition to the various parts of plants and animals, but also a considerable and indispensable portion of the nutrition itself.

As an illustration of these principles of nutrition, a well known fact in horticulture may be mentioned. If the fore-part of summer, after the tree has shed its blossoms, you *ring* the limb of an apple tree, that is, take off the bark for a quarter of an inch around the limb, near the trunk of the tree; or, which answers equally well, place a small wire around the limb near the trunk, drawing it tightly so that it shall be made to sink in the bark all around; you will find the limb will increase in size above the ring, but not below it; and the fruit, if it bear fruit, will be larger and ripen sooner on that limb than that on any of the others. The reason is, that the ring has intercepted the descent of the nutricious sap from the leaves at the top, and thus compelled its conversion to the growth of the limb and the fruit above the ring.

The conclusions to be drawn from the principles above laid down are obvious. 1st. Plants take nourishment precisely as animals do, except the apparatus, (the mouth) and mode of taking it, differ in form. Plants as well as animals, reduce all substances that contain nutricious principles to their original elements, before they convert any portion of them to their own organism. Therefore, when we apply stable manure to soil, we do so merely to enable the soil and the plants to extract from it the nitrogen, &c. that its ammonia, contains. The plants do not take up ammonia, but simply one of its elements, nitrogen. The elementary principles of the manure are all in like manner taken up and combined. If there be an excess of any one element, that excess is excluded from the sap; and if the sap contains an excess of any principle, that excess is ejected in the form of excrement. Indeed this paper may be appropriately concluded with the remark that *life is supported by death.* Death must take place in *something*, before *anything* can receive nutritive matter; because it is from the death and dissolution of one thing, that the nourishment of another is obtained. If animals and plants do not die, man cannot live or be supplied with meat and bread; and if animals and plants do not perish, plants cannot live. From the dissolution of one body, animal or vegetable, another body derives the elements of its own growth, its woody fibre, sugar, &c.; its flesh, bone, &c.—But every thing must be reduced to its original elements, before its constituent principles can be appropriated to other forms. In fact, all processes of life, in both kingdoms, animal and vegetable, and the mineral too indeed, are nothing more than the changing of places of the elements of organization. An animal dies, its body *decays*, as we call it. But this body does not decay. The elementary principles of which it is composed, merely *separate*, and form new combinations—one portion enters into and becomes a portion of a plant, probably a rose or a lilly, probably of a skunk; just so with a plant. A portion of its constituent principles becomes absolutely a part and portion of the body of Queen Victoria, or of that of a goose, or of that of any other animal. But let us stop. The IDEA in-

tended to be conveyed in this paper, must by this time have become obvious—vegetable nutrition is the same thing, neither more nor less than animal nutrition; governed by the same laws, resulting in the same effects, requiring the same provision. GIDEON B. SMITH.

HINTS FOR TRANSPLANTING.

1. Many persons plant a tree as they would a post. The novice in planting must consider that a tree is a living, nicely organized production, as certainly affected by good treatment as an animal. Many an orchard of trees, rudely thrust into the ground, struggles half a dozen years against the adverse condition before it recovers.

2. In planting an orchard, let the ground be made mellow by repeated plowing. For a tree of moderate size, the hole should be dug three feet in diameter, and twelve to twenty inches deep. Turn over the soil several times, and if not rich, mix thoroughly with it some compost, or well rotted manure. In every instance the hole must be large enough to admit all the roots easily, without bending. Shorten and pare monthly, with a knife, any bruised or broken roots. Hold the tree upright, while another person, making the earth fine, gradually distributes it among the roots. Shake the tree gently while this filling is going on. The secret lies in carefully filling in the mould, so that every root, and even the smallest fibre, may meet the soil; and to secure this, let the operator with his hand spread out the small roots, and fill in the earth nicely around every one. Nine-tenths of the deaths by transplanting arise from the hollows left among the roots of the trees by a rapid and careless mode of shovelling the earth among the roots.

3. When the hole is two-thirds filled, pour in a pail or two of water. This will settle the soil and fill up any little vacuities that may remain. Wait until the water has sunk away, and then fill up the hole, pressing the earth moderately around the trees with the foot. The moist earth, being covered by the loose surface soil, will retain its humidity for a long time. Indeed we rarely find it necessary to water again after planting in this way, and a little muck or litter placed around the tree, upon the newly moved soil, will render it quite unnecessary. Frequent surface watering is highly injurious, as it causes the top of the soil to bake so hard as to prevent the access of air and light, both of which, in a certain degree, are absolutely necessary.

4. Avoid the prevalent error (so common and so fatal in this country) of planting your trees too deep. They should not be planted more than inch deeper than they stood before. If they are likely to be thrown out by the frost the first winter, heap a little mound about the stem, to be removed again in the spring.

5. If your soil is positively bad, remove it from the holes, and substitute a cartload or two of good garden mould. Do not forget that plants must have *food*. Five times the common growth may be realized by preparing holes six feet in diameter, and twice the usual depth, enriching and improving the soil by the plentiful addition of good compost. Young trees cannot be expected to thrive well in sod land. When a young orchard must be kept in grass, a circle should be kept dug around each tree. But cultivation of the land will cause the trees to advance more rapidly in five years than they will in ten, when it is allowed to remain in grass.

ORCHARDS.—If your trees have moss on them, or their bark is rough, scrape them in the spring; but whether they are so or not, take a mixture of equal parts of soft soap and sulphur, and paint the trunks from the roots as far upwards as you can well reach. This will destroy the insect embryo, and preserve your trees from the girdling of mice and rats. And to destroy the worms or embryo which may be in the ground, dig the earth from around the roots of the trees, for a few feet, and to the depth of a few inches, and submit the earth thus up, to the operation of fire; when cool, mix with it a gallon of lime to each tree, and replace it. If you doubt the efficacy of this treatment, try it on a few trees this fall, and we will bet you a peck of "Ladies' Blushes" that you'll subject every fruit tree on your farm to the same operation next fall.—*Amer. Farmer.*

From the Albany Cultivator.

BUDDING.

Budding is always to be performed when the bark peals freely, which takes place when the stocks are in a rapidly growing state. Cherries and plums should always be budded by the middle of summer; apples and pears often continue growing rapidly a month later, and peaches may be done even as late as the commencement of autumn.

It is indispensable to successful budding, that the stock be thrifty, and the shoot in which the bud is inserted not more than a year or two old. No skill can succeed in old or stunted stocks for the *cambium* or mucilaginous substance between the bark and wood, which hardens into the new wood, and which cements the bud to the stock, exists only in sufficient quantities for this purpose in fast growing branches.

Every bud is an embryo plant, and the object is to transfer this from one tree to another. To effect this, it is only necessary that the bud be cut smoothly from the shoot with a very small portion of wood with it, and inserted under the raised bark of the stock in close contact with the cambium. Provided the stock is thrifty and growing, the bud smoothly cut off, and closely and evenly applied to the stock, the cambium uninjured by removing the barks and the bud be kept to its place a few days by a ligature of moderate pressure; it is of little consequence how the operation is performed and there can be little danger of failure.

The common way of cutting the bark to remove it, is to make a transverse cut and longitudinal slit, just through it, like the letter T. The bud is then slid downwards, under the bark, in the middle of the slit. The whole operation should be performed with as little delay as possible.

Whatever mode is adopted, the bark should always be lifted by placing the knife at the edge, and not by running it under, as this always injures the cambium.

After the bud is inserted, the whole should be covered, except the bud itself, with a ligature of moistened bass, corn-husk, tow, or other soft substance, bound round it with just sufficient force to press the bud closely on the stock.

In about two weeks, or as soon as the ligature begins to cut into the stock, it must be removed. Early the following spring, the stock is to be cut off a quarter of an inch above the bud, and in a direction sloping towards it, and all the branches and other buds carefully removed that the whole nourishment may go to its growth. Sometimes, as in the apricot, it is best to leave two or three inches of the stock above the bud, to tie the young shoot so that it be not broken down by the wind.

Disappointment very often arises in budding the peach and apricot, from the buds, though well set, being winter killed. This may be generally avoided by observing on the trees whence the buds are taken, on what part of the shoots the buds have withstood the preceding winter, and selecting accordingly. These will commonly be found to be the earliest formed buds on the thriftiest shoots.

Shoots cut for budding should always have the leaves removed as soon as they are taken from the tree, about a quarter of an inch above the bud. They may then, if needed, be preserved several days in damp moss or cloth.

"*Go it while you're Young.*"---The Ouachita Courier announces the marriage, in that parish, of a gentleman 91 years of age to a lady of 54. The descendants of the bridegroom---children, grand children, and great grand children---number no less than 150 souls.

From the Buffalo Commercial Advertiser.

WHEAT CULTURE.

The past season has been marked by some important developments in the culture of wheat.

Dr. Noble, of Delaware, has been reclaiming a worn-out farm for several years by the use of street manure obtained from Philadelphia, and particularly with the view of growing this great staple. Having brought the soil to a pretty fair state of fertility, he has tried the relative advantages of planting wheat in drills, nine inches apart, and sowing it broad cast in the usual way. The soil and treatment in other respects were precisely alike. The result was 34 bushels on the sown land and 42 in the drilled. These experiments were made on fields of some acres.

The soil from which this crop was harvested, a few years since would not bear over 6 to 8 bushels per acre. By planting the kernels just 6 inches a part each way, and feeding the plant on food containing, in a soluble state, all the elements necessary to build up the entire system, including the materials to form the straw, as well as the berry, a gentleman in England has grown at the rate of 320 bushels per acre!

Mr. James Campbell, of Scotland, has tried several interesting and successful experiments in the way of soaking seed wheat, barley and oats with a saturated solution of neutral salts, containing as nearly as practicable the precise elements found in the grain. The object of this was to secure to the young plant a double supply of its appropriate nourishment. The effect has been a large increase in the crop, at a very trifling expense.

Other experiments have been tried in France, with a view to determine what portion of the *organic* as well as mineral elements found in cultivated plants, is derived from the soil in which they grow, and what from the atmosphere. This is an important inquiry, and one that should be prosecuted in this country. The people of this State have paid something more than $300,000 for a geological survey of its territory. A tithe of that sum judiciously expended to diffuse among all our rural population a knowledge of the science of agriculture, would confer a tenfold greater benefit on the community at large. Breadstuffs and provisions must be produced with as little labor in New York as out of it, or farming will be a very losing business in the Empire State

The manufacture of human food, like the fabrication of clothing, will soon be profitable to those only that combine the greatest skill and knowledge with manual toil. If a farmer will not study the laws of nature which govern the transformation of certain elements of earth, air and water into corn, oats and potatoes; and the farther changes of these vegetables into pork, beef, milk and wool, his hard labor will be of little worth.

An Ancient Relic.---A correspondent of the N. Y. Commercial Advertiser, writing from Scarborough, England, states that the museum in that place contains a perfect skeleton of an ancient Briton, dug from a neighboring burrow or tumulus, six or eight years ago. The skeleton is perfect. It was enclosed in a rude coffin, the trunk of an oak tree of vast dimensions, roughly hollowed out. The tannin of the oak had so preserved the body that considerable portions of the hair were still cleaving to the scalp, although from various coins, implements and weapons of war, &c., found in the coffin, it was indisputably proved that the body must have been interred at least two thousand years. The action of the tannin had also turned the skeleton perfectly black. The proportions of this curious relic did not justify the common opinion as to the gigantic stature and muscular frames of the early Britons. The height did not exceed five feet ten or eleven inches, and the bones generally were not above the ordinary size. The only indication of muscular power was in the amplitude of the chest, and the perfect curve of the ribs.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued on the first of every Month.

TERMS.

1 copy one year..... $ 1 00
6 copies " " 5 00
25 " " " 20 00
100 " " " 75 00

The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS MUST BE POST PAID and addressed to JAMES CAMAK, Esq., Athens, Georgia.

☞ *All subscriptions to commence with the volume.*

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., FEBRUARY 1, 1845. No. 2.

HEMP CULTURE.

The following essay on the culture of Hemp was originally published in the Western Agriculturist. It is a complete treatise on the best manner of raising and preparing an article, which always commands cash sufficient to reward liberally the cultivator who proceeds correctly in obtaining this valuable product. The author of the essay is not less favorably known as a statesman than as a practical and scientific agriculturist, and the signature of HENRY CLAY will give it that weight and currency with American farmers which is due to its intrinsic excellence.

CULTURE AND PREPARATION OP HEMP.

BY THE HON. HENRY CLAY.

SIR:—Having promised you some account of the method of cultivating and preparing hemp in this state, I now proceed to redeem it. I shall endeavor to describe the general practice of the cultivators, without noticing all the deviations of particular individuals.

The district of country in which the plant is most extensively cultivated, is the Elkhorn region around and near Lexington, which derives its name from a stream discharging itself into the Kentucky river, whose branches are supposed to resemble the horns of the elk. It is also produced in considerable quantities in the counties of Jefferson, Shelby, Mercer, Madison, Clarke, Bourbon, and Mason. The soil of that region is a rich, deep, vegetable loam, free from sand and with but little grit. It lies on a bed of clay, interspersed with small fragments of iron ore, and this clay in its turn reposes on a mass of limestone lying many feet in depth in horizontal strata. The surface of the country is generally undulating. The rich land (and there is but little that is not rich) in this whole region is well adapted to the growth of hemp, where it has not been too much exhausted by injurious tillage. The lands which produce it best are those which are fresh, or which have lain some time in grass or clover. Manuring is not yet much practised. Clover is used in lieu of it. Lands which remain in clover four or five years without being too constantly and closely grazed, recover their virgin fertility. The character of the soil in the other counties above mentioned does not vary materially from that in the Elkhorn district.

The preparation of the ground for sowing the seed is by the plow and horses, until the clods are sufficiently pulverized or dissolved, and the surface of the field is rendered even and smooth. It should be as carefully prepared as if it were for flax. This most important point, too often neglected, cannot be attended to too much. Scarcely any other crop better rewards diligence and careful husbandry. Fall or winter plowing is practised with advantage; it is indispensable in old meadows, or old pasture grounds, intended for producing hemp.

Plants for seed are ordinarily reared in a place distinct from that in which they are cultivated for the lint. In this respect, the usage is different from that which is understood to prevail in Europe. The seeds which are intended to reproduce seeds for the crop next year, are sowed in drills about four feet apart. When they are grown sufficiently to distinguish between the male and female stalks, the former are pulled and thrown away, and the latter are thinned, leaving the stalks separated seven or eight inches from each other. This operation is usually performed in the blooming season, when the sexual character of the plants is easily discernible; the male alone blossoming, and, when agitated, throwing off farina, a yellow dust or flour, which falls and colors the ground, or any other object that comes in contact with it. A few of the male plants had better be left, scattered through the drill, until the farina is completely discharged, for an obvious reason. Between the drills a plow is run sufficiently often to keep the ground free from weeds and grass; and between the stalks in each drill the hoe is employed for the same object. The seed plants are generally cut after the first smart frost, between the 25th September and the middle of October, and carried to a barn or stack-yard, where the seeds are easily detached by the common flail. They should be gathered after a slight, but before a severe frost; and, as they fall out very easily, it is advisable to haul the plants on a sled, and, if convenient, when they are wet. If transported on a cart or wagon, a sheet should be spread to catch the seed as they shatter out. After the seeds are separated, the stalks which bore them being too large, coarse, and harsh, to produce lint, are usually thrown away; they may be profitably employed in making charcoal for the use of powder-mills. In Europe, where the male and female plants are promiscuously grown together in the same field, both for seeds and for lint, the male stalks are first gathered, and the female suffered to remain growing until the seeds are ripe, when they are also gathered; the seeds secured and lint obtained, after the rotting, from both descriptions.

After the seeds are threshed out, it is advisable to spread them on the floor, to cure properly and prevent their rotting, before they are finally put away for use the next spring. Seeds are not generally used unless they were secured the fall previous to their being sown, as it is believed they will not vegetate if older; but it has been ascertained that when they are properly cured and kept dry, they will come up after the first year. It is important to prevent them from heating, which destroys the vegetating property, and for that purpose they should be thinly spread on a sheltered floor.

The seeds, whether to produce seeds only, or the lint, are sowed about the same time. Opinions vary as to the best period. It depends a good deal upon the season. The plant is very tender when it first shoots up, and is affected by frost. Some have sowed as early as the first of April; but it is generally agreed, that all the month of May, and about the 10th of it especially, is the most favorable time. An experienced and successful hemp grower, in the neighborhood of Lexington, being asked the best time to sow hemp, answered, immediately before a rain. And undoubtedly it is very fortunate to have a moderate rain directly after sowing.*

When the object is to make a crop of hemp, the seeds are sown broad-cast. The usual quantity is a bushel and a half to the acre; but here again the farmers differ, some using two bushels or even two and a half. Much depends on the strength and fertility of the soil, and the care with which it has been prepared, as well as the season. To these causes may be ascribed the diversity of opinion and practice. The ground can only sustain and nourish a certain quantity of plants; and if that limit be passed, the surplus will be smothered in the growth. When the seeds are sown, they are plowed or harrowed in; plowing is best in old ground, as it avoids the injurious effect of beating rain, and the consequent baking of the earth. It would be also beneficial subsequently to roll the ground with a heavy roller.

After the seeds are sown, the labors of the cultivator are suspended, until the plants are ripe, and in a state to be gathered; everything in the intermediate time being left to the operations of nature. If the season be favorable until the plants are sufficiently high to shade the ground, (which they will do in a few weeks, at six or eight inches' height,) there is strong probability of a good crop. When they attain that height, but few articles sustain the effect of bad seasons better than hemp.

It is generally ripe and ready to be gathered about the middle of August, varing according to the time of sowing. Some sow at different periods, in order that the crop may not ripen at the same time, and that a press of labor in rearing it may be thus avoided. The maturity of the plant is determined by the evaporation of the farina, already noticed, and the leaves of the plant exhibiting a yellowish hue: it is then generally supposed to be ripe, but it is safest to wait a few days longer. Very little attentive observation will enable any one to judge when it is fully ripe. In that respect it is a very accommodating crop, for if gathered a little too soon, the lint is not materially injured, and it will wait the leisure of the farmer some ten days or a fortnight after it is entirely ripe.

Two modes of gathering the plant are practised, one by pulling them up by the roots, an easy operation with an able-bodied man, and the other by cutting them about two inches (the nearer the better) above the surface of the ground. Each mode has its partisans, and I have pursued both. From a quarter to a third of an acre is the common task of an average laborer, whether the one or the other mode is practised. The objections to pulling are, that the plants with their roots remaining connected with them, are not afterwards so easily handled in the several operations which they must undergo; that all parts of the plant do not rot equally and alike, when exposed to the dew and rain; and, finally, that before you put them to the brake, when the root should be separated from the stalk, the root drags off with it some of the lint. The objection to cutting is, that you lose two or three inches of the best part of the plant nearest the root. Pulling being the most ancient method, is most generally practised. I prefer, upon the whole, cutting; and I believe the number who prefer it is yearly increasing. When pulled, it is done with the hand, which is better for the protection of an old leather glove. The laborer catches twenty or thirty plants together, with both hands, and by a sudden jerk draws them without much difficulty. The operation of cutting is performed with a knife, of-

* Would it not be well to soak the seed in water a few hours previous to sowing? We have found this to answer nearly as good a purpose as rain after sowing, with all seeds with which we have tried it. The vegetation of mangel-wurtzel is wonderfully accelerated by it.—*Ed. Am. Farmer.*

ten made out of an old scythe, resembling a sickle, though not so long, but broader. This knife is applied much in the same way as the sickle, except that the laborer stoops more.

Whether pulled or cut, the plants are carefully laid on the ground, the evener the better, to cure; which they do in two or three days, in dry weather. A light rain falling on them whilst lying down is thought by some to be beneficial, inasmuch as the leaves, of which they should be deprived, may be easier shaken off or detached. When cured, the plants are set up in the field in which they were produced, in shocks of convenient size, the roots or butt ends resting on the ground, and the tops united above by a band made of the plants themselves. Previous to putting them up in shocks, most cultivators tie the plants in small hand bundles of such a size as that each can be conveniently held in one hand. Before the shocks are formed, the leaves of the plants should be rapidly knocked off with a rough paddle or hooked stick. Some suffer the plants to remain in these shocks until the plants are spread down to be rotted. Others, again, collect the shocks together as soon as they can command leisure, (and it is clearly best,) and form them into stacks. A few farmers permit the stacks to remain over a whole year, before the plants are exposed to be rotted. I have frequently done it with advantage, and have at this time two crops in stalks. By remaining that period in stalks, the plants go through a sweat, or some other process, that improves very much the appearance, and, I believe, the quality of the lint, and this improvement fully compensates the loss of time in bringing it to market. The lint has a soft texture and a lively hue, resembling water rotted hemp; and I once sold a box of it in the Baltimore market at the price of Russia hemp. In every other respect, the plants are treated as if they were not kept over a year.

The method of dew rotting is that which is generally practised in Kentucky. The lint so spread is not so good for many purposes, and especially for rigging and ships, as when the plants have been rotted by immersion in water, or, as it is generally termed, water rotted. The greater value, and consequently higher price, of the article prepared in the latter way, has induced more and more of our farmers every year to adopt it; and if that prejudice were subdued, which every American production unfortunately encounters when it is first introduced and comes in contact with a rival European commodity, I think it probable that in a few years we should be able to dispense altogether with foreign hemp. The obstacles which prevent the general practice of water rotting are, the want of water at the best season for the operation, which is the month of September; a repugnance to the change of an old habit; and a persuasion, which has some foundation, that handling the plants after their submersion in water during that month is injurious to health. The first and last of these obstacles would be removed by water rotting early in the winter, or in the spring. The only difference in the operation, performed at those seasons and in the month of September, would be, that the plants would have to remain longer in soak before they were sufficiently rotted.

The plants are usually spread down to be dew rotted from the middle of October to the middle of December. A farmer who has a large crop on hand puts them down at different times for his convenience in handling and dressing them. Autumnal rotting is more apt to give the lint a dark and unsightly color than winter rotting. The best ground to expose the plants upon is meadow or grass land, but they are not unfrequently spread over the same field on which they grow. The length of time they ought to remain exposed depends upon the degree of moisture and the temperature of the weather that prevail. In a very wet and warm spell five or six weeks may be long enough. Whether they have been sufficiently rotted or not is determined by experiment. A handful is taken and broken by the hand or applied to the brake, when it can be easily ascertained, by the facility with which the lint can be detached from the stalk, if it be properly rotted. If the plants remain on the ground too long, the fibres lose some of their strength, though a few days longer than necessary, in cold weather, will not do any injury. If they are taken up too soon, that is, before the lint can be easily separated from the woody part of the stalk, it is harsh, and the process of breaking is difficult and troublesome. Snow rotting, that is, when the plants, being spread out, remain long enough to rot, (which however requires a greater length of time,) bleaches the lint, improves the quality, and makes it nearly as valuable as if it had been water rotted.

After the operation of rotting is performed, the plants are again collected together, put in shocks or stacks, or, which is still better, put under a shed or some covering. When it is designed to break and dress them immediately, they are frequently set up against some neighboring fence. The best period for breaking and dressing is in the months of February and March, and the best sort of weather frosty nights and clear thawing days. The brake cannot be used advantageously in wet or moist weather. It is almost invariably used in this State out of doors and without any cover; and to assist its operation, the laborer often makes a large fire near it, which serves the double purpose of drying the plants and warming himself. It could not be used in damp weather in a house without a kiln or some other means of drying the stalks.

The brake in general use is the same hand brake which was originally introduced and has been always employed here, resembling, though longer than, the common flax brake. It is so well known as to render a particular description of it, perhaps, unnecessary. It is a rough contrivance, set upon four legs, about two and a half feet high. The brake consists of two jaws with slits on each, the lower jaw fixed and immovable, and the upper one movable, so that it may be lifted up by means of a handle inserted into a head or block at the front end of it. The lower jaw has three slats or teeth, made of tough white oak, and the upper two, arranged approaching to about two inches in front, and in such manner that the slats of the upper jaw play between those of the lower. These slats are about six or seven feet in length, six inches in depth, and about two inches in thickness in their lower edges; they are placed edgewise, rounded a little on their upper edges, which are sharper than those below. The laborer takes his stand by the side of the brake, and grasping in his left hand as many of the stalks as he can conveniently hold, with his right hand he seizes the handle in the head of the upper jaw, which he lifts, and throwing the handful of stalks between the jaws, repeatedly strikes them by lifting and throwing down the upper jaw. These successive strokes break the woody or reedy part of the stalks into small pieces or shoes, which fall off during the process. He assists their disengagement by striking the handful against a stake, or with a small wooden paddle, until the lint or bark is entirely clean, and completely separated from the woody particles.

After the above operation is performed, the hemp may be scutched, to soften it, and to strengthen the threads. That process, however, is not thought to be profitable, and is not therefore generally performed by the grower, but is left to the manufacturer, as well as that of beating and hackling it. Scutching is done by the laborer taking in his left hand a handful of the lint, and grasping it firmly, then laying the middle of it upon a semicircular notch of a perpendicular board of the scutching frame, and striking with the edge of the scutch that part of the lint which hangs down on the board. After giving it repeated strokes, he shakes the handful of lint, replaces it on a notch, and continues to strike and turn all parts of it, until it is sufficiently cleansed, and the fibres appear to be even and straight.

The usual daily task of an able-bodied hand at the brake is eighty pounds' weight; but there is a great difference not only in the state of the weather and the condition of the stalks, produced by the greater or less degree in which they have been rotted, but in the dexterity with which the brake is employed. Some hands have been known to brake from one hundred and fifty to two hundred pounds per day. The laborer ties up in one common bundle the work of one day, and in this state it is taken to market and sold. From what has been mentioned, it may be inferred, as the fact is, that the hemp of some growers is in a much better condition than that of others. When it has been carelessly handled or not sufficiently cleansed, a deduction is made from the price by the purchaser. It is chiefly bought in our villages, and manufactured into cotton bagging, bales, and other kinds of untarred cordage. The price is not uniform. The extremes have been as low as three and as high as eight dollars for the long hundred, the customary mode of selling it. The most general price during a term of many years has been from four to five dollars. At five dollars it compensates well the labor of the grower, and is considered more profitable than anything else the farmer has cultivated.

The most heavy labor in the culture of hemp is pulling or cutting it, when ripe, and breaking it when rotted. This labor can easily be performed by men. Various attempts have been made to improve the process of breaking, which is the severest work in the preparation of hemp. A newly invented machine was erected for that purpose on my farm six or eight years ago, to dress hemp by dispensing with rotting altogether, similar in structure to one which was exhibited about the same time at Columbus, during the sitting of the Ohio Legislature. It was worked by horse power, and detached the lint tolerably well, producing a very fine looking article, equalling in appearance Russia hemp. A ton of it was sold to the navy department, which was manufactured into rigging for the ship of the line the North Carolina, prior to her making a voyage of three years in the Mediterranean. Upon her return, the cordage was examined and analyzed; and although its exterior looked very well, it was found, on opening it, to be decayed and affected somewhat like the dry rot in wood. I considered the experiment decisive; and it is now considered that the process of water or dew rotting is absolutely necessary, either before or after the hemp has been to the brake. There is a sappy or glutinous property of which it should be divested, and that is the only process that has been hitherto generally and successfully employed to divest it.

An ingenious and enterprising gentleman in the neighborhood of Lexington has been, ever since the erection of the above mentioned machine, trying various experiments, by altering and improving it, to produce one more perfect, which might be beneficially employed on rotted hemp, to diminish the labors of the brake. He mentioned the other day that all of them had failed; that he had returned to the old hand brake, and that he was convinced that it answered the purpose better than any substitute with which he was acquainted. I observe Mr. H. L. Barnum has recently advertised a machine which he has constructed for breaking and dressing hemp and flax, which can be procured at the establishment of Mr. Smith, in Cincinnati. I most cordially wish him success; but the number of failures which I have witnessed, during a period of thirty years, in the attempt to supersede manual labor by the substitution of that of machines, induces me to fear that it will be long before this desideratum is attained.

The quantity of net hemp produced to the acre is from six hundred to one thousand weight, varying according to the fertility and preparation of the soil and the state of the season. It is said that the quantity which any field will produce may be anticipated by the average height of the plants throughout the field. Thus, if the plants will average eight feet in height, the acre will yield eight hundred weight of hemp; each

foot in height corresponding to a hundred weight of the lint.

Hemp exhausts the soil slowly, if at all. An old and successful cultivator told me that he had thirteen or fourteen successive crops from the same field, and that the last was the best. That was probably however owing to a concurrence of favorable circumstances. Nothing cleanses and prepares the earth better for other crops (especially for small grain or grasses) than hemp. It eradicates all weeds, and when it is taken off, leaves the field not only clean, but smooth and even.

The rich lands of Ohio, Indiana, and Illinois, are, I have no doubt, generally well adapted to the cultivation of this valuable plant; and those States enjoy some advantages for the cultivation of it which this does not possess. Their streams do not dry up as much as ours, and they consequently employ better than we can the agency of water in the preparation of it. Their projected canals, when completed, will admit of its being carried to the Atlantic capitals at less expense in the transportation than we can send it. On the other hand, the unfortunate state of slavery among us gives us, at present, probably, a more certain command of labor than those States have.

BOOK FARMING.—A FACT.

"I want to know if you believe in this book farming?" said a neighbor as he walked into the room, where I sat reading the Cultivator.

"Be sure I do," was the reply.

"Well, I don't; I never took an agricultural paper in my life. There is B. S. of W——, who came into the country fifteen years ago, and had to buy fifty acres of land on credit. He has cleared that up, and added from time to time, till he now owns two hundred acres—has good buildings, and money at interest. He always has good crops. He has averaged *twenty-five* bushels of wheat to the acre for several years; it is the same with all his other crops. While his neighbor E. W. has not raised more than *seven* bushels of wheat to the acre, and some of his other crops he never harvests. I would give more for the experience of B. S. than for all the book farming and farming by rule in the world."

"Very well, sir, now let me have a word. This 'experience' of B. S. of which you speak, (i. e. the method he adopts to raise twenty-five where his neighbor raises seven bushels of wheat, and other crops in proportion,) if written out and published, would be the very *essence* of book farming, which you so much despise, and might benefit others as well as you. And then, secondly, I know this B. S. also, and it gives me pleasure to inform you that he is a regular subscriber to, and constant reader of *three* standard agricultural papers—the Cultivator, the New Genesee Farmer, and the Western Farmer, while this same E. W. will not have an agricultural paper in his house, partly because he does not '*believe in book farming*,' and partly because he *cannot afford to take such a paper*."

Here the man suddenly remembered his errand, which was to borrow an improved harrow, a plan of which I had found in my paper, and which he was pleased to say, "did the work so much better than mine," (his)—so the subject dropped. I intend to speak to him again, ere long. H.

STATE AGRICULTURAL SOCIETY.

REPORTS SUBMITTED, NOV. 1844.

REPORT ON RICE.

The past season was one of unusual drought throughout the State. In every section, there are not wanting instances in which the wells failed.

Although the Rice crop, being irrigated by the flooding of the tides, is less dependant than any other upon the rains of the season; yet so universal and unpreecedented a drought could not fail to affect this, in common with other grain crops.

The Planters on Cooper River have suffered most severely—that river having been salt to a considerable extent throughout the season. Instead of an average production of 22,000 barrels on this river—it is believed the crop will fall short of 12,000 barrels.

South of Charleston to Savannah river inclusive, the rivers have been more or less affected with salt, and the crop will not prove to be a full one.

North of Charleston on the rivers Santee, Pee Dee, Waccamaw and Black river, the two extremes of the Rice-planting region, have been somewhat affected in production; the one by salt-water—the other by the short tides which occurred in May and June, (the months for subduing grass,) but the yield has been so generally good on the best pitch of tides, it is believed that notwithstanding the usual tribute levied in September, by the rice birds, the crop of Rice on these rivers, will be an average one.

The quality of the grain prepared thus far is good generally.

There is in some parcels, however, much of the chalky appearance, the cause of which is not accurately ascertained. It is respectfully suggested that a premium be offered for the discovery of the cause of this blemish in the grain. A premium also, for the disclosure of the cause of *rust* in Rice. The Essay in both instances to be accompanied by a detail of the remedy most successfully used during a term of years, for correction of the evil.

The "big grain rice" so favorably mentioned in the last report, has been somewhat extensively cultivated this year.

The harvest is so recently over, and so little of the general crop has been brought to market, the writer can do no better in respect of this grain than furnishing the results of his own experience for the season. With the exception of twenty-three acres, he sowed the whole of his planting in this seed, treating it in the manner usual with him, (excepting 3 acres, upon which he experimented, as will be detailed hereafter. As far as the crop has been threshed and prepared, the following are the results, as compared with the preceding year.

From field No. 7, 27 acres, less 3, (the margin not planted this year)—24 acres threshed early in October, made 1344 bushels against 27 acres, which last year made 1594 bushels. Nos. 1, 2, 3, together 45 acres, made 2116 bushels, against 2291 bushels last year. No. 10, 46 acres, 2560 bushels, against 2187.

In every instance, the Rice brought more in market, and when well cured, turned out as well under the pestle. A planter on the South side of Savannah river, who sowed some of his best land in this seed, says that it yielded in the rough 70 bushels to the acre.

The experiments alluded to above, were made with the sulphate of lime, (gypsum,) and the nitrate of potass, (saltpetre.) The tests were not complete. They will be repeated another year.

It is understood that rice has been cultivated with the plow chiefly the past season, and profitably by Mr Quash, (on inland swamp,) and others; also that the method in harvesting of *cradling* rice, has been practised by some gentlemen on Cooper river with success satisfactory to them.

All which is respectfully submitted.

Columbia, Nov. 26, '44. R. F. W. ALLSTON.

Mr. President:—I beg leave to present for the examination of the Society, over which you preside, the enclosed account of an experiment made by me the last year in a Mineral manure, as applied to the culture of the staple which I plant, and to submit the production of grain to the consideration of your Committee.

Very respectfully, R. F. W. ALLSTON.

Columbia, Nov. 25, 1844.

EXPERIMENT IN RICE.

Field No. 12, was planted 16th April, 1844, 2½ bushels of seed per acre, covered with water, and plowed until the sprout was entirely green—the water was then drawn. As soon as the plant was strong enough, it was hoed rather deep, and the low water put on deep for four days, then slacked down to about half the height of the plant; at this height the water remained until the plant acquired sufficient strength to stand upright, when the water was slacked down a little, the grass picked out, and then as soon as the turbidness of the water had sufficiently subsided, it was drawn off. Two or three days after, namely, on the 18th June, two ¼ quarter beds, (38½ feet wide,) at one end of the field, 698 feet in length, were treated with 86 lbs. of nitrate of potass, (saltpetre,) finely powdered, and sowed broadcast over the two beds. As soon as the ground was sufficiently dry, namely, about ten days from the drawing of the water, the rice was hoed deep. Afterwards, on the 10th of July, it was lightly brushed through with a hoe, and laid by, the long grass was picked out late in the season, and the rice harvested two days after the stormy rain in September, namely, the 12th.

It was threshed and winnowed on the 19th Nov., 1844, in the presence of George T. Ford, Esq., who also saw it measured, as well as the land. The production was *ninety-two bushels, three pecks and three quarts*, of clean winnowed rice, independent of the straw and flat rice.

Estimating the contents of the acre at 45,000 square feet, which is usual among planters, this product is at the rate of 78¼ bushels per acre.

R. F. W. ALLSTON.

Matonza, Pee Dee, Nov. 19, 1844.

I hereby certify that the foregoing facts, as far as the threshing, winnowing and measuring of the rice and land is concerned, are strictly true, having been done in my presence.

GEORGE T. FORD.

The foregoing facts are entirely within my own knowledge. JESSE BELFLOWERS.

Columbia, Nov. 26, 1844.

Hon. Whitemarsh B. Seabrook:—

DEAR SIR:—I send you herewith a small package containing several ears of a species of Millet, which is cultivated by many planters of Orangeburg District, as a substitute for provender for work horses and cattle, during the warm season of the year.

Many planters use no other provender from the latter part of May, until about the middle of September, and it is regarded by them as superior in most respects to the fodder of Indian corn—to oats, pea-vines, gama or rye-grass. One acre of it will feed eight horses—it should be used in a green state, and is exceedingly nutricious.

It is planted like upland cotton in rows, three feet apart, in drill or in chops nine inches apart on the bed, and in rich land may be cut every fifteen days. Cotton seed and stable manure in equal parts, make a good manure for it, and it should be worked with the plow or hoe after every cutting. I have received so much advantage from planting it, that I would be pleased to see it in general use.

I am, dear sir, with great respect,
Your ob't. serv't., D. F. JAMISON.

The enclosed statement, together with two certificates, designed to accompany a sample of fine Sea Island Cotton, is respectfully submitted to the State Agricultural Society of South Carolina, by ARCHIBALD H. SEABROOK.

Edisto Island, Nov. 18, 1844.

Gentlemen of the State Ag. Society of So. Ca.:

In offering for the premium for "the greatest production of Sea Island Cotton, having reference to quality and valuation," the undersigned begs leave to make the following statement:

The ten acres of land on which the cotton was grown is high and of a close texture. Originally strong, it has been much impoverished by injudicious cultivation and management. On eight acres, from which 5440 pounds have been gathered, 160 piled single-horse cart loads of marsh were put in, in August, 1843, immediately after being cut. These were not entirely covered, as is the usual practice, but a few hoefuls of earth were placed on them at short distances, to prevent the depredations of cattle, and some of the most valuable properties of the grass from being washed away by rain. The cotton on the remaining two acres, was not designed to be mixed with the general bulk, for as they had been assisted only with pine straw, and a few loads of salt mud, on one third of the land, there was no ground for believing that the yield, under the most favorable circumstances, would be large.

These acres, it is confidently supposed, did not together realize over 400 lbs.; thus rendering the product of the eight acres designed for the premium, in reality 5440 lbs., as already stated. In height, the plants on the latter averaged about 4½ feet, while on the former not over 3 feet. The mode of cultivation did not differ from that usually adopted by the grower. It is to the manure and the manner of applying it, that the undersigned would briefly invite the attention of the Society.

According to the customary usage, the marsh cut in July or August, is piled up and not taken to the field until after the crop has been prepared for market. At that time it will be found that the quantity has been lessened one-half, and the quality much depreciated. By the scheme adopted by the undersigned, the grass was allowed to rot on *the ground intended for cultivation.* In this way the saline and other ingredients not evaporable were preserved. By exposure too, for several months, to the combined action of air, light and moisture, the process of decomposition in the spring is regular, and the matter becomes food for the plants early in the season.

If a complete listing be given to the land in the summer, these results do not take place so soon, and when they occur, the decay is frequently so rapid, that injury to the plants, especially if the season be variable, may with certainty be looked for. The "blue disease," (among other causes,) arises from excess of nutriment, furnished by salt-grass, in a state of too high fermentation. Where the parts are allowed to be broken down, or fully prepared to yield to the power of the decomposing agents, by being thrown into heaps of any size, or partially covered in the manner already stated, the undersigned has never known or heard of any other than the most salutary effects flowing from the practice. The plan of putting the marsh on the ground intended for the crop in summer, is much preferred, for thereby nothing is lost that is in the power of the planter to save. Other decided advantages of a minor and different character, may be enumerated, to one of which only, he will now advert. It is the only practicable mode of making an allotment of work to the laborers. The task for each reaper is three piled cart loads per day, which, after being determined by the head cartman, who for this reason should be a faithful slave,) is immediately taken to the field. By this means the master is able to ascertain with great accuracy, the quantity of work of this kind which can be done by any number of men in a given time.

The undersigned would further observe, that the season, though in general favorable to the cotton crop, was too dry for high lands, and that although in other fields, naturally or artificially richer, a greater product per acre has probably been made, it is doubtful whether, looking to the anticipated yield in money, the labor of the grower will anywhere be better rewarded.

From the fineness of the staple, it requires 1500 lbs. in the seed to make 300 lbs. of clean-ginned cotton. At this rate, if the cotton commands the lowest price at which it has been valued by two distinguished factors in Charleston, (whose certificates accompany this,) the amount in money, per acre, will be, for the ten acres, $81.76 cents; or, for the eight acres, deducting 400 lbs. for the two acres unintentionally thrown in, $95.20 cents; making $761.60 cents for the eight acres. A. H. Seabrook.

—

The undersigned, factors and sellers of fine Sea Island Cotton in the Charleston market, hereby certify that they have examined and valued a sample of Sea Island Cotton, represented as the growth of the present year, and produced by A. H. Seabrook, Esq., of Edisto Island.

The sample is of beautiful and extra quality, preparation good, soft, long and very fine staple. As no cotton of the same description has thus far been sold or offered for sale in the market, they are unable to affix a value to it at this time. By comparing the specimen with similar cotton sold last season, they are decidedly of opinion that it would have commanded then, from 70 to 75 cents per lb. James O'Hear.
Wm. M. Lawton.

Charleston, S. C., Nov. 21, 1844.

—

I hereby certify that Mr. A. H. Seabrook's Cotton, called the Queen, and produced from ten acres of land, was weighed in my presence, this sixteenth day of November, 1844, and turned out five thousand eight hundred and forty (5840) pounds, gross. Wm. F. Meggett.

REPORT OF THE CAMBRIDGE AG. SOCIETY,
On the situation of Whitfield Brooks's Plantation, and its claims for the Premium to be awarded for the best managed Plantation.

At the request of Mr. Whitfield Brooks, of the District of Edgefield, we have examined his plantation with all the minuteness and accuracy, which circumstances would allow, and submit the following Report:

The land in cultivation is represented to be about 700 acres, of which one-third may be denominated swamp and second low grounds, and the remaining two-thirds, high land, under one continuous line of fence, with dividing fences at convenient distances, separating the whole into fields varying from 30 to 120 acres. The high land is in a clean condition, free from trees, logs, briars or gullies, and in a state of progressive improvement by the rotation of crops, and the application of manure. The low land has been thoroughly drained by two main ditches of large size and many smaller drains, where the condition of the land required them. Cultivation extends to the border of the ditches and branches, the latter having been straightened and cleared out, to admit the free passage of water. The land in cultivation, presents the appearance of an undulating valley, formed by the junction of several small streams, from an elevated point of which the eye commands a view of the whole area of the plantation, with the crop of cotton, corn and small grain, in their present condition. There is a raised and well made road, passing nearly through the centre of the fields, and branching off in various directions, as necessity or convenience required. Gates are erected at every cross fence, which afford an easy passage to all parts of the plantation. We saw about 200 acres in corn, 250 in cotton, from 125 to 150 acres, which had been in wheat, oats, rye and barley, and about 90 acres in wheat, rye and oats, for the fall sowing of grain, all of which is in a state of apparent gradual improvement and skilful cultivation, having yielded a good crop the present year, notwithstanding the severe drought which prevailed in this section.

We next directed our attention to his houses, fixtures and lots, of various kinds and sizes. The stable lot is of good size, well shaded and supplied with water from a well, near at hand, which is worked by a pump, and from which the water is conveyed by troughs. In this lot stands a large two story framed stable, divided on the lower story into stalls, and affording a capacious repository in the second story for fodder and oats. On each side of the stable, is a framed shed, used as a shelter for the wagons, and for the feeding of horses in summer. At the north end of the stable, another shed has been erected about 30 feet square, with a trough and rack in the centre, for the use of the mules in summer, having a large apartment above for fodder. These are substantial buildings, and well covered with shingles. Besides these, there is a line of log buildings, extending from 40 to 50 yards in length, with stalls for separate horses and oxen, and apartments for harness, having in the rear a large shed for oxen. This lot has a communication by means of gates with various other lots, as appurtenant to the stable, one of which is appropriated to oxen, another with shade trees and a stream of water, into which the stock is turned for rest or gentle exercise. The third is a grove, neatly trimmed and cleaned, which is used for various purposes, occasionally for cows and young pigs, for sheep, or for horses and mules that become either crippled or sick. His cribs are substantial and well arranged buildings, in a line with the stables, and covered with shingles. The stable lot communicates with the gin lot, in which stand two framed gin houses in a line, each thirty-two feet square, with a passage between them of 20 feet, all under one cover and well floored, the passage answering the purpose of drying cotton and small grain, or as a shelter in rainy weather for any kind of employment in such seasons. At one of the gin houses, and in connection with it, is a framed building, two stories high, in which are placed the threshing machine and fan, for cleaning of small grain. These are propelled by machinery, and principally constructed by the mechanics of the owner. In the same lot is a two story framed barn, designed for grain, the upper story of which is ceiled, and divided into bins of 30 bushels each, for the reception of grain. On each side of the barn is a framed and enclosed shed with shingle roofs, for fodder, oats, &c. Near the gin house and cotton room, stands the screw, having a framed building around it, and so constructed, that one entire side may be removed, to admit repairs of the screw.

In the rear of the gin house lot is another, (about one acre, now in small grain,) in which has been erected a row of substantial buildings, extending about two-thirds of one entire side, in which is preserved provisions for the cattle, and immediately in the rear of this line of buildings, and fronting the south, is a covered shelter for cattle in winter, with which is connected a winter lot, having trees and water, and also a large trough, made of poles or logs, to preserve the food from the feet of the cattle. In this lot the cattle are penned at night, both in winter and summer, and a supply of litter constantly applied around the trough for making manure. Much attention has been and is devoted to making manure, and the arrangements are well adapted to this purpose. We saw in the horse lot seven large and substantial made pens, filled with manure, and three more in the cow lot, containing in all at this time not less than from 400 to 500 wagon loads.

The negro houses have been erected in a shade lot, in a parallel line with the stables and corn-cribs, about 30 yards in the rear, but at a convenient distance from them, and extending to the east, and presenting a front to the south. They are either framed or hewed log buildings, with framed roofs, having double brick or rock chimnies, plank floors, and stand from 30 to 50 yards apart. In front of these buildings is a shade lot, from 3 to 4 acres, enclosing the loom house and well, and in the rear, a garden and poultry house, for each family of negroes. The house of the overseer is a framed building, with three rooms and brick chimneys; and with its appendages, occupy the crown of the hill, and commanding a view of the blacksmith and work-shops, the negro houses, stable lot and houses, the gin house, lot and buildings, and the cow lot and its appurtenances. The dwel-

ling house is a two story building, finished in a plain but comfortable style, with shed and piazza, having six rooms and a passage, and stands in a luxuriant grove of oaks about 400 yards from the overseer's house, with which it is connected by an avenue and lawn, containing from 10 to 15 acres. It has the usual appendages of a garden, kitchens, meat house, fowl house and dairy. We were also shown various arrangements for raising and taking care of stock through different stages of its growth. These consist of various lots of different sizes under good fence, and an abundant supply of water. The first is a wood enclosure of near 500 acres, partly high land, and partly swamp, and so arranged as to be easily divided by a set of bars. This is intended as a permanent enclosure for hogs, and occasionally for sheep and other stock. It has a direct communication with the stable lot, and cow lot, through a gate, by means of the lawn above referred to, and hogs are fed within 300 yards of the overseer's house, which commands a view also of this lot. Another was a lot of 75 acres, of which about one half is in woods and the other in small grain, intended for ewes and lambs and other young stock, and is connected with the lawn around the dwelling house by a gate. The third is a lot adjoining the dwelling house, containing about 15 acres, half in woods and the other in small grain, intended for calves and poultry. These are in addition to the lots above referred to, as connected with the stable lot, all of which constitute about 12 in number. There is also a shelter with stalls for the milch cows in winter, and a house for food and shelter for the calves. In short, there is a lot for all kinds of stock, adapted either to summer or winter use, with a shelter or cover for each kind. It is a rule of the establishment to put all food under cover, so that we found neither oats, fodder, straw nor shucks exposed to the weather, but all were stored away in substantial buildings. The overseer has an appropriate house or room for the tools, plows, harness and wagons, and no implement or vehicle is allowed to remain from under cover. The various lots adjacent to the stable lot and dwelling, are surrounded by good fences, neatly shrubbed trees trimmed, neat and substantial gates, and all supplied with water and shade. The stock on the plantation is as follows:—about 90 stock hogs, 15 sows, with near 100 pigs, about 90 head of horned cattle, including three yoke of oxen, milch cows and calves —about 70 head of sheep, and from 40 to 50 hogs for the slaughter pen, all in a good and thriving condition. The horse power is 16 mules, and 7 horses, of which three or four are brood mares. The overseer reported that he manufactures clothing for the negroes, both winter and summer. The supply of pork will be abundant for the wants of the plantation, amounting to 7 or 8,000 lbs. That from the sale of wheat, rye, corn, peas, and other surplus products of the plantation, he is enabled to pay the current annual expenses, except his wages, besides furnishing a supply of flour to his employer.

In conclusion, we cheerfully bear testimony that for the arrangement of the plantation, for the reclaimed and highly improved condition of the land in cultivation, for the means provided for its permanent improvement, for the substantial and convenient character of the buildings of every description, and for the general economy displayed in its government, there is manifested a skill, judgment and industry, of no ordinary character, and which was indispensable to the accomplishment of the present improved condition of the plantation. We ought not, however, to omit some notice of the utensils and vehicles used on the plantation and of the present crop. These consist of the bull tongue plow, the common shovel, the half or twisting shovel, the barsheare, of Northern construction, the sweep or scraper, and iron tooth harrows. Several of these are used in breaking up and preparing land for cultivation, and all except the barsheare, in the cultivation of the crop. There are three wagons and two ox carts, with their usual apparatus. The land seems to have been thoroughly broken up, and closely and skilfully plowed and planted, plowed and laid by in the best mode to prevent washing. We were shown a field of 50 acres of corn, planted in the drill, which averaged over 25 bushels to the acre. The product was between 1300 and 1400 bushels. Another of 70 acres, which averaged about 20 bushels, or about the same product as the first. A field of 30 acres on an elevated ridge, yielded an indifferent crop, being cut off by an unusual drought. There remains from 30 to 35 acres of corn ungathered, which will yield between 400 and 500 bushels. The crop of cotton was greatly injured by drought and rust, and will only yield 130 bales of the average weight of 350 lbs. In a seasonable year, the same land, under the same cultivation, would have yielded 175 bales. In addition to the corn and cotton, there were made 250 bushels of wheat, 50 bushels of rye, a small quantity of barley, and the average crop of oats, an abundant supply for the plantation—75 bushels of peas have been gathered and cleaned, and some 10 or 12 stacks of peas on the vine. The hogs are a cross from a Berkshire boar, and sow of the common stock. The cattle are in an state of improvement from a cross, by a three year old Durham bull, a very superior animal, bred by Col. B. F. Taylor, of Columbia. The sheep are a cross of the Bakewell breed, from an ewe and ram, a present by Major Thomas Means of Fairfield. In making this Report, our only object has been to give a full, fair and impartial account of the state of the plantation, and if we have been tedious, the only apology we can offer is, that it was inseparable from a faithful discharge of the office committed to us. In certification of which, we have signed our names, this 21st of November, 1844.

R. C. Griffin, former Treas'r. W. Andrews.

Thomas Payne. James Dorn.
J. M. Walker. Solomon Dorn.

Black Oak, Nov. 22, 1844.

To R. W. Roper, Esq.—

Dear Sir:—The short period which has elapsed since the receipt of your letter, requesting information on the subject of the Marl experiments in this neighborhood, must be my apology for so unsatisfactory a reply as this must necessarily be.

Previous to the year 1843, there had been but one instance of the application of marl as a manure to the soil, in this immediate neighborhood. Its existence was known in a few localities, where it had been thrown out from excavations through our swamps, but until the use of the auger for boring was introduced by Mr. Ruffin, its great extent and almost universal presence was not generally suspected. By his personal exertions and the use of this simple instrument, a vast mine of agricultural wealth has been unfolded, which only requires the energy and industry of the planter to be made available.

According to the experience of Mr. Ruffin and the Virginia planters, too short a time has elapsed since its application to our lands, for us yet to realize its full effects. The first experiment in marling in this section of country, was made by Mr. F. A. Porcher, in 1840, on 17 acres of land, at the rate of 100 bushels per acre. His statement is thus: Planted in cotton the first year, and did well. In 1841, rested; 1842, in cotton, with an additional manuring of 30 horse-cart loads of stable compost, a good crop —140 lbs. of ginned cotton; 1843, in potatoes and slips, but did badly; 1844, in corn, making 24 bushels per acre.

He states a second experiment of 2 acres, marled the past year and planted in potatoes. Began to use them in August; that on the marled land, the only good part of his crop. Mr. Philip M. Porcher states an experiment on 7 acres marled in 1843. Kept one acre unmarled for comparison, and treated the remaining six with marl, at the rates of 250 and 130 bushels per acre. The season of 1843 was peculiarly unfavorable, and no good effects were observed from the treatment. In 1844, (the present year,) he picked from an acre, on which 250 bushels of marl had been applied, 460 lbs.; from one on which 130 bushels had been applied, 380 lbs.; and from the acre left unmarled, 260 lbs. seed cotton. The same gentleman states another experiment on a field of 6 acres, marled in 1843, at the rate of 120 bushels per acre, applied together with stable manure and cotton seed. Planted in corn the first year, and made 20 bushels per acre. In 1844, added 100 bushels of marl per acre and other manures; the field made an average of 44 bushels of corn per acre. It should be stated that the land used in both of the above experiments, was old and exhausted from hard treatment. From these, and many other experiments in this neighborhood, it would appear that on old lands, but little effect is seen the first year after marling.

It is to be regretted that in two instances, where the most marked beneficial effects were seen from the application of marl, no accurate account of the result has been kept.

Mr. S. G. Darant the last winter, applied marl at the rate of 100 bushels per acre, to 15 acres of newly cleared pine land. A small spot of 30 or 40 feet square was left unmarled. No account of the relative production has been taken, but the unmarled spot has scarcely made any cotton, whilst a fair crop has been gathered from the other; the increase of production is rated at 4 or 5 fold, or more.

The other instance alluded to above, is an experiment by Mr. R. W. Mazyck, with green sand marl, on a few acres of cotton land. The crop has not yet been entirely harvested, but by comparison with the adjoining parts of the field unmarled, the increase must have been double at least.

At the meeting of the Black Oak Agricultural Society held last spring, it was ascertained that about 1200 acres of land, within the geographical limits of the Society, had been marled during the past year up to that period. There is no doubt that fully the same amount of marling will have been accomplished again by our next meeting in the spring.

I am, very respectfully, &c.,
H. W. Ravenel.

AGRICULTURAL PRODUCTS OF THE UNITED STATES FOR 1843.

Wheat,	100,310,856	bushels
Barley,	3,220,721	"
Oats,	145,929,966	"
Rye,	24,280,271	"
Buckwheat,	7,959,410	"
Indian Corn,	494,618,306	"
Potatoes,	105,756,133	"
Hay,	15,419,807	tons.
Flax and Hemp,	161,007	"
Tobacco,	185,731,554	pounds.
Cotton,	747,660,090	"
Rice,	89,879,145	"
Silk Cocoons,	315,965	"
Sugar,	126,400,310	"
Wine,	139,240	gallons.

The supposed value of the above, $607,185,413. The articles of wheat, barley, buckwheat, potatoes, tobacco, rice, and sugar, amounted to less in 1843 than in 1842; though the aggregate value of all the above named articles in 1843, was $24,545,445 greater than in 1842. The population of the United States in 1843 was 19,183,583.—*National Intelligencer.*

Simple Cure for Croup.—We find in the Journal of Health the following simple remedy for this dangerous disease. Those who have passed nights of almost agony at the bedside of loved children will treasure it up as an invaluable piece of information. If a child is taken with croup, instantly apply cold water, ice water if possible, suddenly and freely to the neck and chest, with a sponge. The breathing will almost instantly be relieved. So soon as possible, let the sufferer drink as much as it can; then wipe it dry, cover it up warm, and soon a quiet slumber will relieve the parent's anxiety, and lead the heart in thankfulness to the Power which has given to the pure gushing fountain such medicinal qualities.

THE MARL FORMATION.

As Geology is intimately concerned in pointing out to Agriculture the kinds of rock useful as manures, we have thought it advisable to republish in our paper an extract from a report read before the Geological Society of London, by the eminent Geologist, Mr. Lyell. He visited our State in 1841, and on his return to Europe, read before the Society, a paper, "On the Tertiary Formations and their connection with the chalk in Virginia, and other parts of the United States." We have selected from this paper what relates to South Carolina and Georgia. We would recommend to our Farmers engaged in marling, to preserve all bones and shells for scientific examination, as they are interesting to those gentlemen who are making collections for their cabinets.—*Carolina Planter.*

"ON THE TERTIARY FORMATION OF SOUTH CAROLINA AND GEORGIA."

BY CHARLES LYELL, V.-PT. G. S. L.

Charleston stands on a yellow sand, beneath which is a blue clay, containing the remains of Testacea that inhabit the adjacent seas; and Dr. Ravenel informed Mr. Lyell that he had found in it the *Gnathodon cyrenoides*, not now known to occur in a living state nearer than the Gulf of Mexico. The author could not ascertain whether the post-pliocene formation rises above high-water mark; but he states that, on the Cooper river, thirty miles north of Charleston, there occurs beneath the superficial sand and mottled clay a fresh water formation, in which Dr. Ravenel has found the remains of the Cypress, Hickory and Cedar, which must have grown in a fresh water swamp, although the formation is now six feet below the level of high water. No shells have been noticed in the deposit, but they are also commonly wanting in the marsh accumulations of that region. As the salt water of Cooper river must now cover much of this deposit, a very modern subsidence, Mr. Lyell says, must have taken place along the coast. At Dr. Ravenel's plantation in the low country, near the mouth of Cooper river, is a pulverulent limestone, artificially exposed, which Mr. Lyell thinks may be an eocene formation, though its fossils differ from those of other deposits of that epoch.

Between this point and Vance's Ferry, on the Santee river, is a continuous formation of white limestone, which Mr. Lyell examined with Dr. Ravenel at Strawberry Ferry, Mulberry Landing, the banks of the Santee canal, Wantout and Eutaw. It varies in hardness, and consists of comminuted shells; but it very rarely exhibits any laminæ of deposition, and even where it attains a thickness of twenty or thirty feet, there would be a difficulty in determining whether it were horizontal, if a bed of oysters, like that at Vance's Ferry, did not occasionally occur. At the Rock bridge near Eutaw springs, the limestone composed of comminuted shells, corals, the spines of Echini, &c., resembles so precisely the upper cretaceous formations at Timber Creek in New Jersey, that Mr. Lyell at first felt no doubt of the identity of the two formations, although the organic contents of the limestone prove that it belongs to the tertiary series. This resemblance has led to the admission into Dr. Morton's excellent work on the fossils of the cretaceous group, of the *Balanus peregrinus, Pectencalvatus, P. membranosus, Terebratula lachryma, Conusgyratus, Scutella Lyeeli*, and *Echinus infulatus**, though they do not really belong to the chalk series; and to several other similar mistakes, whereby, Mr. Lyell observes, beds of passage have been erroneously supposed to exist. Among the most widely distributed of the limestone fossils is the *Ostrea sellæformis;* and he searched in vain at various points throughout a distance of forty miles for an admixture of characteristic cretaceous and tertiary organic remains, though the chalk formation, containing Belemnites and Exogyræ, occurs between Vance's Ferry and Camden. The Santee limestone, he is of opinion, cannot be less than 120 feet thick at Strawberry Ferry, being vertically exposed to the extent of seventy feet in the banks and bottom of Cooper river, and to the height of fifty feet in the neighboring hills. Its upper surface is very irregular, and is usually covered with sand in which no shells have been found. Mr. Lyell followed the limestone north-westwardly for twelve miles by Cave Hall and Struble's Mill to near Half-way Swamp. At Stoudenmire or Stout Creek, a tributary of the Santee, it has disappeared beneath a newer tertiary deposit of considerable thickness, consisting of slaty clays and quartzose sand. No fossils were observed by him in the deposit at Aiken. A similar formation is developed at Augusta, where the Savannah divides the States of South Carolina and Georgia, and it must, in some places, be more than 200 feet thick. Three miles above the town are the rapids, which descend over highly inclined clay-slate and chlorite chist, overlaid unconformably by tertiary beds. This point is the western boundary of the supracretaceous series; and Mr. Lyell observes, that on all the great rivers of the Atlantic border from Maryland to Georgia, and still further south, the first falls or rapids are along a line at which the granitic and hypogene rocks meet the tertiary, and which is nearly parallel to the Atlantic coast, but at the distance of 100 or 150 geographical miles. This great feature, Mr. Lyell states, was first pointed out by Maclure, but he adds that portions of the tertiary formation usually cover the hypogene rocks for a certain distance above the Falls, and that their outline is very irregular and sinuous. On Race's Creek near Augusta, the highly inclined clay-slate, containing chloritic quartzose beds with subordinate strata much charged with iron, are decomposed to the depth of many yards into clays and sands which resemble so precisely a large portion of the horizontal tertiary strata of the neighboring country, that disintegrated materials might be mistaken for them, if the veins of quartz which often traverse the argillaceous beds at a considerable angle, did not continue unaltered. The only point at which Mr. Lyell saw any organic remains in beds associated with these upper tertiary red strata was at Richmond in Virginia, where he obtained casts of decidedly miocene fossils; but as he observed on the Savannah river thick beds of sandy red earth beneath the burr-stone of Stony Bluff, he concludes that the same mineral character may sometimes belong to the upper division of the eocene group. At the rocks six miles west of Augusta, the tertiary beds derived from the hypogene rocks have the appearance of granite, and have been called gneiss by some geologists. They exhibit occasionally a distinct cross-stratification, and include angular masses of pure kaolin.

Though the Savannah in its course from Augusta to the sea, flows for the greater part in a wide alluvial plain, and has a fall of less than one foot in a mile, yet Mr. Lyell descended it to obtain information, by means of the Bluffs, respecting the superposition of the several masses, natural sections being otherwise difficult to obtain. After passing cliffs of horizontal strata in which the brick-red sand and loam prevail, the first exposure of a new deposit was observed at Shell Bluff, forty miles below Augusta. The height of the section was 120 feet, and its extent more than half a mile. The lowest exposed strata consisted of white, highly calcareous sand, derived chiefly from comminuted shells, but the beds passed upwards into a solid limestone, sometimes concretionary, and containing numerous casts of shells. In one place a layer of pale green clay showed the horizontal character of the formation. The upper part of this deposit is more sandy and clayey, and incloses a bed of huge oysters, *Ostrea Georgiana*, occupying evidently the position in which they lived. The total thickness of these lower strata is eighty feet. The upper portion of the cliff is composed of forty feet of the red loam which prevails at Aiken and Augusta, and yellow sand. Mr. Lyell did not find any fossils in this deposit, but he believes that it belongs to the burr-stone formation, and therefore to be an upper eocene accumulation. At his first inspection of the casts contained in the limestone, he inferred that they belonged to eocene species, without any intermixture of cretaceous or miocene forms; but it was not till he had the advantage of Mr. Conrad's assistance that he was able to determine the following twelve species which are well known to be characteristic fossils of the eocene beds of Claiborne and Alabama:—

Oliva Alabamiensis.	Corbula nasuta.
Calyptræa trochiformis.	—— oniscus.
Dentalium alternans.	Nucula magnifica.
Venericardia planicosta	Crassatella prætexta.
Cytherea Poulsoni.	Ostrea sellæformis.
—— perovata.	—— Alabamiensis

The same shelly, white, calcareous beds, overlaid by red clay and loam, are exhibited at London Bluff, nine miles below Shell Bluff, and a horizontal bed of the large oysters is exposed in a cliff two miles farther down the river. At Stony Bluff, on the borders of Scriven county, the calcareous deposit is no longer visible, the cliff being composed of silicious beds of the burr-stone and mill-stone series, resting upon brick-red and vermilion-colored loam. This section, Mr. Lyell states, is of great importance, as it concurs in proving that the mill-stone of this region, with its eocene fossils, is an integral part of the great red loam and sand formation usually devoid of organic remains. The burr-rock of Stony Bluff abounds with cavities and geodes partially filled with crystals of quartz and agates. In the fragments scattered over the adjacent fields, Mr. Lyell observed casts of univalves. At Millhaven, eight miles from Stony Bluff and five from the Savannah river, these silicious beds again crop out and afford casts of the genera Pecten, Eulima or Bonellia, and a Cidaris. It had been pierced through to the depth of twenty-six feet, and was associated with red loam, white sand and kaolin, affording further evidence of these deposits belonging to one formation.

One mile west of Jacksonborough, in the ford of Briar and Beaver Dam Creeks, is a limestone passing upwards into white marl which appears to have been deeply denudated, and is overlaid by sand that belongs to a formation of sand, loam, and ferruginous sand-rock, referred by Mr. Lyell to the red loam and burr-stone series. The limestone and marl, although rarely exposed in sections, are considered to constitute very generally the fundamental strata of the region on account of the not unfrequent occurrence of lime-sinks or circular depressions, formed in the beds of loam and sand by subterranean drainage. The fossils procured from the limestone of Jacksonborough by Mr. Lyell, as well as those presented to him by Col. Jones, of Millhaven, were for the greater part well-defined casts, and were specifically new to American palæontologists; nevertheless he has no hesitation, from their general aspect, to regard them as belonging to the eocene period. The genera enumerated in the paper are, Conus, Oliva, Bulla, Voluta, Buccinum, Fusus, Cerithium, Trochus, Calyptræa, Dentalium, Crassatella, Chama, Cardium, Cytherea, Lithodomus, Lucina, Pecten, and Ostrea. The Trochus is considered identical with the *T. aglutinans* which occurs in the Paris basin; and the Lithodomus to be undistinguishable from the *L. dactylus* of the West Indies, one of the few eocene Parisian fossils identified by Deshayes.

All the Bluffs examined by Mr. Lyell on the Savannah river below Briar Creek belong to the beds above the limestone, and are referable chiefly, if not entirely, to the burr-stone formation. In white clays exposed a few hundred yards below Tiger Leap in Hudson's Reach, the author found impressions of Mactra, Pecten and Cardita, also fragments of fishes' teeth, particularly of the genus Myliobates, likewise several teeth of the genus Lamna, and one belonging to a Notidamus or a nearly allied genus. At Sister's Ferry he observed not only the brick-red loam, with the red and gray clay and sand, but

* See pl. 10 of Morton's Synopsis.

a highly silicious clay, which though soft when moist, exhibits a conchoidal fracture when dry, and resembles flint; in some spots the clay also passes into a kind of menlite.

In conclusion, Mr. Lyell offers the following general observations: The part of South Carolina and Georgia which lies between the mountains and the Atlantic, and of which he examined a portion near the Santee and Savannah rivers, has a foundation of cretaceous rocks containing Belemnites, Exogyræ, &c., overlaid first by the eocene limestone and marls, and secondly by the burr-stone formation with the associated red loam, mottled clay, and yellow sand. According to Mr. Vanuxem's observations, a tertiary lignite deposit sometimes intervenes between the cretaceous and eocene series. The remarkable difference in the fossils of the eocene strata at different points, as the Grove on Cooper river, the Santee canal, Vance's Ferry, Shell Bluff, Jacksonborough, and Wilmington, might lead, Mr. Lyell states, to the suspicion of a considerable succession of minor divisions of the eocene period. That the whole are not precisely of the same age he is willing to believe, but he is inclined to ascribe the difference principally to two causes: 1st, that the number procured at each place is small and therefore represents only a fractional portion of the entire fauna of the period, so that variations in each locality may have arisen from original geographical circumstances; and 2ndly, no great eocene collection has been made from any part of the United States.

Some of the burr-stone fossils occur in the limestone, and Mr. Lyell thinks the former may bear to the latter a relation analogous to that which the upper marine sands of the Paris basin bear to the calcaire grosser.

With respect to the conclusion stated in the beginning of the paper, that he had been unable to find any beds containing an intermixture of cretaceous and tertiary fossils, Mr. Lyell says, it would require far more extended investigations to enable a geologist to declare whether there exist in the Southern States any beds of passage, but he affirms that the facts at present ascertained will not bear out such a conclusion.

The generic affinity of the cretaceous fossils of the United States to those of Europe, is stated to be most striking, and Mr. Lyell observed in Mr. Conrad's collection from Alabama a large Hippurite, a point of analogy not previously recorded.

The proportion of recent shells in the eocene strata of the United States appears to be as minute as in Europe, and the distinctness of the eocene and miocene testacea hitherto observed to be as great. Mr. Lyell says, it is also worthy of remark, that the recent shells found in the American miocene beds are not only in the same proportion to the extinct as those of the Suffolk crag, or the Faluns of Touraine, but that they also agree specifically in most cases with molusca inhabiting the neighboring sea; in the same manner as the recent miocene species of Touraine agree for the greater part with species now living on the Western coast of France or in the Mediterranean, and as the recent testacea of the crag are identifiable with species belonging to the British seas. This result appears to Mr. Lyell to confirm the accuracy of conchological determinations; for if, on the contrary, it should be maintained, that the number of recent species is so enormous, and different species resemble each other so closely as to have produced identifications from the mere difficulty of effecting discriminations, he would suggest that in that case, according to a fair calculation of chances, nine-tenths of the American miocene species hitherto identified ought to have been assimilated to exotic shells, instead of having been found to agree with some portions of the limited fauna at present known on the American shores. The same argument, he adds, is clearly applicable to the identifications which have been made of fossil and recent shells in the European tertiary formations.—*Philadelphia Magazine.*

The great step to greatness is to be honest.

KEEPING CATTLE WARM.

If we look abroad at the habits or necessities of people, we find that as we advance from south to north, the consumption of animal food increases. In hot climates, under the tropics for instance, the diet is almost exclusively a vegetable one. Under a latitude of forty or fifty degrees, we require considerable animal food—if we advance to the frozen regions of the north, whale oil and bears' fat, are found among the luxuries of the board. These gross materials, almost to the exclusion of vegetables, are there found indispensable to keep up the necessary supply of nutrition and warmth. It has been long known both to chemists and observing men, that a cold atmosphere requires an extra quantity of food to sustain life and health; and this observation is just as applicable to the cattle and horses whose home is at our barns, as it is to our own species. If they are kept warm—housed from the storm, and shielded from unnecessary exposure, they will need less food than if left unprotected through the winter in the open yard. In point of economy, then, as well as from kindliness of feeling, it is our interest to look to the comfort of our stock. The winter profit to be realized from milch cows, is unquestionably much affected by their treatment in this respect, and every one who would make the most of his cattle in this latitude, must carefully attend to their comfort. I copy the following remarks from the fourth part of Johnston's Agricultural lectures, as particularly in point. There is much practical matter in them, that may be made available by every intelligent farmer. The extracts now forwarded for the Cabinet, will, I think, confirm this assertion.—*Far. Cab.* N. S.

"The degree of warmth in which the animal is kept, or the temperature of the atmosphere in which it lives, affects the quantity of food which the animal requires to eat. The heat of the animal is inseparably connected with its respiration. The more frequently it breathes, the warmer it becomes, and the more carbon it throws off from its lungs. It is believed, indeed, by many, that the main purpose of respiration is to keep up the heat of the body, and that this heat is produced very much in the same way as in a common fire, by a slow combustion of that carbon which escapes in the shape of carbonic acid from the lungs. Place a man in a cold situation, and he will either starve or he will find some means of warming himself. He will probably take exercise, and by this means cause himself to breathe quicker. But to do this for a length of time, he must be supplied with more food. For not only does he give off more carbon from his lungs, but the exercise he takes causes a greater natural waste also of the substance of his body.

"So it is with all animals. The greater the difference between the temperature of the body and that of the atmosphere in which they live, the more food they require to 'feed the lamp of life,'—to keep them warm, that is, and to supply the natural waste. Hence the importance of plantations as a shelter from cold winds, to grazing stock—of open sheds, to protect fattening stock from the nightly dews and colds—and even of closer covering to quiet and gentle breeds of cattle or sheep, which feed without restlessness, and quickly fatten.

"A proper attention to the warmth of his cattle or sheep, therefore, is of great practical consequence to the feeder of stock. By keeping them warm, he diminishes the quantity of food which is necessary to sustain them, and leaves a larger portion for production of beef or mutton.

"Various experiments have been lately published which confirm the opinions above deduced from theoretical considerations. Of these I shall only mention one by Mr. Childers, in which twenty sheep were folded in the open field, and twenty of nearly equal weight, were placed under a shed in a yard. Both lots were fed for three months—January, February, and March—upon turnips, as many as they chose to eat, half a pound of linseed cake, and half a pint of barley each sheep, per day, with a little hay and salt. The sheep in the field consumed the same quantity of food, all the barley and oil cake, and about 19 lbs. of turnips per day, from the first to last, and increased on the whole 36 stone 8 lbs. Those under the shed consumed at first as much food as the others, but after the third week they eat 2 lbs. of turnips each less in the day, and in the ninth week, again 2 lbs. less, or only 15 lbs. a day. Of the linseed cake, they also eat about one-third less than the other lot, and yet they increased in weight 56 stone 6 lbs., or 20 stone more than the others.

"Thus the cold and exercise in the field caused the one lot to convert more of their food into dung, and the other more of it into mutton.

"The absence of light has also a material influence upon the effects of food increasing the size of animals. Whatever excites attention in an animal, awakens, disturbs, or makes it restless, appears to increase the natural waste, and to diminish the effect of food in rapidly enlarging the body. The rapidity with which fowls are fattened in the dark, is well known to rearers of poultry. In India, the habit prevails of sewing up the eyelids of the wild hog-deer, the spotted deer, and other wild animals, when netted in the jungles, with the view of taming and speedily fattening them. The absence of light indeed, however produced, seems to soothe and quiet all animals, to dispose them to rest, to make less food necessary, and to induce them to store up more of what they eat, in the form of fat and muscle.

"An experiment made by Mr. Morton, on the feeding of sheep shows the effect at once of shelter, of quiet, and of the absence of light upon the quantity of food eaten, and of mutton produced from it.

"Five sheep of nearly equal weights, were fed each with a pound of oats a day, and as much turnips as they chose to eat. One was fed in the open air, two in an open shed—one of them being confined in a crib—two more were fed in a close shed in the dark, and one of these also was confined in a crib, so as to lessen as much as possible the quantity of exercise it should take. The increase of live weight in each of the five, and the quantity of turnips they respectively consumed, appear in the following table:

	Live Weight. Nov. 18	Live Weight. Mar 9	Increase.	Turneps eaten.	Incr. for each 100 lbs.
	lbs.	lbs.	lbs.	lbs.	lbs.
Unsheltered	108	131 7	23.7	1912	1.2
In open sheds	102	129.8	27.8	1394	2.0
do. but confined in cribs	108	130.2	22.2	1238	1 8
In close shed in the dark	104	132.4	28.4	886	3.1
do. but confined in cribs	111	131.3	20 3	886	2.4

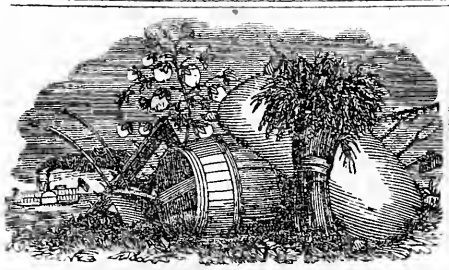
"From this table it appears, as we should have expected—

"That much less—one-third less—turnips were eaten by the animal which was sheltered by the open shed, than by that which was without shelter, while in live weight it gained four pounds more.

"That in the dark the quantity of turneps eaten was one half less, and the increase of weight a little greater still. But that when confined in cribs—though the food eaten might be a little less—the increase in weight was not so great. The animal, in fact, was fretful, and restless in confinement, and whatever produces this effect upon an animal, prevents or retards its fattening.

"That the most profitable return of mutton from the food consumed, is when the animal is kept under shelter and in the dark.

"Such a mode of keeping animals, however, must not be entered upon hastily, or without due consideration. The habits of the breed must be taken into account; the effect of confinement upon their health must be frequently attended to, and above all the ready admission of fresh air and a good ventilation must not be forgotten. By a neglect of the proper precautions, unfortunate results have frequently been obtained, and a sound practice brought into disrepute."



The Southern Cultivator.

AUGUSTA, GA.

SATURDAY, FEBRUARY 1, 1845.

To our Exchanges.—Those Agricultural Journals with which we exchange will confer a favor by addressing to us at Athens in future.

FRIENDS AND PATRONS!

The publishers beg leave to say a word to you, to induce you to make an effort to increase the circulation of the "Southern Cultivator." The work is devoted to the interests of the planter, and looks alone to them for support. What shall we, what can we say, to induce you to make an exertion in its behalf? Shall we tell you, that notwithstanding we have incurred the expense of engaging the services of one of the ablest agricultural writers in the South as its editor, and that although one month of the year has expired, we have not as yet received a sufficient amount from subscriptions to cover *one-half the expense of setting the type?* We might tell you this, and tell you the truth! Are you willing, Planters of the South, that our efforts in your behalf shall be thus rewarded? If you are not, it is time that you bestir yourselves; for we assure you the work cannot be sustained, without an immense sacrifice on our part, unless you exert yourselves to extend its circulation. We will not now say more—we could not in justice to you or ourselves have said less. The Publishers.

Acknowledgements.—We are indebted to the editor of the Albany Cultivator for a copy of his Agricultural Almanac, for 1845; to R. Peters, jr., Esq., of Augusta, for the 1st No. of Colman's European Agriculture; to Judge Hillyer, for a copy of the letter of Richard Rush, Secretary of the Treasury of the United States, on the growth and manufacture of Silk; and to the Hon. A. H. Stephens, for a specimen No. of the Ohio Cultivator.

We are under particular obligations to those editors of the political press in the South, who have published our prospectus, and commended our enterprise to the public, in their editorial columns.

Hemp.—Those who think of trying to raise hemp, are referred to the article on another page, by Mr. Clay. It contains everything necessary to a full understanding of the whole process: indeed, it is a complete treatise in itself, strongly marked by the true characteristics of genius—clearness and simplicity. It is, alone, worth ten whole years' subscription to the Cultivator.

In our next number, we intend to republish the treatise on the culture and water-rotting of hemp, by *David Myerle*, addressed to the farmers of Missouri, the great hemp region of the west.

With these sources of information, and their rich lands, if our friends in northwestern Georgia, don't succeed in making money by hemp, they ought to be condemned never again to know what the jingle of silver is.

Keeping Cattle Warm.—This number of the Cultivator contains an article on keeping cattle warm, to which the reader's attention is especially directed With southern planters, neglect in this matter is by far too prevalent. Even in our mild climate it is idle waste of time and money to attempt any effectual improvement in our stock, until our negligent habits in this respect shall have been corrected; and surely they will be corrected as soon as it is understood how much our interest suffers from indulgence in them. If proof is wanted how deeply the planter's stock of winter provender is affected by every cold rain during winter and spring, for the want of close, warm houses for his stock of every description, he has only to turn to the statements in the article referred to: and if he would understand fully the philosophy of the whole matter, he has only to attend carefully to what Liebig says on the general subject of animal heat. It is, by the way, one of the most beautiful philosophical disquisitions in the whole of his Organic Chemistry. And though the reasoning employed has reference, chiefly, to the human body, yet, the whole animal creation obeying very nearly the same general laws, as regards nutrition and the sustenance of life, it may be regarded as true in reference to the cattle-yard as well as to the parlor.

"In different climates," says Liebig, "the quantity of oxygen introduced into the system of respiration, as has been already shown, varies according to the temperature of the external air; the quantity of inspired oxygen increases with the loss of heat by external cooling, and the quantity of carbon or hydrogen necessary to combine with this oxygen must be increased in the same ratio.

"It is evident that the supply of the heat lost by cooling is effected by the mutual action of the elements of the food and the inspired oxygen, which combine together. To make use of a familiar, but not on that account a less just illustration, the animal body acts, in this respect, as a furnace, which we supply with fuel. It signifies nothing what intermediate forms food may assume, what changes it may undergo in the body, the last change is uniformly the conversion of its carbon into carbonic acid, and of its hydrogen into water; the unassimilated nitrogen of the food, along with the unburned or unoxidised carbon, is expelled in the urine or in the solid excrements. In order to keep up in the furnace a constant temperature, we must vary the supply of fuel according to the external temperature, that is, according to the supply of oxygen.

"In the animal body the food is the fuel; with a proper supply of oxygen we obtain the heat given out during its oxidation or combustion. In winter, when we take exercise in a cold atmosphere, and when consequently the amount of inspired oxygen increases, the necessity for food containing carbon and hydrogen increases in the same ratio; and by gratifying the appetite thus excited, we obtain the most efficient protection against the most piercing cold. A starving man is soon frozen to death; and every one knows that the animals of prey in the arctic regions far exceed in voracity those of the torrid zone. * * * * *

"Our clothing is merely an equivalent for a certain amount of food. The more warmly we are clothed, the less urgent becomes the appetite for food; because the loss of heat by cooling, and consequently the amount of heat to be supplied by the food, is diminished.

"If we were to go naked like certain savage tribes, or if, in hunting or fishing, we were exposed to the same degree of cold as the Samoyedes, we should be able, with ease, to consume ten pounds of flesh, and perhaps a dozen tallow candles into the bargain, daily, as warmly clad travellers have related with astonishment of these people. We should then also be able to take the same quantity of brandy or train oil without bad effects, because the carbon and hydrogen of these substances would only suffice to keep up the equilibrium between the external temperature and that of our bodies.

"According to the preceding expositions, the quantity of food is regulated by the number of respirations, by the temperature of the air, and by the amount of heat given off to the surrounding medium. * * * *

"The cooling of the body, by whatever cause it may be produced, increases the amount of food necessary. The mere exposure to the open air, in a carriage or on the deck of a ship, by increasing radiation and vaporation, increases the loss of heat, and compels us to eat more than usual." * * * *

Lindley's Outline.—We have commenced in this number the publication of a very important work, viz: Prof. Lindley's Outline of the First Principles of Horticulture. Though, from its title, it would at first appear to be not very intimately connected with the scope and design of this work, yet, when it is remembered that the term Horticulture properly means that branch of knowledge which relates to the cultivation, multiplication and amelioration of the Vegetable Kingdom, its intimate connection with the business of the planter is at once manifest.

The character of Prof. Lindley is a sufficient guarantee of the accuracy of anything laid down by him as a first principle. We can, therefore, confidently recommend to our readers, not merely an attentive perusal, but a careful study of his Outline, as it shall appear in the successive numbers of the Cultivator. "It is, at once, remarkably simple, and highly philosophical; free from superfluous technicalities, and, at the same time, truly scientific. Without entering into tedious subordinate details, it offers a lucid explanation of the general nature of vegetable actions, and of the important principles which lie at the foundation of all the operations of Horticulture."

"A knowledge of these leading principles at once invests with new and peculiar interest even the most mechanical, and apparently unmeaning and irksome details of art. With what increased satisfaction are the common processes of manuring or transplanting carried on, to say

nothing of the more delicate operations of budding, grafting, propagating by layers, &c., when we are acquainted with the structure of the plants we are endeavoring to control, and comprehend the why and the wherefore of every step we pursue. With this knowledge of vital actions, new modes of culture, and various improvements in the operations of the art, are continually suggested to the reflective mind; which derives additional pleasure from the prosecution of scientific experiments, of which the ignorant laborer, who turns over the soil and sows his seeds in precisely the same manner under all circumstances, never dreams."—*A. J. Downing's Preface.*

European Farming.—To those who are acquainted only with the system of culture pursued in the southern States, the enormous rents paid for land in Europe, and the prodigious amounts of produce obtained from it, must appear altogether incredible. Yet, even at the risk of being charged with exaggeration, we have thrown together a few statements, gathered from our exchange papers, on this subject, for the purpose of showing what thorough cultivation of the soil will accomplish.

In Great Britain and Ireland nearly all the lands that are cultivated, are let to tenants. These tenants pay an annual rent of from four to five pounds sterling: equal to twenty or twenty-five dollars per acre. Paying rent at these rates, they have to pay, besides, enormous taxes to both church and state, and find all the means, such as labor, manure, implements, &c., that are necessary to carry on the business of the farm profitably.

In the year 1811, a certain farm in England of 890 acres, was estimated to produce $38,000. The manure that was applied that year was 13,746 one-horse cart loads. The rent was $12 per acre; the manure cost $12 per acre; and interest, taxes, expenses of cultivation, &c., amounted to $12 more per acre. And yet after all these disbursements, there was a nett profit of between 6 and 7 dollars per acre to the tenant.

We notice this farther statement, that near London, a hay farm of 160 acres, was rented at $12 per acre. A very heavy expenditure was incurred for manure; yet the tenant, even under these circumstances, has become wealthy.

In Ireland, a poor man rented a single acre of ground; built his cottage, and bought his tools and manure, at high rates. He bought his seed, paid a church tax, supported a family of four persons besides himself and his wife, and the first year cleared all expenses and had £8, or near forty dollars left.

These statements, to those acquainted only with southern cultivation, as we have said, appear utterly incredible. Yet they come to us in such a way as to command our belief. And these wonderful results are accounted for, by those who relate them, on a single principle, viz: *thorough cultivation.* In this, they say, consists the whole mystery.

The people of the United States are beginning to understand these things. We remember seeing, some years ago, a statement that 212 bushels of corn had been gathered from an acre in the State of New York. And we have now before us the Report of the Middlesex County Agricultural Society's Committee on Field Crops, in which it is stated that even in Connecticut *one hundred and fifty one bushels and eighteen quarts* of corn to the acre have been produced on the farm of Mr. Wadsworth. Who, knowing these results, and having the spirit and energy of a man, would continue the system of *skinning* ten acres to get what ought to be produced by one?

Pictures.—We are fully aware of the additional interest thrown around an agricultural paper, by introducing into it representations of fine stock: and we are resolved that, if possible, the Cultivator shall not be wanting in this attractive feature. But we must first be assured of the means of making such expensive additions to it. The whole enterprise is in the hands of southern planters. They can make or mar it.

The extensive circulation of the Albany Cultivator, we have no doubt has been obtained, in part, by its beautiful pictures of beautiful stock. And with this circulation its influence has gone on increasing. Its January number contains a most exquisite engraving of a cow, which cost —not the cow—but the picture of the cow cost over *two hundred dollars.* Well, with its *twenty-five thousand* subscribers, all, without a single exception, paying their subscriptions in advance promptly and punctually, it can well afford to pay for such pictures.

When southern planters display the like spirit with northern farmers in supporting a publication devoted to the promotion of their best interests, they will have a paper that will contain everything they can possibly desire, either as to reading matter or illustrations.

The Agricultural Press.—Nearly all our exchange papers, for the month of January, have come to hand greatly improved, in almost every respect, from what they were last year; and what is better, their editors, in most instances, speak exultingly of the encouragement they have received, and of their prospects for the future. This is all just as it should be, and goes to show that the great mass of the people who are engaged in tilling the ground, are rapidly conquering their prejudices against book farming, and are beginning to place the proper estimate on the labors of those who are engaged in furnishing them with correct information on the subject of their everyday business. An editor, lately of the interior of New York, now of Ohio, was a welcome inmate in every farm house where he was known—had free passage in every stage in the State, and free quarters in all the village hotels: and all this in addition to an extensive subscription list, promptly paid in advance. That was doing the thing cleverly; and appearances now are that since his removal to Ohio, the people of that State are not going to be outdone in this sort of substantial courtesy by their neighbors, the people of New York. Hence it is, that men having the capacity to serve the people, are willing to engage in their service, and when so engaged, and thus treated, cheerfully devote their whole energies to that service.

How very different the state of things in this respect, now, and twenty-five years ago, when Mr. Skinner, the father of the Agricultural press in the United States, commenced the American Farmer, without a single subscriber! His first number extended to only five hundred copies; and though it was first arranged to be dated on the *first of April*, yet it was altered to a different date, to avoid the ridicule of the possible failure of a *fool's project*, commenced on *all fool's day.*

Cotton.—Those planters who are thinking about increasing their crops, so as to make up for the reduction in price, would do well to consider carefully what they are going to do. Let them look at the facts disclosed by Prof. McCay's statement, hereunto annexed, before they determine on a course so suicidal.

We must remark, however, that over-production is, by no means, the only cause; and that it is very far indeed from being the most efficient cause of the present ruinously low price of our great staple. Outrageously unjust, unequal and oppressive national legislation—such as no free people, having the means of resistance, ought to submit to for a single day, is at the bottom of most of the disasters the South is now suffering. The *effect* is the same; and if those who, with their feet on our necks, and their hands in our pockets, are fleecing us on all sides, can persuade us that the *cause* of our ruin lies, not with them, but with ourselves, their great end is answered. They are enriched—we are humbugged, plundered and ruined.

THE COTTON TRADE.

Professor McCay, of the University of Georgia, in a well considered article in the Merchant's Magazine, thus sums up the probable production of Cotton for the past year, and its probable consumption for the year to come.

	Bales.
United States Crop	2,460,000
English Import from India	159,000
English Import from other places	140,000
Total supply	2,750,000

	Bales.
Wants of the United States	370,000
" France from the U. States	420,000
" the Continent from "	180,000
" England	1,480,000
	2,450,000
Excess of supply	300,000

Mr. McCay anticipates that this additional burthen will be felt very severely. We must confess that we think so too. Since he wrote his article, cotton has fallen considerably, and is at this moment according to quality, from ⅛ to ¾d. per pound lower than ever before known in England, and full ¼ to ⅜ of a cent in our own country.

If our planters go on increasing their production, cotton will soon not be worth over 2 to 5 cents per lb., according to quality, on the plantation. At this price no man can live by it. What is the remedy? Simply, raise less of this and more of other products. Here is one thing for example. We believe that a pound of fine Merino wool may be raised in that part of the south suitable for keeping sheep, as cheaply as three pounds of cotton can be grown. The former would be worth 40 cents on the plantation at the lowest, the latter not to exceed 12 cents, which makes a difference in favor of wool-growing of more than 300 per ct.

But we hear the planters say, well, when we get to raising wool, the price of that must fall too. Suppose it does? It will still be a profitable business even at 20 cents per pound; for sheep will enrich your lands and fit them for other good crops, while cotton impoverishes them. Yet so long as we import wool, (which we still continue to do,) there is little prospect of its becoming lower; and when we have supplied ourselves, we can then look abroad for a market. Great Britain alone imports nearly, if not quite, 50,000,000 lbs. annually, and France a considerable quantity. Here, then, is a chance of a market for a long time; for we only raise now about three-fifths of what Great Britain alone imports, and it would be years before we could reach the production of 50,000,000. In the meanwhile it must be recollected that our own consumption will be rapidly on the increase. Space forbids our pursuing this subject any further in this No., but we intend to revert to the general subject of growing wool in our next.—*American Agriculturist.*

For the Southern Cultivator.

INDIGO.

Mr. Editor:—As I am anxious to see a portion of the labor at the South diverted from the culture of cotton, and know no better way of doing it than by commencing it myself, I would be glad if you would furnish me with some account of the culture and manufacture of Indigo—the probable quantity raised to the acre, and what soil is best adapted to it. Any information on this subject would be interesting, and at the same time obliging to Yours, &c.

Waynesboro', Dec. 21, 1844.

Remarks.—We are glad to find that men's minds are beginning to be turned to other agricultural products besides cotton. The condition of things in the cotton-growing States imperiously demands it. Those who, like our correspondent, are thinking of Indigo, will, on referring to the many sources of information that are extant on the subject, find its culture a very simple business indeed. The profit is another matter, which has to be tried yet.

We design hereafter giving in the Cultivator the information sought for. For the present, we can only refer inquirers to the following, viz:—

For the Southern Cultivator.

FINE STOCK HOGS.

Mr. Editor:—I am quite a small farmer, though I generally raise my own pork and corn. Last September, I was in company with several gentlemen, who were conversing on the subject of hogs. I observed that I would give a pig six months old, to any gentleman that would beat me in weight, on from twenty to thirty hogs, not to exceed two years old, raised on his own farm. Capt. Wm. G. Smith, of Jasper County, (though not present,) sent me word he would take the banter on twenty-five. His twenty-five weighed 7238 pounds, average 289½. My twenty-five weighed 7332 pounds, average 293¼. Mine were the common stock, land pikes, if you please. Should there be any persons that are raising the same breeds, that have taken no more pains with them than farmers ordinarily do with their stock of hogs, I should like to hear from them.

Respectfully, John Webb.

P. S. I have a fine Berkshire Boar, of Col. John Bonner's stock, two years old 25th April next, for sale; Price, $20.

Webbs, Ga., Jan. 10, 1845.

Hauling it back.—We are informed, says the Columbus (Ga.) Enquirer of 22d inst., that James Dowdell, Esq., of Harris County, who has for some time past had his Cotton in the Warehouse of this city, during the past week sent his teams down and had it hauled home, preferring to hold it over, rather than sell it at the present beggarly prices. Although he *may* not *make* anything by the operation, he is pretty certain not to *lose*.

For the Southern Cultivator.

OVERSEERS.

Mr. Editor:—Much has been said recently in the columns of the Carolinian, in regard to the improvement and duty of overseers; but it seems to me some exciting cause must first exist before men can be roused to great energetic action, leading to a permanent improvement in anything. Let us examine and see if any of these causes now exist on the part of overseer or employer. At the present time the country is filled with men looking for business as overseers. Many have left their employers (not turned off) because they will not and cannot give the same wages in 1845 as they did the last year. Others have left their homes, where they have only been able to make a scanty support, if that, to seek an overseer's birth. Many, may I not say one-half, of this number, will not be able to find business: and the reason why, must be obvious to every green seed cotton planter at least. I venture nothing in saying that we have men enough, of good character too, who have for many years employed overseers, but would now most willingly themselves become one, provided such a price could be obtained for their services as has been common among farmers and overseers for years past. But who among the green seed planters are able to give high wages to even men of character? Many who have employed overseers for years past, will not do so in 1845, because the price asked forbids at once the farmer to give it. Where then will be found these necessary exciting causes on the part of overseer or employer to prompt them to improvement? Surely not the high price the one will be able to obtain for his services, or the other able to give. The fact is, the overseer's business is retrograding daily; and that large retrenchments, as regards numbers and wages, will be made among this class of men in 1845, I believe no one will undertake to deny.

Now the question is, how are we to cure these evils so justly complained of? It would be vain to suppose for a moment that individual action alone could remove them; while a united action on the part of farmers will fully accomplish the object aimed at. And, for this purpose, I now call upon one and all of my brother farmers throughout the cotton growing States to join me in a remedy, to cure the evils spoken of, as practicable as it is sure in the end; and one which is ready at hand and fully alike in the power of all to participate. "A long pull, a strong pull, and a pull altogether," will consummate this great work of reform as sure as there is day and night.

And first, I propose we plant, in 1845, only one-half the number of acres in cotton that we did in 1844: from which, by a more careful tillage and concentrated manure, (best in hills,) we can make at least two-thirds as much as we have made this year; reducing the present overproduction down to one million, three hundred and fifty thousand bales; for which we shall be able to obtain at least from 9 to 10 cents per lb.: netting the farmer over one-fourth more money than the whole of his present crop, supposing it to average him 5½ cents. This plan adopted, we shall be able to withdraw from our cotton field—not one-half of our hands, because our cotton, corn, and everything else, is to be cultivated in a much better style than heretofore—but *one-third*, to be busily employed the whole year in clearing out old filled-up ditches; repairing, in fact making new, fences, for the first time, perhaps, in ten years, out of new rails; dispensing with the present plan of grape vine and rotten pole fences. And, in the mean time, never to lose sight, for a moment, of our compost heaps, to which we can add daily with our withdrawn hands; reducing, at the same time, our stock of horses and mules *one-third, if no more*, and, consequently, lessening our expenses in the implements of husbandry, and increasing the number of our hogs, with the food these horses and mules would otherwise eat, for the use of our negroes.

This done, in 1845, I farther propose to every cotton planter in the United States, that we plant in 1846, the other half of our cotton field, (not more,) which remained fallow in 1845; from which we shall, with great ease, be able (from our augmented compost heaps, made with these withdrawn hands, concentrated in hills upon this rested land, with garden-like tillage) to produce, at least a full three-fourth crop; say something over one and an half million bales, which will readily sell (as the Liverpool warehouses and all others now packed to bursting point with our over stock of cotton at 4 and 5 cents, will be emptied of their burthen) at from 10½ to 12 cents: netting the farmer something more than 50 per cent over his full crop of 1844. Surely I may venture to say, by this time we shall be in somewhat a better humor and shall be able, and I doubt not will feel more disposed, to hire and give our overseers such wages as will rouse them to at least a generous emulation in the arts of husbandry, during this period of two years at least, and I should say for ever afterwards.

Let every farmer raise his own hogs, horses, mules, sheep, stock of every kind, and withal make his own negro cloth at home; and all who live south of 34 degrees make their own sugar; not forgetting to bind ourselves to use for the packing of our cotton our own domestic cotton bagging and rope. A patronage of this kind will at once enable the manufacturers of these articles to put them at the lowest possible price.

And how shall we begin this work? Permit me, with all due deference, to suggest the plan of State Conventions, and then a General Convention of the cotton growing States, to meet at some central point, to adopt such measures as will carry this work into effect; or, I will unite in any other plan that may be suggested, which will lead to success. I ask again, will the present oppressed cotton planters unite with me to consummate this grand work of reform? If so, the work will be done, and much more accomplished than has been conceived in the foregoing plan. But if you refuse me your friendly aid in this work, permit me, gentlemen, to lay before you the price of our cotton crop in the fall of 1845 and spring of 1846, if a full average one should be made the next year. Here it is under the different classifications:—Inferior, 2 to 2¼; middling fair, 2½ to 3; fully fair, 3½ to 3¾; *choice*, 4 to 4½, of which *class* there will be but little. The writer of this will be ready at any moment to pledge himself to reduce his cotton field of 520 acres, planted this year, to 250 the next, provided like pledges are made on the part of every cotton planter in the United States. But should there be a failure of this united pledge on their part, then he promises on his part still to be faithful, and not forsake his oppressed and suffering brethren of the plow, but shall feel compelled to aid and assist them with all his might in reducing the price of cotton in the fall of 1845 and spring of 1846 to the prices herein set forth, by planting his usual number of 520 acres in cotton, if no more.

And it may not be improper or irrelevant to state that he has now ready for use upwards of 800 yards of negro cloth spun and wove from the wool of his own sheep, and will add that from 1827 to 1826 he made his own sugar—a simple and easy process—and intends, if life last, to do so in future. Has raised his own horses, even more than were necessary for plantation use, for the last sixteen years; also, an ample supply of hogs for both white and black, and manufactured, in part, his own negro shoes.

I have much more to say upon this important subject, so flattering to the pride of my ambition, which will be done in due time in a subsequent communication. In the mean time, I can but hope the attention of the cotton planter will be turned and fixed upon this grand scheme of reform, and his best and most serious thoughts bestowed leading direct to its final consummation. Agricola.

A western editor, noticing a new mode of fattening hogs, says he has tried it *himself*, and finds it unexceptionable.

For the Southern Cultivator.

PLANTERS' CLUB OF HANCOCK.

REPORTS READ BEFORE THE CLUB.

REPORT of the Tillage and Product of one Acre of Land in Corn, by RICHARD S. HARDWICK, in 1844.

The acre selected was worn out red land, having a little more silex than is usual for red land in this county. It would not have produced more than four bushels per acre without manure, with good culture and good season. The *Bommer manure* was used for the experiment; and although it was a failure, and but few would like to make a report, I am induced to do so, first, because it is my duty as a member of your Club; and secondly, because there is as much, or more, to be learned from failures, as from successful experiments, by the thinking class of farmers. At any rate, it points out the rock on which the experimenters split, and enables others to direct their experimental bark around it.

The manure was oak leaves and pine straw, hauled from the woods, and weeds cut from the corners of the fence and branch sides, and put up the last of September, 1843, on the Bommer method, and remained in the kilns till March, 1844. There were 70 ox-cart loads used. The method of applying will presently be given. The first operation on the land, was about the first of February, with a colter plow, deep and close. The land was, however, rather dry for the work to be done as effectually as it should have been. About the middle of March, the land was put in prime condition by a good rain. The manure (70 loads) was then spread, such portion as seemed to be necessary, reserving enough for future application and in a different way, hereafter described, and plowed in with a turning plow, furrow followed by a colter in the bottom. This done, the land was laid off in rows, at the distance of 7 feet, which furrows were re-opened with a double turner, in order to open them deep and well. In this furrow, a part of the manure was put, say filled half full; the rows were then bedded out complete. A furrow was then run on each side of the centre of this bed, at the distance of 12 inches from the centre, which placed the two rows two feet apart. A hand full of the remaining manure was then placed in those furrows at the distance of 24 inches, taking care, however, not to have the hills opposite, but by measurement to have the hills in the rows precisely half way between the hills in the other row, which made the hills present the diamond form. On this manure I put my corn, and covered it with a hoe. The planting was the 20th March.

The first operation was about the 20th April, by siding the corn with a colter, plowing out the wide rows with the scooter; for you will perceive from the method of planting that every other row was 5 feet wide—the other, or narrow rows, 2 feet wide. Corn flat wed and thinned to one stalk. About the middle of May, the wide rows were plowed with a turning plow, deep and well; and between the narrow rows, chopped with a hoe. Early in June, the wide rows were plowed very lightly with a sweeper; the narrow rows chopped, and flat hills put to the corn, which finished the cultivation. The season was good and the yield only 14 bushels. The land was measured by T. H. Audas, and the corn measured by G. W. Hardwick.

A very important question now arises, what was the cause of the failure? Is the Bommer manure worthless? Or is the defect in the method of planting or culture? I am of opinion, that the failure is chargeable to neither of those causes; and as the cause of failure is the most important part of my report, I must ask the indulgence of the Club in a few speculations on the cause of failure. It is well known to every practical farmer, that a piece of exhausted land, with any kind of manure, however good, and judiciously applied, cannot be made productive the first year of its application as well as it will after the manure and earth have become assimilated together; or, in other words, as when the earth has fully taken up the salts of the manure; therefore this may be set down as one of the causes of the failure.

This opinion is strengthened from the fact, that, the manure had not undergone decomposition enough to let out the salts for some time after its application. It was in what would be called the long state, but having a strong smell of ammonia, having been well saturated with the *lees*, which is well calculated to bring about decomposition, therefore it possessed all the elements of manure, but was not able to let them loose in time for the crop, the land of itself having but little of the elements necessary for the food of plants. The plot, of course, failed, before the necessary quantity or quality of the proper nutriment was afforded by the manure which had been applied. I am sustained in this opinion from this fact: in the summer of 1843, I made my first experiment in making the Bommer manure. In August of that year, when I sowed my turneps, I directed the manure spoken of to be applied to a part of my turnep land; it was hauled and thrown over in the corner of the fence in the long stage, about as that applied to my corn, but by the neglect of my overseer, was not applied. It remained there until spring In planting the turnep land in corn, and manuring in the hill with stable manure, I discovered my Bommer manure, hauled there the previous summer, in a fine decomposd state. I directed it to be applied in the hills, in the same quantity and manner that the stable manure was applied, and stakes drove down at the beginning and finishing row. I noticed those rows attentively through the crop season, and they perceptibly had the advantage of the rows on each side. Again, this acre of land was sown in wheat early in October, after having a slight sprinkling of manure from the cow-pen. The wheat now (6th December, 1844) is much larger (so much so that the difference is perceptible half a mile) than wheat sown the same day on land that produced me this year 40 bushels of corn per acre, with as much manure applied to it as was to the Bommer acre. These facts seem conclusive that my position is correct.

But another reason. It is a general opinion that fibrous rooted and slick leaved plants, are finer feeders than the tap or bulbous rooted with porous leaves; therefore the food that will have been used by the other plants, was rejected by the corn.

Again, the quantity of manure used in the long stage, as this was, I have no doubt was in the way of the young and tender roots, running out in search of food, as well as the scarcity or improper quality of food; for, on examination, when the corn was at maturity, I found that the roots had not run out into the rows, but were confined to the hill entirely. Now, if the body of the land had been rich, or in other words, had it abounded with the necessary food for the plant, they would have passed each other in the rows of five feet. There being no inducement, or rather nothing to draw them out, they had to content themselves in a small space and dwindle out a miserable existence in poverty and want.

But another reason, which has been given to me by a friend, whose good sense and opinions I have great confidence in, but differ from him, at least in part, of the view he takes.

He contends, in opposition to the opinion entertained by myself, that the salts of the manure are let loose, notwithstanding the manure was in the long stage and not sufficiently decomposed; that the manure being fully saturated with the *lees* which is the very essence of the manure, there being a natural affinity between that and the earth, that is, it was let out to the earth through the same pores that it was taken up, but the food was too strong for the plant in its infancy, therefore an unhealthy disposition was created, from which the plant never recovered.

In support of this opinion there is one fact worthy of notice, and it is, that the corn presented a yellow appearance from the time it came up until it began to tassel, when it improved in its color a little, but at no period did it present a healthy appearance. On one corner of this lot the land had been some little benefitted the year previous, by feeding some sows and pigs at that place. It was, however, but a very small place. At that place, the corn was never yellow; it presented a green healthy appearance through the whole season, and if the whole acre had done as well as that small spot, I should have made some 60 bushels, for on that corner I made pretty much all that I did make; therefore the difference to be settled between us, is, whether it was more from the want of food than from the strength or improper quality of it. His reasoning, however, is not without some weight; for the reason of the corn thriving well in the corner above referred to, may be, that it had other and more suitable food; therefore it rejected that which would have proved prejudicial to it, while the other having no other resource, was compelled to accept such as it could get.

I have now, gentlemen, given you my reasons at length for my failure, and if I was sure they were correct, it would very much relieve the mortification which I feel at a *book* farmer's making so signal a failure.

Sparta, Dec. 26, 1844. R. S. HARDWICK.

REPORT of the Tillage and Product of one Acre of Land in Corn, by BENJ. T. HARRIS, in 1844.

The land very much exhausted by continued cultivation for more than forty years. The soil chocolate. Previous crop, oats. Would consider two and a half barrels a good crop under the old system. Yield, 49 bushels and a ½ peck. Gathered and accurately measured on 28th August.

Preparation.—On 8th March, scootered the land deep and close, with a colter following in each furrow. On 21st March, spread 35 loads of lot manure, broadcast, and scootered again. On 22d, harrowed over the ground and laid off rows 4 feet 10 inches apart; strewed cotton seed (germ destroyed) in this furrow thickly, and listed on it with scooter plow, then dropped a handful of ordinary size 18 to 20 inches asunder in the planting furrow, and a small handful of leached ashes on each deposite of seed. Dropped the corn between those deposites, from 3 to 5 grains, and covered with a scooter plow. Middles plowed out with same plow, and cotton seed strewed in all the furrows except the last. Corn came up well. Some few hills destroyed by the bug.

Cultivation.—On 15th April harrowed it over with a fine-tooth harrowed, running 5 times in the row, the object of which, was to break the crust formed on the surface, which was so thick as to exclude the atmosphere. On 23d April ran the colter around the corn and plowed the middles with a scooter. On 24th, hoed and thinned to one stalk, where the stand was regular, and to two where it was irregular. On 10th May, run the sweep six times in the row. On 24th, sided with shovel plow, and run 4 turning plow furrows, finishing middles with shovel plow. June 5, laid the corn by, with sweepers. June 15, laid by with hoes, putting but little dirt to the corn. Remainder of ashes spread broadcast at the time of planting; quantity used, 3 cart loads, drawn by one yoke of oxen; the same quantity of cotton seed—making in all 41 loads of manure.

Recapitulation of Work.—Plowings, 2; sweepings, 2; harrowing, 1; hoeings, 2.

B. F. HARRIS.

REPORT of the Tillage and Product of one Acre of Land in Corn, by Mrs. MARTHA ANNE LEWIS, in 1844.

The soil is grey, post oak land, in a fine state of cultivation, having been kept as a barley lot, early corn, &c. Would have produced, with ordinary culture and good season, without manure, 5 or 6 barrels of corn per acre. Sixty-four loads of manure used; 10 of which was from the stable, 3 of cotton seed, and the balance from the hog pen, and applied as hereinafter stated. The land was broke with a scooter plow, from 15th to 20th January, 1844; then manured broadcast with the largest part of the manure, reserving enough for a subsequent ap-

plication. The manure thus spread was turned in with a turning plow about the middle of February. The 3 loads of cotton seed were spread and turned in, on 20th March, and re-turned on 22d with same plow; then laid off 4 feet 10 inches—furrows well opened, and planted 2 feet apart, 2 grains in a hill, a handful of manure put in the furrow on each side of the corn, and all covered by running a scooter furrow on each side, making a ridge over the corn. When the corn should have been coming up, the top of the ridge was scraped off with a board.

Culture.—The first operation was weeding with a hoe; then sided with a scooter plow, finishing the middles with a turning plow; then wed again; then plowed with a sweeper; then a flat hill on one side of each hill of corn, and in about two weeks thereafter the other side hilled in the same way, which completed the cultivation.

The dates of the several workings are not recollected; but it is proper to state that the various workings succeeded each other about two weeks. The season was good, and the product 96 bushels 1½ gallons of corn, and 1561 lbs. of fodder. The land and corn and fodder all accurately measured and weighed by competent disinterested persons.

MARTHA ANNE LEWIS.

Sparta, Dec. 26, 1844.

REPORT of the Tillage and Product of one Acre of Land in Corn, by THOMAS C. GRIMES, in 1844.

The land is a stiff red mulatto soil. I put on, broadcast, 400 bushels stable manure; then coltered each way; then opened a furrow, and in that drilled the corn, and put in, also, some cotton seed as manure. The field was laid off in this way, every 3½ feet, and so planted.

I plowed this corn three times. The first time I sided with a colter and swept out the middles. The second time I plowed it out with a turning plow; and the third time, swept it. I hoed it twice—once when small, and laid it by with the hoe. I thinned it out to about 18 inches in the drill. The season was favorable, except in July, when it suffered exceedingly from a drought, so much so, the stalks fired to the ears, about the time the grain was forming. The product from one acre, 64 bushels and 3 pecks.

THOMAS C. GRIMES.

Sparta, Dec. 26, 1844.

REPORT of the Tillage and Product of one Acre of Land in Wheat, by WILLIAM TERRELL, in 1844.

The land was plowed twice—well broken up and deep; after which there was applied to the surface from 20 to 25 bushels cotton seed, the vegetable principle having been destroyed in the seed by having lain in a heap till heated. After the cotton seed was applied broadcast, the wheat was sown and plowed in lightly, and the ground levelled by drawing over it a heavy brush, which left it smooth. There was sown on the acre one bushel of wheat called the Moore wheat, from Warren county, on the 5th October, 1843, and cut about the 12th May, 1844. Product 25 and ⅜ bushels. WM. TERRELL.

Sparta, Dec. 26, 1844.

REPORT of the Tillage and Product of one Acre of Land in Wheat, by E. M. PENDLETON, in 1844

About one-fourth of my land is a dark, rich, loamy soil, lying in a shallow bottom or valley, and the remainder grey and quite thin, skirting a gentle slope of rising ground. Had been in constant cultivation for many years, principally in corn. I sowed without any reference to premium, about the 10th October, 1843, after corn and peas had been gathered, and ground been turned over with an iron turning plow. Put about a bushel and a quarter of seed to the acre, of little white wheat, soaked in brine and sprinkled with lime. Plowed in with a scooter, harrowed and rolled, made water furrows in the bottom part, as it had been very wet even for corn. About the first of February, came to the conclusion to offer for a premium, and scattered some fifty or seventy-five bushels of cotton seed over it, which told well considering the lateness of the application.

Cradled early in June, and whipped out by hand, 19¼ bushels fine merchantable wheat. It was free from cockle, smut, and every other foreign body. The measure used was subsequently found to be a little too large.

The cost of cultivation, manure and gathering was about $12. The value of the wheat, straw and chaff, about $24—leaving $12 profit.

Sparta, Dec. 26, 1844. E. M. PENDLETON.

REPORT of the Culture and Product of one Acre of Land in Cotton, by RICHARD P. SASNETT, in 1844.

Soil gray or sandy, good clay foundation; would produce 800 lbs. cotton per acre, without manure, February 14th, had the land coltered, and water from ditch in horse lot sprinkled over part of it, say two-thirds; had no means of ascertaining the quantity. March 6, had it plowed deep with a scooter plow, following in the same furrow with a colter; put on 410 bushels manure broadcast. This manure consisted principally of pine straw and oak leaves, pretty well trampled in the hog pen, but not well rotted. March 10, had 320 bushels mud from pond near horse lot spread broadcast. March 11, had 2 cart loads of ashes and shared pine straw from fresh burnt woods, estimated at 100 bushels. March 18, had 220 bushels compost stable manure hauled on to manure in the hill This manure consisted of stable manure, weeds, leached ashes and pine straw, penned in July last, and watered from ditch in horse lot. Not well decomposed, owing to its being put up too dry. March 25, checked off the ground 3 by 4 feet 10 inches. Put a shovel full of the above manure in each check; covered it the wide way with a list turning plow. March 29 and 30, poured over it the contents of ditch, quantity unknown, but made the ground quite moist. The contents of the ditch were made up of drainings from horse lot, and dead animals covered with pond mud, and at the time of its application, undergoing fermentation freely. April 6, split the list with a small cotton scooter and put a single handful of unleached ashes in each check; after which I put about thirty cluster cotton seed in each check, and covered with the foot. The seed were rolled in ashes. The cotton sprouted quickly and came up well. As soon as the fifth leaf began to make its appearance, it began to die, until it was knee high. I continued to re-plant until 1st June, and then transplanted 3 or 400 stalks, about one-third of which lived but did not do well. I think every fifth hill is missing. It suffered excessively with lice. May 1, plowed with a scooter, colter following pretty deep; scraped round the cotton with a hoe, thinning it out to four or five stalks. May 12, plowed with a sweeper, followed by a hoe, thinning to 3 stalks, dirting it slightly with a hoe. May 29, swept it over again lightly, followed by a hoe. June 16, gave it a slight sweeping, followed by a hoe. July 1, chopped it over lightly broadcast with the hoe. July 17, gave it another light hoeing broadcast, for the last time. August 15, commenced picking. November 1, finished picking. Product 2037 lbs. R. P. SASNETT.

Sparta, Dec. 30, 1844.

REPORT of the Culture and Product of one and one-third Acres of Land in Cotton, by BENJ. T. HARRIS, in 1844.

Land high, dry and thirsty; mixture of long-leaved pine and oak timber; a part very stony; in cultivation the fifth year; amount of land, one and one-third acres. The quantity of manure applied not accurately known, as it was hauled on the land, before it was designed for a premium crop; amount estimated at 25 cart loads, drawn by a single team of oxen. Quality of manure, a mixture of stable and lot, well decomposed; spread broadcast, on 12th and 13th April. Bedded immediately with scooter in the old row, being in cotton previous year; 3 feet 9 inches asunder. Cotton of the variety called cluster. Planted on 15th April, by opening a small furrow with a scooter, the seed strewed moderately thick and covered with a board. May 9, sided with a small scooter with a guard board attached, and plowed the middles with a large scooter. May 13, chopped over, leaving from 1 to 3 stalks 15 to 16 inches apart, and dirted slightly. May 18, swept over with common sweeper. June 5, sided with scooter; plowed the remainder of the row with sweeps. June 12, hoed again and thinned to one stalk generally. In my absence from home, it received a sweeping and hoeing, the date of which I am not able to give—it was not noted. July 26, swept over and hoed again, for the last time. 2291 lbs. on the whole; product per acre, 1728¾ lbs.

Remarks.—The above lot was worked at such times as it was needed. The several operations being conducted in the usual mode.

Sparta, Dec. 31, 1844. BENJ. T. HARRIS.

REPORT of the Tillage and Product of one Acre of Land in Cotton, by R. S. HARDWICK, in 1844

The land light, gray soil, old and quite thin; not able, without manure, to produce more than 300 lbs. of cotton per acre. Plowed in the ordinary way, and with ordinary culture. The crop was planted on the Cloud plan, in part. The land was broken up in January with the colter, running very deep. It was immediately cross-plowed with the turning plow, followed in the track by a colter, partially doing what is called subsoiling. The land was then laid off 5 feet one way and 3 feet the other, with a scooter, followed by a double turner, which opened the furrows deep and well. There was then deposited in each check, one half gallon manure, (no manure spread broadcast,) well rotted stable manure. After it was deposited, it was bedded on, by running two turning plow furrows on each side of the furrows the wide way, leaving a small part of the middle unplowed.

The rains that fell between this operation and planting, so obliterated my furrows the 3 feet way, that I was unable to check off as Cloud directs. I was therefore driven to the necessity of opening my beds in the usual way, and drilling my seed and covering with a board. This operation was the 10th April. The first operation was with the hoe, which was simply chopping about the cotton to break the crust, to keep the cotton from dying. About this time the balks that were left in bedding the land, were plowed with a turning plow; this operation was early in May. In some 12 or 14 days, the cotton having taken a rapid growth, the places where the manure was deposited were clearly indicated by the growth of the cotton. It was then plowed with a sweeper and chopped out, leaving one stalk in a place. In about three weeks, it was plowed deep and close with a scooter, followed by a hoe, and slightly wed. In about three weeks, the sweeper was again run through it, followed by a hoe. After this, say in three or four weeks, the hoes went through it, and chopped what grass there was without attempting to draw any dirt to the cotton.

The product was 1600 lbs. per acre.

In this report, it will be observed, that no manure was used broadcast, and only one half gallon applied to the hill, which took, on the acre, 183¼ bushels. It will be also seen, that in my judgment, the land without manure, and with the common culture, would not have produced over 300 lbs. per acre. Therefore, for the trouble and expense of applying 183 bushels of manure, with the change in the method, which really amounted to but very little more labor, if any. I have increased my crop 1300 lbs. per acre. This amount, at the now low price of cotton, would be worth $20; therefore 183 bushels of manure, with the trouble and labor of applying it, is worth $20.

RICHARD S. HARDWICK.

Sparta, Dec. 31, 1844.

A DISCOVERY.—Capt. Pittman, of the brig Star, which arrived at New York on Thursday, from Grenada, says that he has discovered a method of ascertaining longitude without the use of a chronometer. Unless we are mistaken the British Government many years since offered a handsome reward for such a discovery.

From the Massachusetts Plowman.

MANAGEMENT OF THE HORSE.

This noble animal is an indispensable servant and companion of the farmer. He plows, he harrows, he carts over the farm. He goes to market, to mill, and to meeting; he also accompanies his master to election frolics, political gatherings, and winter sleigh rides, and his company is as much sought after, at such times, as the orator's or the fiddler's.

The horse is more often abused than any of our domestic brutes. He is too generous to spare his limbs or his wind when we are in haste, and his generous ambition too often causes his ruin.

On the farm, however, the horse is not so generally over-driven as on the highway, when we attempt to outstrip the wind, and leave steam engines behind. It is fast driving and subsequent neglect that bring on sprained joints, broken lungs and premature old age.

Horses that are worked on a farm and well attended to will often be good in harness at 25 years of age; while those that travel in stages are not expected to last longer, on the average, than six or seven years. They are then turned off to the farmer to serve in better business, or are sold to the tanner for what the skin is worth.

We have thrown out a few hints, in a former number, on the subject of horse-breaking. We hold that any horse, with proper breaking, may be made to draw as sure as an ox. The horse requires different treatment, because he knows more. And this circumstance makes it absolutely necessary that his driver should be wiser than the driver of an ox. We cannot vouch for the saying of the Irishman, "that a horse knows as much as a man according to his bigness." Still we conjecture that some horses have more understanding than some men have.

HOW TO TREAT HORSES ON A JOURNEY.

Much judgment is requisite to keep a horse in good trim on a long journey, and when your jaunt is but 20 miles, it is worth your while to look well to your horse. The first step is to fit the horse for the journey. If he has been kept out at pasture, he should be taken up and put to hay and grain for a number of days before starting. Hay and grain must be his food while he labors hard; but when you first commence giving grain you must limit the quantity. When he has become used to eating grain, you can make that his principal food on a journey; and this you will find cheaper than any other food.

We have known farmers, of very good sense in other matters, act most absurdly in the management of a horse. They will give "Dobbin" a mess of grain just before starting in the morning—though he has not been used to eating it before—just as if half a peck of oats or corn, crammed down hastily, would aid him in his journey. Dobbin would perform much better through the day without a mouthful of grain. Even one that has been long used to it should never have his stomach stuffed full of it just before starting.

Your most hearty food should all be given at night, unless you have ostlers that can be depended on to feed them two or three hours before morning; in such case a part of your grain may be given at night, soon after you stop, and the remainder two hours at least before you renew your journey.

We are aware that some overwise teamsters will argue, that if you give your horse his grain at night he will eat no hay of consequence, and that you will throw away the money you pay for hay feeding. They therefore endeavor to stuff in as much hay as possible at first, and give the more palatable food for a dessert or stuffer. This is most unwise on two accounts—your horse needs his most hearty food soon after his day's work is over—and very hearty food hurts him when fed just before his work commences.

If the grain is given at night, your horse soon eats enough to cloy him sufficiently to induce sleep and rest; but if he must have poor picking for some hours after being put up, his time of sleep and rest is delayed. It may require the whole night, on fodder that he must pick over, to satisfy the craving of his appetite.

If you are used to travelling, you know you cannot always be sure of the best of hay for your horse. In New York the Dutch tavern keeper advises you to feed with *his latest cut hay*. He argues that more heart is found in this than in what is cut while in full blossom. Well, give a knowing horse such hay and he will stare you in the face and whinnow for grain.

We have travelled much, and on long journeys—we have learned from long experience that grain must be our chief reliance for horse food—that the horse wants something substantial soon after being put up—that his grain then benefits him much more than at any other time, because he is then most in want of it, and because it then has time enough to digest and go into the system.

The best mode is to rely chiefly on grain. One peck of good corn is equal to two pecks of oats, but as your hay may not be good, prefer turning down half a bushel of oats before your horse, soon after putting him up at night. He must have something to fill his stomach, and as the hay may be worthless, your oats will answer for hay and grain too. Your horse will now soon eat as much as he wants—he will soon lie down to rest and to sleep; and before morning his grain will all be converted into good chyle and will be nourishing his blood.

The next morning your horse will be ready to start before you wake up. Instead of waiting for him to eat a new mess of grain, and then to let it digest, you find him plump and good natured, and asking for nothing but your company.

It is well known that horses are often ruined by eating grain at improper times. Farmers have fancied that eating it while the animal is hot with exercise is the principal cause of injury from grain; but it is not so. We have known many horses to die suddenly on eating grain, but never on account of eating it soon *after* stopping. It is rapid driving—violent exercise soon after eating the most hearty kind of food, that is so destructive to travelling horses. There is no more danger in giving a horse the most hearty food in ten minutes after he stops, than in giving a man his most hearty meal as soon as he quits mowing in a hot day.

Let any one consult his own feelings and he may rid himself of the delusion that eating after violent exercise injures him more than at other times. It is violent exercise immediately after eating, before the food has had time to change, that deranges the whole system and causes death. If any traveller objects to the *cost* of feeding on grain while on a journey, we answer that you pay no more for half a bushel of oats than for half a peck—for if you order half a bushel, you buy at wholesale, and your landlord will charge you nothing for the hay. Suppose you pay double the wholesale price for oats, your horse keeping is then but fifty cents, in any country town in New England. And if you call for half a peck of oats, with hay, you will find your bill not far short of that sum.

STAGE HORSES.

These may be kept in a different manner from those that are on long journeys. They are always kept *at home*, and their tenders have leisure enough to prepare their food for them.

Grain is the principal food of stage horses, but it is found economical to mix up cheap substances with it to distend the stomach and to keep the horse in health. Cut straw, or cheap hay, mixed with Indian meal is found to be excellent food for hard laboring horses; and as drivers have leisure enough to prepare it, this has now become the common food of such teams.

Thirty years ago it was the practice of drivers to give their horses meal and water on stopping for a few minutes to take breath. In hot weather it was no uncommon case to see a horse drop suddenly dead in the street. On opening the stomach raw meal was found in cakes. The violent exercise to which these horses are subject gives no time for the rich food to change. The horse cannot vomit, as a man and some other animals can, and he dies with a load on his stomach which he has no means to remove.

Show us one case where a horse has been injured by eating while warm and we will show you a hundred where he has died in consequence of travelling immediately after eating grain. You have all eat hearty meals immediately after labor, and while in a state of perspiration, without injury. And you have all felt pain, on using violent exercise immediately after eating. Judge of the horse as of yourself, and you will judge rightly.

DIFFERENT MODES OF DRIVING.

There are at least two modes of driving horses on a journey. The most important consideration is to take all due advantage of the *momentum*, or *acquired motion*, which your team has got up. You see it requires much more power to start a train of cars than to keep it in motion when under way. So when you move a tub of water on a dray, you find the water inclined to stand still, though your tub moves onward; but the water soon acquires the motion of the tub, and if you keep your tub moving steadily the water will need no more spurring.

When your team has once set the load in motion it should be regularly kept in motion as long as your momentum lasts. Set a planet in motion, and it continues in motion, for there is nothing to obstruct it. But bodies moving on another body are held to it by attraction, and any acquired motion is soon overcome by it. On descending a hill you acquire momentum with but little effort, and one important point, in driving, is to make as much as possible of this power—keep it in use as long as you can.

A good driver will never lose the power that his carriage has acquired in descending a hill, till it has been fairly overcome by friction, caused by the attraction that is found in all bodies. The momentum thus acquired may carry him across a plain, or part way up the next hill; he should therefore be careful not to check this motion in the least degree; but by keeping his team along out of its way, and making them favor rather than check it, he will lose none of its force.

But you find thoughtless drivers continually disregarding this obvious principle. They will come to a walk while the carriage has not yet forgotten its good will to move. The team, instead of favoring the good will of the carriage, is found hanging by the breaching. To compensate for this total loss, the driver finds it necessary to renew the momentum, and he will often do it by whipping his team while raising the next hill! Folly, folly. Your team must have time to breathe, and the best time is while walking up hill. But the team should never be required to get up a great degree of momentum on rising ground.

☞ The Editor of the Alabama Journal has been presented with a novel vegetable of the cabbage kind, raised by E. A. Holt, from seed sent to him from Belgium, by the Hon. H. W. Hilliard. This vegetable is about the size of a small hen's egg, and is a perfect cabbage, firm and white; it is said to be a most delicate dish, and superior to any of the same family of plants. The seeds were sown in May, and transplanted in August as other cabbage plants are, each plant producing from thirty to forty of these beautiful little cabbage heads.

☞ An establishment for the manufacture of various articles of silk is now in active operation at Louisville. The Louisville Journal says—"Most of the operations in this factory are effected by steam. The cocoons are reeled on the machine universally known as the Piedmontese ree', and the silk is spun on a throstle machine, a modification of which makes the twisted silk. Three looms are worked, and are principally employed in making sewing silk, handkerchiefs, vestings, and dress patterns for ladies."

From the American Farmer.

PLASTER AS A MANURE.

If any one were asked, what substance next to *Lime* had produced the greatest melioration in the soil of America, candor would force him to say that Plaster had. It is well known, too, that it has produced quite a revolution in the agriculture of France, England and Germany. But although few have tried it but to experience its benefits, although much of it is used in our country, and the use of it is on the increase, still its use and increase holds no just proportion to what its merits as a fertilizer of the soil would indicate that they should be. For a long series of years the opinion obtained among farmers, to considerable extent, that it was of no utility on lands in the vicinity of salt water rivers; but this opinion, formed from erroneous premises, is pretty generally exploded, if it has not become obsolete. We believe that it sprung, in the first instance, from its use, without obvious beneficial effects, upon the chalk soils of England bordering on the ocean; but the *why* of its inefficiency on such soils was discovered by chemical analyses to arise from the fact that plaster, or the sulphate of lime, abounded in those soils prior to the application; and hence its inertness was directly traced to the fact of its pre-existence in the soil, and not to its proximity to salt water. So it is with salt. This mineral when used on lands too remote from salt water to be effected by the sprays, operates as a good manure, when used either in composts or sown broadcast, but if applied to lands within the range of the influence of salt sprays, it is of no avail, and for the simple reason, that the mineral had already been supplied by another agency. *Lime*, too, if applied to a soil where it already abounded in abundance, would be found to be of no service, as the plants can only take up a certain portion, when held in solution by the rains, and any quantity beyond what is necessary to afford the appropriate supply of stimulus, or nutriment, whichever it may be, or perhaps both, is expletive, and if it do not do harm, can be of no service. Plaster, salt and lime, have each and all, in their turn, been condemned by superficial reasoners, who have drawn their conclusions from isolated cases of experiments, as injudiciously tested as senselessly condemned, and yet the brightest agricultural intelligences of the age, and general experience, concur in the opinion, that when used with discretion, they are all admirable manures. What their specific actions are—whether the one or the other be stimulants, alteratives, promoters of digestion, absorbents, neutralizers, or nutrients, must, to a certain extent, remain as matters of speculation; for even by the aid of the most careful analyses of both them and their products, no settled or well defined opinions can be formed of the peculiar province which they exert, or the *modus operandi* by which their *mysteries* are wrought; for, of a certainty, they do each produce mysteries, as astonishing as those which marked another era of the world.

If we give to a horse, who has already gormandized to his fill, a feed of oats, the probability is, that he will refuse them; but this is no reason why we should condemn that grain as food for horses; neither is it fair to reject plaster, salt or lime, because, when applied to lands where they superabound, they do not manifest their improving properties. If the horse to which the oats were offered had been hungry, he would have devoured them with an admirable relish; so, also, had these minerals been presented to soils in need of them, their good effects would have been apparent.

When we took pen in hand, our intention was, simply to introduce the article which we will subjoin upon "*Gypsum as a Manure;*" but as we have digressed, and in our ramble touched upon *salt* and *lime*, also, we shall quit these, and confine our succeeding remarks to plaster alone.

For a long series of years, plaster was considered merely in the light of a *stimulant*—that it produced the growth of plants in a similar way to that by which alcoholic spirits produced plethora in the human system—by unnatural excitement—and the necessary consequence of this belief led to the opinion, that although the application of plaster produced temporary benefits to a few crops, yet that it ultimately injured lands to which it is long, or in large quantities applied—that the land became plaster-sick. This plaster-sickness, we apprehend, was produced in the same way that gluttons take away their appetites—by over-feeding. This *stimulant theory*, of course, rejected all idea that plaster could be considered in the light of a nutritive manure, and held that it was a mere *exciter*. And in aid of this *view*, the smallness of the quantity used—a bushel to the acre—was adduced, as a proof positive of its beauty and truth. Now, we confess that we have long since rejected this theory as unsound, unsatisfactory and unphilosophic. All analyses have proved, that vegetables, to which plaster had been applied, contained traces of the mineral—some more, some less, but all some. Then, in considering and reflecting upon this fact, the question involuntarily occurred to our mind; if plaster affords no nourishment, how is it, that these plants were enabled to take it up through their feeders, and assimilate in the general mass of their constituent elements. And the only rational answer to which our mind could arrive, was, that if it had not been of that character, it would have been rejected by the plants, and never could have been incorporated so intimately, as all experience proved it had been.

The latter labors of scientific men prove, that it is not only food of itself, but that plaster is a purveyor of food; that by its powers of absorption, attraction and retention, it appropriates to itself from both earth and air, those rare and volatile gases, which form the very nourishment on which plants most delight to feed. Let us hear what *Liebig* says upon this branch of the subject:

"The evident influence of *gypsum* upon the growth of grasses—the striking fertility and luxuriance of a meadow upon which it is strewed—depends only upon its fixing in the soil the ammonia of the atmosphere, which would otherwise be volatalized, with the water which evaporates. The carbonate of ammonia contained in rain water is decomposed by gypsum, in precisely the same manner as in the manufacture of sal ammoniac. Soluble sulphate of ammonia and carbonate of lime are formed; and this salt of ammonia possessing no volatility is consequently retained in the soil. All the gypsum gradually disappears, but its action upon the carbonate of ammonia continues as long as a trace of it exists."

Again:

"It is quite evident, therefore, that the common view concerning the influence of certain salts upon the growth of plants evinces only ignorance of its cause. The action of gypsum really consists in their giving a *fixed* condition to the nitrogen—or ammonia, which is brought into the soil, and which is indispensable for the nutrition of plants."

Plaster, according to Liebig, attracts not only from the atmosphere the ammonia, which is precipitated with the rain and snow, retains it in the earth for the use of the growing plants, but prevents the escape of the same fertilizing gases consequent upon the decomposition of vegetable and animal manures, and feeds them out as they may be needed by the necessities of the plants. By adopting this theory, which is beautiful and more than plausible, we behold the wisdom and mercy of God, in furnishing to man, at a moderate cost, an agent for preventing the waste of the riches of earth and air, that fruitfulness may abound. We say that there is more than plausibleness in this theory—nay, that there is truth in it. Unless its agency extended beyond itself, how else could we account for the astonishing effect produced by the very small quantity of a bushel to the acre—however *stimulative* the carbonate of lime and sulphuric acid may be, of which plaster is composed, unless it composed other powers, it never could exert such potential influence, as it does, upon vegetable growth.

Having premised thus much, we present to our readers the following article, which should command attention:

GYPSUM AS A MANURE.

[We take the following extracts from the pamphlet noticed in our last, from which we copied some rules for the application of guano, by J. H. Sheppard, London.—*N. E. Farmer.*]

Gypsum, or the real sulphate of lime, is considered by all scientific chemists and agriculturist a most powerful agent as manure. I beg to quote an extraordinary instance of its effects, on its first introduction into Norfolk, in 1816. When I was attending Mr. *Coke's* sheep shearing, at Holkham House, and conversing with him in the park, he complained to me that a portion of his estate, near Wells, (about six miles distant,) was a very light sandy land; and, although he treated it in every respect like the rest of his farm, with plenty of manure, he was unable to produce more than six or eight bushels of grain per acre. I recommended him to apply gypsum, and he desired me to forward him ten tons, for a trial. When I again called on him, (three years after,) he said the land before mentioned, *by the application of gypsum*, instead of producing 6 to 8 bushels of grain per acre, averaged 32 bushels of American barley, 36 of Chevalier barley, and 20 of wheat, per statute acre.

I beg further to observe, that gypsum, applied upon light or blow-away sands, in liberal quantities, two or three times, turning over the soil and harrowing in, causes a body, and consequent adherence in the soil, which forms a basis or groundwork, so that it will ultimately retain manures bestowed upon it, which previously were washed into the bowels of the earth, without the least possible benefit to the crops. I can only repeat, that the application of gypsum to sand land, if of genuine quality, and systematically worked into the land, would prove the greatest benefit to the agriculturist.

N. B.—The top-dressing for the fly, and indeed all top-dressings, should be fine gypsum, and applied either between showers of rain or in the early dew of the morning.

Clover.—Of this plant, gypsum is the indispensable, natural and most favorite food, and in which it delights to luxuriate. Upon a measured portion of young clover and other spring seeds, on a light gravelly soil, R. F. Long, Esq., of Bancroft, this year sowed gypsum as a top-dressing, in showery weather, at the rate of five bushels per acre. Comparing the produce and growth of this portion with the remainder of the field, he expresses himself thus: "You have often seen a particular spot where a manure heap has been laid—its thickening and towering above everything around it: now this is exactly what your tenant's gypsum has done."

Oats.—Mr. E. Jefferson, of Low Burnham, drilled in some oats upon a black moory soil, with a compost of ashes, rape-dust and soot. Immediately adjoining the compost oats, six rows were drilled in with gypsum alone, as an experiment. The gypsumed oats were pronounced by all, in less than a month, to be from 30 to 40 per cent. in advance of the compost, and the farmer afterwards informed me that, on harvesting them, they were decidedly the better crop, having stronger straw and larger ears.

Every one extols, and justly so, the manure of the farm yard; yet how few attempt to husband it as they ought. "Far-fetched and dear-bought" as some of our manures are, the farmer continues to buy, whilst he daily witnesses under his own nose the loss of most valuable manure. Ammonia is constantly rising from the stalls and dung-heaps which might be *fixed* by gypsum. The urine is allowed to run anywhere but into reservoirs or tanks, and is soon dried up and lost.

Ill temper puts as many briefs into the lawyer's bag as injustice.

See that what is learned is learned perfectly.

HORTICULTURAL OUTLINE.

AN OUTLINE of the first principles of HORTICULTURE, by JOHN LINDLEY, F R. S. &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.

PREFACE.

It has long been thought by intelligent men, that it would tend essentially to the advancement of Horticulture, if the physiological principles upon which its operations depend for their success, were reduced to a series of simple laws, that could be readily borne in mind by those who might not be willing to occupy themselves with the study, in detail, of the complicated phenomena of Vegetable life.

The importance of these laws is so great, that there is not a single practice of the gardener, the farmer, or the forester, the reason of which, if it relates to the Vegetable Kingdom, can be understood without a knowledge of them.

It has happened, indeed, that many very interesting facts in Horticulture, Agriculture, and Arboriculture, have been discovered fortuitously; and that improvements in them still continue to be occasionally the result of accident, but it cannot be doubted that these discoveries or improvements would have been long anticipated, had the exact nature of the laws from which they necessarily result, been earlier understood.

There can, moreover, be but little mental interest in watching the success of operations of which the reasons are unknown, compared with that which must be felt, when all the phenomena attendant upon practice can be foreseen, their results anticipated, or the causes of failure exactly appreciated.

It must also be manifest, that, however skilful any person may become by mere force of habit, and by following certain prescribed rules, which experience has, or seems to have sanctioned; yet that much more success might be expected, if he acted upon certain fixed principles, the truth of which has been well ascertained, instead of following empirical prescriptions, the reason of which he cannot understand.

It is not, however, to be understood, from this last observation, that rules of cultivation are to be neglected because they cannot be physiologically explained. On the contrary, the mere fact of a given mode of culture having been followed for a length of time by persons deeply interested in the success of their operations, and of much experience, ought to give it very great authority; for it is well known that there are many important facts, the reason of which is either extremely obscure, or altogether unintelligible. This may be owing either to the defective state of our knowledge of the exact nature of many of the phenomena of life, or to the great difficulty of appreciating every circumstance connected with the fact in question, or to constitutional idiosyncrasy, from exceptions to the ordinary laws of nature, and baffle all philosophy.

It is in the writings of Vegetable Physiologists that is to be found what is known of the relation of Botany to the cultivation of Plants; but it is always so mixed up with other matter, that an ordinary reader is unable to tell what bears upon Horticulture and what upon other subjects. I am not aware that there is at present, in any language, a work exclusively designed to separate that part of Vegetable physiology, which relates to the Science of Cultivation, from what appertains to pure Botany, or to other subjects; nor can I learn that such an undertaking is in contemplation.

I am, therefore, induced to lay the following little work before the public; first, by a persuasion that it is better that the attempt should be made imperfectly, than not made at all; and, secondly, by the very favorable reception that has been given to a few hasty ideas upon this subject, which I ventured to sketch out for a work published some months ago.

The following propositions are prepared upon the same plan as those of an elementary work upon Botany originally drawn up for the use of the Botanical class in the University of London.

A similar object has here also been kept in view. My intention has not been to write a work on the philosophy of Horticulture; but simply to point out in the briefest manner, consistent with clearness, what the fundamental principles of that Philosophy have been ascertained to be.

The application of these principles has been necessarily, in all cases, very concise; but there will be no disadvantage if the work acts as an exercise of the reasoning powers, as well as a guide to practice.

It may, perhaps, be thought that several points have been omitted, which it would have been desirable to introduce, such as the influence upon vegetation of electricity, manures, pruning, training, and the various modes of grafting.

But it is possible that a little consideration may show that these subjects do not strictly come within the scope of the following pages.

In the first place, a distinction must be drawn between the *Art* and the *Science* of Horticulture; the former teaches the manner, the latter the reasons of cultivation; and it is to the latter only that these propositions apply. Secondly, the plan of this sketch excludes everything that is merely speculative, or that is incapable of being reduced within certain fixed principles.

Electricity is a power of which we know almost nothing certain, with reference to vegetation; if many things have been written about it, it must be admitted, at least, that very little has been improved.

The same may be said of manures; the theory of their action is explained at paragraphs 19, 262, and 266.

Pruning and training are a part of the *art* of cultivation, dependent upon a great variety of physiological laws, the brief explanation of which is the object of this work. A few hints upon the subject will, however, be found in chapters III, IV, VI, and VIII.

The various modes of grafting are also a part of the *art* of Horticulture; and are deduced from laws explained in the XIVth chapter.

To conclude; the reader should above all things bear in mind that he ought not form his opinion upon any point from the mere consideration of one or two isolated propositions, but of the whole of the phenomena which it is the object of the following pages to explain. For he will find that the vital actions of plants are so dependent upon each other, and of so complicated a nature, that, while the whole can only be understood by a study of the parts, neither can any of the parts be exactly understood, without a knowledge of the whole.

(To be continued.)

SUBSOIL PLOW AND PLOWING.

Allow me for a moment to ask your attention to the *subsoil plow*, with which I presume you are but little, if any acquainted. Although known for years in Europe, and in some parts of our own country, I am not aware that it has been much used in this county. It is made to follow in the furrow directly after the common surface plow, loosening and moving the earth to the depth of six or eight inches below the first furrow, without bringing any part of it to the surface. The advantage to be derived from such loosening is, that the superabundant moisture settles down to the bottom of the furrow, and there is a constant operation of the atmosphere, which gradually converts it into productive soil. It thus produces all the benefits of deep plowing, without the disadvantage of the admixture of an undue proportion of unproductive ingredients in the soil. The soil thus moved will afford space for the extension of the roots or fibres of the plants, so that in seasons of drought they will be less likely to fail. And the ultimate consequence will be, if the land is properly manured, an additional depth to the soil,—say instead of 6 or 7 inches, there will be found 10 or 12 inches. For root crops, and many others, such an alteration must be of great value. Where this process of subsoil plowing has been tried for a number of years successively, and the subsoil has been gradually mixing with the upper soil, the whole has been found so completely changed as to be capable of producing crops that could not before have been cultivated to any advantage.

Mr. Phinney, of Lexington, to whom the agricultural community are under great obligations for his numerous and well conducted experiments, particularly those in the management of grass lands, first brought the subsoil plows into use in this vicinity, about three or four years since. The pattern then used has been much improved by different manufacturers —some specimens of which have this day been exhibited and tried. Mr. Phinney, who has used this plow on many acres of his own farm, informed me that the productive quality of his soil, for many crops, had been increased fifty per cent. by its use. On a question of practical cultivation, there is no man's opinion more worthy of regard.—*Mr. Proctor's Address.*

[The following note is appended to the above:]

In a recent letter received from Mr. Phinney, he says: "I have used the subsoil plow some three or four years, and such is the estimate in which I hold this important implement, that I should consider it a great piece of improvidence to put in a crop without first subsoiling the ground. The character of our *soil* and *climate* are both such, being subject to the extremes of wet and dry, as to render the use of the subsoil plow of more essential benefit here than in England, and if *one-half* the effects from its use, said to be produced in that country, are realized here, no farmer should be without a subsoil plow. The substratum with us, is either hard gravel or clay. Both are greatly benefitted by the use of this plow. In case of too much wet, the redundancy of water is absorbed by loosening the subsoil—when too dry, the plants can find support by being enabled to extend their roots deeper in search of moisture. Our crops, particularly our potatoes and other *root* crops, as they are called, often suffer from droughts that almost invariably occur in our climate in August or September. A failure of these crops is oftener owing to this than any other cause. Without resorting to the test of experiment, can any rational farmer doubt that this obstacle to the productiveness of our soil, may be, in a great measure, overcome by loosening the subsoil. In our old fields, which have been cultivated for many years, with the use of no other than the common plow, an *under crust* has been formed by the travelling of the oxen and movement of the plow for a long time, at a few inches below the surface. This is generally so hard as to be impenetrable by the roots of plants, and hence the necessity of breaking this crust by the subsoil plow. A soil having close and hard gravel, or a stiff clay bottom, may perhaps derive equal benefit from the use of the subsoil plow. Most of my observations, with regard to its beneficial effects have been upon the former, having but little land with a clay bottom. The objections to deep plowing that exist in the minds of some farmers, cannot apply to subsoil plowing, inasmuch as the poorer part of the soil is loosened, but not brought to the surface."

GUINEA GOOSE.—This is the largest of the goose tribe which has fallen under our notice; it is of the size of the swan, and it often weighs more than 25 pounds. We have now in our possession one pair which we purchased for a gentleman in South Carolina, which will weigh in common ordinary condition, over 20 pounds each. We once owned a gander that weighed 24 pounds. They are a noble bird, quite ornamental about the premises, and add much to the scenery, particularly if a sheet of water be near. When floating on its surface they have a stately majestic appearance, and in their movements they much resemble the swan. They have a low, hollow, coarse voice, unlike that of any other variety.—*Bement's Poulterer's Comp.*

THE WORK GOES BRAVELY ON.—Among the many evidences of the spirit that now animates the citizens of Georgia we copy the following notice from the "*Little Georgian*," published in Forsyth, Monroe County.

Remedy for 'Hard Times!'—The enterprising citizens of Monroe are requested to convene at the court-house in Forsyth on the first Tuesday in February next, for the purpose of forming a Cotton Manufacturing Company, to erect a Factory at Towaliga Falls. All who feel an interest in the enterprise will do well to attend promptly.

CONTENTS OF THIS NUMBER.

The Southern Cultivator.

PUBLISHED ON THE FIRST OF EVERY MONTH
BY J. W. & W. S. JONES.

Edited by JAMES CAMAK, Esq., of Athens, Ga.

TERMS.

1 copy one year.....$ 1 00
6 copies " " 5 00
25 " " " 20 00
100 " " " 75 00

The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞ POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS MUST BE POST PAID and addressed to JAMES CAMAK, Esq. Athens, Georgia.

☞ *All subscriptions to commence with the volume.*

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., MARCH, 1845. No. 3.

Culture and Water-Rotting of Hemp.

To the Editors of the Tennessee State Agriculturist:

On a late visit to Missouri, the great hemp region of the West, I had the pleasure to meet with David Myerle, Esq., the author of the enclosed treatise on the *culture and water-rotting of Hemp*. His attention, for some years, as a Government agent, and with a view to its use by our own Navy, has been elicited to this subject; and by inserting his treatise in your paper, you will no doubt render a service to many of your readers. Very respectfully,

Nashville, June 14, 1844. JNO. M. BASS.

WASHINGTON CITY, Jan. 8, 1844.

Sir:—The following Treatise on the Culture of Hemp and Water-rotting, is submitted to the farmers of Missouri and the adjoining States:

The land best adapted to the culture of hemp, is that which has been timbered with black walnut, buckeye, hackberry, and a reasonable proportion of white oak; or rich bottom lands answer well. The land should be plowed deep, and well harrowed before seeding. If sod land, it should be plowed down in the fall to receive the winter frosts; and when time for seeding, (which is from the 1st of April to the 10th of May,) it should be well plowed, harrowed, levelled and smoothed.

The seed should be sown broad-cast, one bushel and a half to the acre. When the blossoms begin to fall, (which is from the middle of July to the 1st of August,) it should then be cut. Hemp left standing too long, injures the staple, and produces a harshness and weakness. It should be cut before it is ripe, which is before the blossoms begin to fall. By attending to this, particularly, you will find the lint heavier, as it will retain its oily substance, (what is termed essential oil,) which, by being left standing until ripe, the action of the atmosphere, as it ripens, causes to leave it, which produces a lightness and harshness in the lint, and deprives it, in a certain degree, of its elasticity; consequently, when the hemp is applied to the hatchel, the staple breaks into small fibres, which are converted into tow, and when the tar is applied to it, and converted into cordage, it becomes stubborn and brittle in frosty weather, and consequently not so durable. Any chemical process, or any other mode to produce a rapid solution of the gum, extracts the oil, weakens the staple, and produces the former injurious effects.

The instrument for cutting is similar to the point of an ordinary scythe; it is about two feet long from the point, with a socket standing at right angles with the face of the blade, and angling to the edge to prevent the person when cutting from bending too much, as it is necessary for him to stand upright as much as possible, to keep the hemp from tangling. The hemp should be cut as close to the ground as possible, and, for watering, it should have the tops cut off as far as the seed ends, and thrown in the shade or kiln dried. The drying in the shade retains its natural color, and causes the essential oil to be retained. The kiln drying has the same effect, but a more rapid process. The sun produces a harshness when rotted, and the dew discolors it, and produces less weight. Pulling hemp is not recommendable; it injures the soil as well as the quality of the hemp—more particularly that of water-rotted. When cutting, all the large hemp should be laid to itself; it should be bound up into bundles with two bands on them, about the size of six or eight inches through in the butts. When too large, they are awkward to handle, which wastes the hemp. Also, place sticks in the centre of each bundle, about one inch in thickness, or more; it prevents the hemp from breaking and tangling, when rotted, and will assist to facilitate the workmen in handling it—the same sticks will answer for a whole crop. If your pools are prepared, commence filling them, and be particular in selecting the size of hemp, placing the large in a pool by itself, and the small also in a pool by itself, as the large undergoes a more rapid solution when immersed. The hemp placed in the pools should be carefully packed down with narrow plank laid on the points and butts, and with rock or timber to weigh it down; rock is preferable.

No hemp less than 5 feet should be water-rotted. Sizes under this may be dew-rotted. It depends upon the temperature of the weather in what length of time it produces maceration. In the month of August it takes 4 or 5 days; September, 6 to 8; October, 10 to 12; December, 3 to 4 weeks. After the 4th or 5th day in August and September, the 6th or 8th day in October and November, and the 3d week in December, or less time, it should be carefully examined, to ascertain when it has fully come to its solution. You will discover that the stalk has a roughness on the surface previous to its being placed in the pools. When the solution has arrived to its extent, by drawing a few stalks out of the bundles in the centre, promiscuously, and passing your hand along the stalk, you will find the roughness has left it, and that it is smooth to the touch. The hemp is then finished; take it out immediately; spread it on the ground, and when perfectly dry on one side, turn it over for the other—say two or three times, until you find that the pith has hardened. If it should receive several rains, it does not injure, provided you attend to turning it. The rains wash off the gum which lies on the surface of the lint, and when applied to the brake, it produces a clearer staple, cleans easier, and makes less tow.

There is also another mode, when the stalk will break off short, and free itself of the lint; but the former is the most certain. The hemp as it is dried, should be thrown into shocks or ricks well secured from the weather penetrating their centre. If the weather penetrates the centre, it will injure the staple by reducing its strength. In breaking the hemp, it should be broke in small hands, about one-third of the ordinary size. In all my experience, I find our hemp requires to be properly hatcheled, to stand the test the Government requires. This is entirely owing to the different mode of handling the Russia hemp; but by breaking in small hands, it relieves itself of sheaves, and produces less tow, and comes nearer to the quality of Russia Riga Rhine, which quality of hemp the Government uses for the Navy. It should not be applied to the brake too often, nor the breakers suffered to practice the habit of breaking dew-rotted hemp, by beating it over the brake to relieve it of the herds. It should be thrown up loosely into the atmosphere, to let the air pass through it. In drawing your hemp, you should draw it from each end, so that the staple will draw clear and have an even hand. See particularly that the butts of the staple be even, and that all the drawings be handed to itself, and not placed in the prime hemp, as it is the habit of doing in dew-rotted. All hemp with the drawings secreted in the centre, will not pass inspection. The hemp must be perfectly clear of sheaves, and that must be effected not by little breaking and beating across the brake, but by plenty of shaking. I have had the strongest evidence, in all my operations, that hemp broke in small hands, say ten or twelve stalks at a time, will yield less tow in hatcheling by 20 to 30 per cent., if the hemp is properly rotted. Also scutcheling helps the hemp greatly, and causes it to yield less tow, and straightens out the staple.

This process is very indispensable to produce a merchantable article. The instrument for scutcheling is a flat wooden or iron knife in the form of a paddle. The hemp is placed on a board upright, about four feet long; one-half of the length of the hemp is held by the left hand at the top of the board, and the right applies the knife, which, when properly applied, relieves the hemp of the small sheaves which adhere to it, and strengthens the staple for the hatchel, which adds greatly to the value of the article, and consequently produces less tow.

If the farmer has a desire to arrive at that stage in their staple to be equal to Russia, it is indispensable for them to adhere to these instructions. There is no more labor attending water-rotted hemp, if properly prepared for operation, than dew-rotted. Hemp water-rotted judiciously, and handled properly, will gain from 10 to 15 lbs. on the hundred on the dew-rotted, which more than amply pays for the difference of labor or expense in preparation. This has been proven to be the fact by those who have tested it at one of my pools in Kentucky, and also by an experienced farmer in Missouri. Hemp that is darkened by the dews, or colored water, which is produced by the blackness of the soil, will not meet with a favorable demand in the eastern market; it partakes of the character and price of dew-rotted hemp. To avoid this, immediately after your hemp is cut, place it under shelter, or shield it with inferior hemp, that the dews or rains will not affect it; and also let your pools be made of plank, or otherwise place them at the side of the stream, and dam it sufficient in height, that, in case the stream should be disturbed by rain or freshet, it does not pass through your pool.

The construction of Pools is as follows: Small spring branches dug down two or three feet; a levee thrown up around them, and small flood-gates at each end, made simply out of four pieces of boards, a foot wide and two feet long. A waste gate around them to let the water pass around, and not into the pool; if so, it produces an uneven temperature of the water, and the hemp becomes irregular in its solution. The pools can be made of plank; and the water pumped into them, supplied through a small leaden pipe by an ordinary lifting pump. A pool 40 by 60 feet, 2½ feet deep, will receive 3 to 4 acres of ordinary hemp. The pools must not be over 3 feet deep; it will produce an irregular solution, owing to the uneven temperature of the water. To water-rot in ponds or large streams, is not so commendable; particularly running streams. The hemp becomes irregular in its solution, and loses its lint. The preparation necessary is to have two saplings; pin them at each end with cross-bars, forming a raft, with uprights at each end; their length to be the depth of the water. These form a raft,

say 20 or 30 feet long; load your hemp on them, and sink them with rock. For the conveyance of water to and from your pools, I will call your attention to the leaden pipes manufactured in this city by Mr. W. W. Thompson. These pipes will be a great acquisition for this purpose, as also for watering stock and avoiding waste of water. They can be made any length, and at a much cheaper rate than an ordinary spout. To those persons who are not in possession of springs, they can fix a small lifting pump in any part of their farm, and supply their vats with water.

As regards the process, there need not be the slightest apprehension as to deleterious effects to health. As a demonstration of this fact, in my operations for the Government, I had about two hundred men at the various pools in the hemp-growing region of Kentucky, from 1840 to 1841, in a circuit of 100 miles, and there was not one instance of sickness, although many of the men exposed themselves to the water when it was not necessary. I also advise gentlemen not to attempt to deliver more than one ton of hemp to each laborer they have, and not to exceed from 5 to 10 tons the season: beyond this, it will produce difficulties

I will also observe the necessity of watching your hemp closely when near the time of its full solution. If you permit it to have too much rot, it will injure the hemp seriously in strength and in weight; and to avoid this, to those that are not particularly acquainted with its proper solution, they may take it out before it is carried too far, and spread it down upon the field, for the dews and rains to finish, but at the same time be particular to attend to turning it, that it may receive an equal proportion of rains and dews throughout. Hemp rotted in the spring is not of as good quality as that rotted in the fall, say the months of October, Novemoer, and December. The spring rot produces a lightness of color, and the staple is weakened and loses much in weight. This is produced by the state of the atmosphere, and the sudden and extreme changes of it, as also, the hemp lying in the stack after being a long time cut, undergoes what is termed a sweat, which changes the state of the staple. In all the hemp-growing regions of Russia, the crops amount yearly to 90,000 tons. The best hemp produced is in the Government of Cheiringoff. The hemp is mostly of short staple, and of the very best quality; the produce is about 15,000 tons yearly;—and also in part of the Govern nent of Orel, short staple is produced, and carried to the port of Riga; but the greater part of the hemp produced in this Government is long staple, of which the produce is about 14,000 tons. The hemp of Koursk is mostly of long staple, and the produce is about 13,000 tons. The hemp of the Government of Tooler, is also long staple, and produces about 13,000 tons. In the Governments of Tamboff and Riazan, the produce is about 14,000 tons, but not of good quality, being more after the color of flax, and its staple is weak; it is chiefly produced for the Archangel market, and a portion of it reaches St. Petersburgh. The hemp grown in the Government of Smolenski, is of short staple, partakes of the character of that produced in the Governments of Tamboff and Riazan, and which is mostly manufactured into sail-cloth fabrics; the produce is about 7,000 tons, mostly short staple. The Russian mode practiced in preparing their hemp, differs only with their instruction in relation to the care and pains taken in preparation; a portion of the country also adopts a chemical process to produce a rapid solution of the gum which is injurious to the staple. As this country is subject to frequent hail storms, the crops oftentimes fall short of this.

In laying this information before you, my object is to convey to you the quantity and the various qualities of hemp produced in the hemp growing regions of Russia. You will also notice that we have a decided advantage over the Russian article, in comparing the small quantity of long staple to ours, as all our hemp generally is of long staple; therefore, by assiduous attention to the culture and preparing of it, our staple must and will have the ascendancy in the European market; in a reasonable time, Missouri can supply the whole world with hemp; as well as must Illinois and Iowa arrive to be extensive hemp-growing States, and of a superior quality. And let the agricultural interest of these States buckle on their energies and industry, and consummate it to the advancement of their own prosperity and the country in general.

I have had the assurance recently given me, from a gentleman direct from London, of the highest standing in mercantile transactions, that the moment we are prepared, he will effect a contract to supply the British Government with our hemp for the Navy, which consumes equal to our Navy and our commercial enterprise, about 12,000 tons yearly. Also, the consumption of the port of London is 20,000 tons yearly, embracing the requirements of the Navy. I have also had the assurance, from a gentleman of high standing in commercial transactions in France, that from the character of our hemp, the moment the hemp is prepared, he will effect the supplying of the French Navy with our staple. These countries are desirous to encourage us, that they may have two markets to flee to in case of any warlike disturbance.

I have labored with great sacrifice of interest for these four years, with the pleasing and proud anticipation to see the country independent of this foreign staple, and that we may become heavy exporters; and the day is not far distant, when these anticipations will be fully realized.

And to facilitate this most important object, I have, by the solicitations of a number of gentlemen, delegates from the West, and others in power at this city, consented to embark upon this arduous and hazardous undertaking, with the view of supplying the Navy with American Water-Rotted Hemp, from the West, for a term of years. I do assure you, gentlemen, that no pecuniary inducement could have influenced me to embark upon this work of enterprise again But something must be done to keep alive and finish this great work, which has been commenced, and is in progress to its ultimate accomplishment. I have lost a large fortune in establishing the practicability of it, and have undergone great afflictions, in consequence of which, I have felt reluctance to subject myself to a second trial of the various circumstances which befel me, in effecting that important object. But with a desire to promote *the agricultural interest of the West, and to see my country speedily independent of this foreign staple*, and with the confidence I have in you, that you will support me in this act of enterprise, I now come forward once more with all my resources and energy, to give this subject additional impetus, that will convince the world and the Russian Autocrat, that this Republic can stand free and independent of his staple and fabrics, and can supply the commercial world. To accomplish this great work, I lean upon you, *the farmers of the West*, to rally to my aid, and give me your prompt and energetic co operation. *And to you, enterprising Eastern men, I invite you West*, to establish your ingenuity and enterprise in machinery, for the manufactory of fabrics. Your interest, farmers, your prosperity, and your duty as patriots, and as an example to the rising generation, demand your prompt and undeviating attention to this important subject; in so doing, it acquires all, and will also be a blow struck at the foot of the throne of that Autocrat, which may produce events that will in time give liberty to millions of souls who are suffering under the most degraded bondage of slavery. The question no doubt will arise in your mind, How is all this to be accomplished? I will answer briefly: Let every farmer take four acres of his best land, sow it down in hemp, follow my instructions laid before you, to the letter. If you have no water convenient, build plank vats, 25 feet by 14, and 2½ deep; pump the water into the vats when the hemp is laid in. They require but a small quantity of water; two men can pump sufficient water in a day, and the same water, with a small portion of additional fresh added to it, if necessary, will answer for two or three rottings. This size vat will answer for a crop of 25 or 30 acres, which is more than one farmer should undertake the first year Four acres of good ordinary hemp, judiciously rotted, properly cleaned, scutcheled hatcheled, and well prepared, will yield to the farmer a gain clear of all expense, of $150, or more. What can be a greater encouragement in an agricultural pursuit than this? In addition to this, a steady market, with the assurance that if you produce a prime article, the highest cash price is ready for you, according to its quality, delivered at the various points of Agencies. Those persons wishing to see me, can address me at St Louis, post paid, (*no letter will be taken out of the office, unless post paid.*) I will either wait upon them personally, or answer them from any State that feels a desire to embark in this enterprise I am candid to inform those that have never water-rotted, that there is more labor attending this operation than they imagine. But do not be discouraged; experience and time will overcome it, in a very great degree. With perseverance and industrious attention, not relying on the care and attention of your negroes and laborers, but by your own close attention, you will see great advantages to be gained in the prosecution of this business. I can with confidence and in truth say, that with practical experience and perseverance, they will be found worth all the theory and negroes in existence, in the saving of labor, expense, and the quality of the article produced. They will overcome difficulties and objections which first present themselves to you in its incipiency, which finally become obstacles of *minor consideration*. Therefore be not deterred when they are met. But persevere, and acquaint yourselves of the most practical and economical manner to exercise in the water-rotting process. My plans are laid before you; practice them, and you will improve on them; practice makes perfect, and opens to you advantages that can be applied to great improvements and economy. But throw aside all ideas of humbuggery, such as steam and chemical process.

Hemp for the Navy, must not be less than four feet and a half in length, a clear staple, of proper and natural strength, preserved by judicious treatment, and of a bright color; dark hemp will not be received for that purpose. It will be received and appropriated for commercial enterprise, at a reduced price.

It is the desire, that the farmer will practice the mode of scutcheling to relieve the hemp of the herds, in the place of applying it so often to the brake. It straightens out the staple, and produces much less tow, when applied to the hatchel Also that they should become familiar with hatcheling of hemp generally. It adds greatly to the character of the hemp, east and abroad. And to those that wish to purchase hatchels, they can be obtained at St. Louis for $5 to $6; or any ordinary blacksmith can make them, provided they understand setting the teeth, (it generally depends on this.) If the teeth are not properly set, it will split and derange the staple, and produce much tow. All hemp delivered unhatcheled, will be received and paid for according to quality. It has been the practice to use great deception in the preparation of this article, by secreting the drawings and sheaves in the centre of the hands. But it will be useless to attempt this, as they are sure of being detected.

There are four classes of Russia Hemp: Riga-Rhine, Clean St. Petersburgh, Half clean, and Out-shot. And it is the intention of the undersigned, if employed by the Government, to classify our hemp in like manner, and in that event the price paid will range up to $8 per 112 lbs, delivered at St Louis, for that quality of hemp that will stand the test the Government requires. And that can be effected and produced by judicious rotting, scutcheling, hatcheling, and proper length. That the hemp

may be inspected and selected without prejudice to either party, there will be honest, competent men from the east, who are fully acquainted with the qualities of Russia Hemp, and more particularly that article the Government requires, whose hands it is to pass through before it will be paid for.

I conclude this subject with a conviction that this appeal will not be in vain, and that in three years the foreign article will be entirely excluded from our ports, and heavy exports made to Europe.

And I will impress upon your minds the importance of adhering to these instructions; and when your hemp is ready for market, by calling upon Messrs. W. W. Thompson & Co., of St. Louis, or the subscriber, you can obtain any information in regard to the final disposition.

David Myerle, *St. Louis, Mi.*

Washington City, April 8th, 1844.

The following letter is submitted to the farmers of the West. The hemp named by the Superintendent, was raised by A. G. Porter, of Buchanan County, Missouri. It was carefully preserved (after cutting) from the rains and dews, which discolor it. It was broke in small hands, which causes it to produce less tow. With a subsequent treatment I gave it, it produced this result. Any farmer who will adhere to my instructions can produce the same with as little labor and expense as to do it otherwise.

David Myerle, Saint Louis.

U. S. Ropewalk, April 5th, 1844.

Sir:—Through your politeness I received, on the 2d instant, a copy of your circular to the hemp growers of the Western country, giving them general, and what I should think, very accurate directions for growing and preparing hemp. Your remarks on the drying of hemp in the shade that the essential oil may be retained, I conceive to be of the utmost importance, for since hemp is a vegetable it is of great moment that the oil should be retained in order to prevent its rapid decay.

I think from what I have seen of the American hemp that the most of it has been dried in the sun by its being so very harsh and brittle.

Your remarks on the sorting of it will be of great utility, as I have discovered clean out-shot and half-clean all in the same bale, varying in length from 3 to 6 feet, which of course in hatcheling, a large portion of the hemp will be drawn out as tow, therefore there should be as much uniformity as possible in the length of the heads, by so doing it will be an advantage to the one who sells as well as to the one who buys.

In regard to the hemp raised by Mr. A. G Potter, of the State of Missouri, much credit, as you observe, is certainly due him in the preparation of his hemp, not that the strength is greater than the most of American hemp, but for its being so well cleaned of the wood particles and of the tow, and also for its being of good color and properly packed and uniform in its length, and when the Western hemp is all prepared like it, then there will be no fear of sending it to any market, as it will compete with the Russian in quality and in price

I hope, sir, you will soon see your labors crowned by seeing the American hemp used, not only in this country, but in foreign countries also, which in my opinion will be the case, if proper instructions are strictly adhered to.

Very respectfully, your obed ent servant,

Wm. Cabin, *Superintendent.*

To David Myerle, Esq., Washington, D. C.

Broom Corn.—Large quantities of the brush of broom corn, raised in the valley of the Ohio and elsewhere, have been shipped to England within three months past, together with broom handles, for the purpose of manufacturing the brooms there. By managing in this way, we understand that brooms can be afforded cheaper in Great Britain, than if made here and then exported.

Prepare without delay for a vigorous spring campaign.

From the Southern Agriculturist.

Cultivation and Curing of Cuba Tobacco.

Sir:—The following communication on the Cuba tobacco, is from a gentleman who has had opportunities of becoming thoroughly acquainted with the mode of cultivating and curing the plant as practised in Cuba; and where experience has enabled him to ascertain the modifications necessary to be adopted in transferring the culture to this country. It will be perceived that Gen. Hernandez estimates the value of the tobacco, *in leaf*, at 50 cents per lb.; a higher price than it usually brings in our markets, where it is purchased for the purpose of being used as *wrappers* for segars; the *fillings* of which are generally of American or Virginia tobacco. It is well known, however, that the best tobacco raised in the island is never exported, being reserved for the manufacture of the celebrated Havana segars, after selling, as we have been informed, for more than a dollar a pound. As the tobacco raised and cured here, is considered by judges as no way interior to the best Havana, it would probably sell for even a higher price than that estimated below, were it properly prepared for market according to the Cuba method.

There can be no doubt but that this valuable plant may be easily added to the enriching staples, and other numerous resources that form the *golden fleece of the South.* It is an advantage of this culture that it affords an instance in which the manufacturing and agricultural interests are happily combined, as its highest profits can only be obtained by putting the tobacco into a wrought form, and making it into segars.

The subjoined directions will be found more specific and minute, than any that have before been given to the public, and will, therefore, I hope, prove an acceptable contribution to the pages of the Agriculturist. With respect, your ob't. serv't.,

W. H. Simmons.

COPY OF A LETTER from Jos. M. Hernandez, Esq., to Dr. Wm H. Simmons, dated

Mala-Compra, April 15, 1830.

Dear Sir:—I have delayed this communication on the culture of Cuba tobacco longer than I ought, but as you are acquainted with the multiplicity of engagements that have constantly occupied my attention, I trust that you will excuse me.

The first thing to be considered in this, as in every other culture, is the soil, which for this kind of tobacco ought to be of rich sandy loam, neither too high or too low; that is, ground capable of retaining moisture. The more level the better, and if possible, well protected by margins. The next should be the selection of a spot of ground to make the necessary beds.

It would be preferable to make these on land newly cleared, or at all events when the land has not been seeded with grass; for grass seeds springing up together with the tobacco, would injure it materially, as the grass cannot be removed without disturbing the tobacco plants. In preparing the ground for the nurseries, break it up properly, grub up all the stumps, dig out the roots, and carefully remove them with the hand; this being done, make the beds from three to four inches high, of a reasonable length and from three to three and a half feet broad, so as to enable the hands at arms-length, to weed out the tender young plants with the fingers from both sides of the bed, and keep them perfectly clean.

The months of December and January are the most proper for sowing the seed in this country* —some persons speak of planting it as early as the month of November. I am, however, of opinion that about the latter part of December is the best time to sow tobacco seed; any sooner would expose the plants to suffer from the inclemency of the most severe part of our winter season. Before the seed is sown, take some dry trash and burn it off upon the nursery beds, to destroy insects and grass seeds; then take one ounce of tobacco seed and mix it with about a quart of dry ashes, so as to separate the seed as much as possible, and sow it broadcast. After the seed has been thus sown, the surface of the bed ought to be raked over slightly, and trodden upon by the foot, carrying the whole weight of the body with it, that the ground may at once adhere closely to the seed, and then water it. Should the nursery beds apparently dry from blighting winds or other causes, watering will be absolu ely necessary: for the ground is to be kept in a moist state from the time the seed is planted until the young plants are large enough to be set out.

The nurseries being made, proceed to prepare the land where the tobacco is to be set out. If the land is newly cleared, (and new land is probably more favorable to the production of this plant than it is to that of any other, both as regards quality and quantity,) remove as many of the stumps and roots as possible, and dig up the ground in such a manner as to render the surface perfectly loose; then level the ground, and in this state leave it until the nursery plants have acquired about one-half the growth necessary to admit of their being set out. Then break up the ground a second time in the same manner as at first, as in this way all the small fibres of roots and their rooty parts will be more or less separated, and thus obviate much of that degree of sponginess so common to new land, and which is, in a great measure, the cause of new land seldom producing well the first year, as the soil does not lay close enough to the roots of the plants growing in it; so that a shower of rain produces no other effect than that of removing the earth still more from them. Should the land be such as to admit of being worked with the plow, it ought certainly to be preferred to the common hoe. The plow, however, should be excluded after the plants are set out.

The ground having been prepared and properly levelled off, and the plants sufficiently grown to be taken up, say to the size of good cabbage plants, take advantage of the first wet or cloudy weather to commence setting them out. This should be done with great care, and the plants put single at equal distances; that is about three feet north and south, and two and a half or two and three-fourths feet east and west. They are placed thus close to each other, to prevent the leaves growing too large. The direction of the rows, however, should alter according to the situation of the land, where it has any inclination the widest space should run across it, as the beds will have to be made so as to prevent the soil from being washed from the roots by rain, when bedded; but, where the land is rather level, the three feet rows should be north and south, so as to give to the plants a more full effect on them by passing across the beds, than by crossing them in an oblique direction To set the plants out regularly, take a task line of 105 feet in length, with a pointed stick three feet long at each end of it, then insert a small piece of rag or something else through the line at the distance of two feet and three-fourths from each other, place it north and south, (or as the land may require,) at full length, and then set a plant at every division; carefully keeping the bud of the plant above the surface ground. Then remove the line three feet from the first row, and so on until the planting is completed. Care ought to be taken to prevent the stretching of the line from misplacing the plants. In this way the plants can be easily set out, and a proper direction given to them both ways. In taking the plants up from the nursery, the ground should be first loosened with a flat piece of wood or iron, about an inch broad; then carefully holding the leaves closed towards each other, between the fingers, draw them up and place them in a basket or some other convenient thing, to receive them for planting. After taking up those which can be planted during the day, water the nursery, that the earth may again adhere to the remaining ones. The evening is the best time for setting out the plants, but where a large field has to be cultivated, it will be well to plant both morning and evening. The plants set out in the morning,

* Florida.

unless in rainy or cloudy weather, should be covered immediately, and the same should be done with those planted the evening previous, should the day open with a clear sunshine—the palmetto leaf answers this purpose very well. There should be water convenient to the plants, so as to have them watered morning and evening, until they have taken root.* They should also be closely examined when watered, so as to replace such plants as should happen to die, that the ground may be properly occupied, and that all the plants may ripen as nearly together as possible.

From the time the plants are set out, the earth round them should be occasionally stirred both with the hand and hoe. At first hoe flat, but as soon as the leaves assume a growing disposition, begin gradually to draw a slight bed towards the plant. The plant must be closely examined, even while in the nursery, to destroy the numerous worms that feed upon them; some, by cutting the stalks and knawing the leaves when first set out—these resemble the grub worm, and are to be found near the injured plant under ground; others which come from the eggs deposited on the plant by the butterfly, and feed on the leaf, grow to a very large size and look very ugly, and are commonly called the tobacco worm. There is also a small worm, which attacks the bud of the plant, and which is sure destruction to its further growth; and some again, though less destructive, are to be seen within the two coats of the leaf; feeding, as it were on the juices alone. The worming should be strictly attended to every morning and evening, until the plants are pretty well grown, when every other day will be sufficient. The most proper persons for worming are either boys or girls from ten to fourteen years of age. They should be made to come to the tobacco ground early in the morning, and be led by inducements, (such as giving a trifling reward to those who will bring the most worms,) to worm it properly. Grown persons would find it rather too tedious to stoop to examine the under part of every leaf, and seek the worm under ground; nor would they be so much alive to the value of a spoonful of sugar, or other light reward. Besides, where the former would make this search a matter of profit and pleasure, it would to the latter prove only a tedious and irksome occupation. Here I will observe, that it is for similar reasons that the culture of the Cuba tobacco plant more properly belongs to a white population, for there are few plants requiring more attention and tender treatment than it does. Indeed it will present a sorry appearance, unless the eye of its legitimate proprietor is constantly watching over it.

When the plants have acquired from twelve to fourteen good leaves, and are about knee high, it may be well to begin to top them, by nipping off the bud with the aid of the finger,† taking care not to destroy the small leaves immediately near the bud: for if the land is good and the season favorable, those very small top leaves will in a short time be nearly as large, and ripen as soon as the lower ones, whereby two or four more leaves may be saved; thus obtaining from sixteen to eighteen leaves in the place of twelve or fourteen, which is the general average. As the topping of the tobacco plant is all essential in order to promote the growth, and to equalize the ripening of the leaves, I would observe that this operation should at all events commence the instant that the bud of the plant shows a disposition to go to seed, and be immediately followed by removing the suckers, which it will now put out at every leaf. Indeed the suckers should be removed from the plant as often as they appear.

The tobacco plant ought never to be cut before it comes to full maturity, which is known by the leaves becoming mottled, coarse, and of a thick texture, and gummy to the touch; at which time the end of the leaf, by being doubled, will break short, which it will not do to the same extent when green. It ought not to be cut in wet weather, when the leaves lose their natural gummy substance, so necessary to be preserved. About this period the cultivator is apt to be rendered anxious by the fear of allowing the plants to remain in the field longer than necessary, until experience removes these apprehensions: he should be on his guard, however, not to destroy the quality of his tobacco, by cutting it too soon. When the cutting is to commence, there should be procured a quantity of forked stakes, set upright, with a pole or rider setting on each fork, ready to support the tobacco, and to keep it from the ground. The plant is then cut obliquely even with the surface of the ground, and the person thus employed should strike the lower end of the stalk two or three times with the blunt side of his knife, so as to cause as much of the sand or soil to fall from it as possible; then tying two stalks together, they are gently placed across the riders or poles prepared to receive them. In this state they are allowed to remain in the sun or open air, until the leaves have somewhat wilted, whereby they will not be liable to the injury which they would otherwise receive if they came suddenly in contact with other bodies, when fresh cut. Then place as many plants on each pole or rider as may be conveniently carried, and take them into the drying house, where the tobacco is strung off upon the frames prepared for it, leaving a small space between the two plants, that air may circulate freely among them, and promote their drying. As the drying advances, the stalks are brought closer to each other, so as to make room for those which yet remain to be housed.

In drying the tobacco, all damp air should be excluded, nor ought the drying of it to be precipitated by the admission of high drying winds. This process is to be promoted in the most moderate manner, except in the rainy season, when the sooner the drying is effected the better, for it is a plant easily affected by the changes of the weather, after the drying commences. It is then liable to mildew in damp weather, which is when the leaf changes from its original color to a pale yellow cast, and from this, by parts, to an even brown. When the middle stem is perfectly dry, it can be taken down, and the leaves stripped from the stalk and put in bulk to sweat; that is, to make tobacco of them; for before this process, when a concentration of its better qualities takes place, the leaves are always liable to be affected by the weather, and cannot well be considered as being any thing else than common dry leaves, partaking of the nature of tobacco, but not actually tobacco. The leaves are to be stripped from the stalks in damp or cloudy weather, when they are more easily handled, and the separation of the different qualities rendered also more easy. The good leaves are at this time kept by themselves, for *wrappers* or *caps*, and the most defective ones for *fillings* or *strips*. When the tobacco is put in bulk, the stems of the leaves should all be kept in one direction, to facilitate the tying of them in hanks; afterwards make the bulk two or three feet high, and of a proportionate circumference. To guard against the leaves becoming overheated, and to equalize the fermentation or sweating, after the first twenty-four hours place the outside leaves in the centre, and those of the centre to the outside of the bulk. By doing this once or twice, and taking care to cover the bulk either with sheets or blankets, so as to exclude all air from it, and leaving it in this state for about forty days, it acquires an odor strong enough to produce sneezing, and the other qualities of cured tobacco. The process of curing may then be considered as completed. Then take some of the most injured leaves, but of the best quality, and in proportion to the quality of tobacco made, and place them in clear water, there let them remain until they rot, which they will do in about eight days; then break open your bulks, spread the tobacco with the stems in one direction, and dampen them with this water in a gentle manner, that it may not soak through the leaf; for in this case the leaf would rot.* Then tie them in hanks of from twenty-five to thirty leaves; this being done, spread the plants in the tobacco house for about twelve hours, to air them, that the dampness may be removed, and afterwards pack them in casks or barrels and head them tight, until you wish to manufacture them. The object of dampening the tobacco with this water, is to give it elasticity, to promote its curing free, to increase its fragrance, to give it an aromatic smell, and to keep it always soft. This is the great secret of curing tobacco for segars properly, and for which we are indebted to the people of Cuba, who certainly understand the mode of curing this kind of tobacco better than any other people. It is to them a source of great wealth, and may be made equally so to us. We can have here three cuttings from the original plant—the last cutting will be of rather a weak quality, but which, nevertheless, will be agreeable to those who confine their smoking to weak tobacco.

In ratooning the plant, only one sprout ought to be allowed to grow, and this from those most deeply rooted—all other sprouts ought to be destroyed.

The houses necessary for the curing of tobacco ought to be roomy, with a passage way running through the centre, from one extremity of the building to the other, and pierced on both sides with sufficient number of doors and windows, to make them perfectly airy.

In addition to what I have said respecting the mode of cultivating and treating the tobacco plant, I have further to state, that once the plant is allowed to be checked in its growth, it never again recovers it. That in promoting the drying of the leaf, fire should not be resorted to, because the smoke would impart to it a flavor that would injure that of the tobacco itself.

In order to obtain vigorous plants, the seed ought to be procured from the original stalk, and not from the ratoons, by allowing some of them to go to seed for that express purpose. In Cuba the seed is most generally saved from the ratoon plants, but we should consider that that climate and soil are probably more favorable to the production of this plant than ours, and consequently, we ought to confide in the best seed, which is had from the original stalk.

All plants have their peculiar empire, nevertheless we should not be deterred from planting Cuba tobacco here, for even should we be compelled to import the seed every third year, which would be as often as necessary, it would still prove a profitable culture. Taking 600 lbs., which is the average product per acre, it would yield, (if well cured,) at 50 cents per lb., $300 in the leaf.

The following exhibits the profit to be derived from it when manufactured into segars:

600 lbs., allowing 8 lbs. to 1000, would produce 75,000 segars, which, at $10 per 1000.....	750 00
Cost of the leaf.....300 00	
Worth of manufacture at $2 50 per 1000..187 50—487 50	
Difference in favor of the manufacturer,....$262 50	

This amount being the profits of the manufacturer alone, the profit to him who would combine both pursuits would be more than doubled.

As to the quantity of land which can be cultivated to the hand, there is some difference in the practice of planters; however, I think that I am within the usual calculation in saying, that an acre and a half would not exceed the quantity that an able hand can easily cultivate and manage properly.

I am, with respect, your obd't. serv't.,
JOSEPH M. HERNANDEZ.

N. B.—I have omitted to state the cost of the segar boxes, which of course has also to be deducted. This would vary according to the facility of obtaining materials, but probably would not exceed 25 cents per box.

* It is hence generally necessary that wells should be sunk at convenient distances through the field.

† Washing the hands after this, in water, is necessary as the acrid juices of the plants, otherwise, soon produce a soreness of the fingers.

* Sponge is used in Cuba for this delicate operation.

Speak not unless you can benefit others or yourself; and avoid trifling conversation.

From the So. Ca Temperance Advocate.

Dr. Porcher's Report on Manures.

BLACK OAK AGRICULTURAL SOCIETY, November 19, 1844.

Resolved, That the Report of the Committee on Manures, this day read, be communicated to the State Agricultural Society, to be read before that body.—From the Minutes.

H. W. RAVENEL, Sec'ry.

REPORT.

The Committee on Manures, in pursuance of the Resolution under which they are required, at the fall meeting of the Society, to report, concerning "the best and most economical mode of collecting and preparing manures; the time and manner of their application; the adaptation of certain manures to certain crops, with a detailed account of all experiments on the subject, which have been carefully conducted and the results accurately noted;" beg leave to observe, that the wide range of duty committed to them requires more time than has elapsed since their appointment. Sensible, however, of the vast importance of the subject, they have entered seriously and faithfully into the discharge of their duty, and offer the following as a Report only in part:

It is due, however, to the Society, to premise that the direction which has been given to our labors, is one which can hardly be said to be comprehended in the resolution under which this report is presented. Believing, however, that the points to which we are desirous of drawing the attention of the Society, are of vital importance to our interests, we offer no apology for our apparent deviation from the letter of the chart laid down for our governance.

It is but a very few years since, within the limits of this Society, the benefits of manures were mooted at every social meeting; and even now, though no one is so outwardly heretical as to question their ability, there are yet many who have derived so little practical benefit from their application, that their faith in their efficacy, is rather a confidence in the testimony of others, than the result of their own observation and experience.

Believing firmly as we do, that on the judicious use of manures, depends the prosperity, not only of our Society, but of our State, we have devoted our labors to an investigation of the causes of the failures of manures, and have endeavored, with the aid of our present state of knowledge, to point out the remedies.

The great object of all farmers, both practical and theoretical, has been to accumulate and bestow upon the land a quantity of animal and vegetable matter, in the state of progressive decomposition. This manure, called compost, has been for many years the only sort applied to cotton husbandry in the inland districts. Its value depends upon its origin; that from the stable being always much more highly esteemed than that from the cow-pen. These were the manures universally applied to all soils, whatever their condition. Limited, however, as was the range of our manuring resources, our knowlede of the soil as cultivated, was, and even now is, still more contracted. No idea whatever was entertained of their chemical composition. A brief inquiry into their physical condition was all the investigation bestowed upon them.

A new light has recently dawned upn us; and it becomes us peculiarly as cultivators of products unknown to other portions of Caucasian civilization, to embrace and improve it to the highest possible degree. This light is the thorough application of chemistry to agriculture. The cultivators of other products have for their guides the experience of ages, and of the whole extent of civilization. We stand, as agriculturists, isolated from the mass of mankind; their practice is to us a mystery, their experience to us useless. Let us hail, then, as the opening of a new era in our agriculture, the scientific discoveries which enable us to apply to practical farming the mysteries of the laboratory.

The doctrine of the necessity of furnishing to plants, either as native constituents of the soil on which they are required to grow, or in form of manure, *all* the components, both organic and inorganic, of which they are constituted, and which are necessary to their healthful existence, was first distinctly announced by Liebig, the publication of whose book forms an interesting epoch in the history of agriculture. But whilst announcing the important fact, he seems to have regarded it rather as an axiom, incontrovertible, than as a new truth whose importance was to have been enforced upon the attention of agriculturists. Hence most readers of his work are conscious of no operation of husbandry so important as the collection and supply of nitrogen to plants. Indeed the philosopher seems to snuff ammonia in every breeze. All the pleasing impressions which others derive from the sight of a herd of cattle going to market, are lost to his imagination. He sees in them nothing but a mass of nitrogen unfairly abstracted from its native soil; and when man himself has finished his work and given up the ghost, his only concern is that the nitrogen of his composition is laid down too low to be made available to vegetation.

But let us do justice to Liebig. He is not one-sided in his views. He dwells, it is true, particularly upon one subject, but his love of a theory does not lead him to strain every point to sustain his views. Another class of philosophers have ridden a hobby which they call *geine*, to which they attribute all the virtues of manures. It would be best, we think, before going into the *modus operandi* of manures, to inquire first into the whole condition of the products of the soil,—let us first know what they are, and we shall be unfortunate indeed, if we do not find out what is good for them.

It is one of the blessings wherewith our lot is tempered, that all genuine work, all honest labor, is productive. So we have been benefited by every class of philosophers who have applied their industry to the consideration of agriculture. We are still hampered in our researches after truth, by the obtrusion of their fanciful theories; but a mass of light has been shed on the subject, from which we are confident of deriving vast benefit.

All plants, we may say all vegetable products, are composed of carbon, hydrogen and oxygen; in addition to these, some have nitrogen. Of these constituents, the soil is composed chiefly of carbonaceous matter; the atmosphere we breathe consists of oxygen and nitrogen in a state of mechanical combination; and water is the chemical union of hydrogen with oxygen. Thus it is obvious, the sources of these organic constituents are inexhaustible. But there is another portion of vegetables which has hitherto been overlooked. It is the incombustible or inorganic structure; that which after combustion remains in the form of ashes, and to which the general and unsatisfactory name of salts is applied. Now, in our system of making manures, we have regard chiefly to the collection of organic matter, and we are surprised and disappointed when the application of this matter fails to produce the required effect. We shall try to show that the cause of this failure is to be attributed to *our neglect in providing for the inorganic constituents of the plants we cultivate.*

It is a rule which cannot now be disputed, that *wherever the analysis of a vegetable product yields, as a constant quality, an inorganic constituent, however small, such inorganic body is absolutely necessary to the healthful condition of the plant;* and it will follow, as a necessary consequence of this rule, that *wherever the soil on which it is attempted to cultivate a plant, is destitute of any one of its inorganic constituents, it will be vain to attempt to grow the plant upon it.* If the material exist in too small a quantity in the soil, the crop will be correspondingly short and sickly.

Regarding this rule as an axiom in enlightened agriculture, we shall draw a few practical results therefrom, in relation to our own pursuits.

The first step necessary towards productive agriculture, and one which falls within the province of our agricultural Societies, is to have vigorous and accurate analysis made, not only of the crops we cultivate, but of the soils on which we raise them, and of the manures which we employ in their cultivation.

Our own Society has the honor of having made one of the first moves in this enterprise, and has furnished an analysis of her principal products. As cotton is our staple, we have devoted this Report exclusively to a consideration of manures suitable for its production. In the analysis of this product, including the wool and the seed, we find the following inorganic constituents:

Carbonate of Potash, with traces of Soda.	Sulphate of Potash.
Phosphate of Lime, with traces of Magnesia.	Chloride of Potassium.
Carbonate of Lime.	Chloride of Magnesium.
Carbonate of Magnesia.	Sulphate of Lime.
Silica	Phosphate of Potash.
Alumina.	Oxide of Iron and Manganese.

Or, by reducing these compounds to simple forms, we find, in the indestructible portion of cotton, potash, lime, magnesia, silica, alumina, sulphur, phosphorus, chlorine, iron, and manganese. This is the general result of the analysis, made for this Society by Professor Shepard. As the same general result was obtained by Dr Ure's analysis, we have every reason to believe that the before named ingredients are all necessary to the perfect development of cotton. Let us now examine the material or soil upon which, and the tools or manures with which, we operate.

The analysis of our soils is yet to be made. The Agricultural Society of St. John's Colleton, enjoys the honor of having taken the lead of her sister Societies in this enterprise. She has furnished an analysis of six specimens of soils taken from a cotton plantation on Edisto Island, of which the following is the general result:

Silica, alumina, peroxide of iron, carbonate of lime, and phosphate of lime.

It would thus appear that the soil of Edisto Island is deficient in four of the nine inorganic constituents of cotton, viz: potash, magnesia, sulphur, and chlorine.

It is to be observed, however, respecting this analysis, that it was made before the publication of Liebig's work on Agricultural Chemistry, and before the important doctrine, laid down in this report, was even partially recognized. It was made too, at a time when the attention of our planters was just beginning to be directed towards the use of lime; and the respectable chemist, by whom the analysis was made, aimed rather to establish the amount of lime existing in the soil, than to demonstrate rigorously all the material, or, as they were then considered, the *immaterial* parts of which it is composed.

Among the soils sent for analysis was a specimen of marsh mud, that agent which has so signally contributed to renovate the soils of the islands on our coast. Its component parts appear to be silica, hornblende, feldspar, alumina, iron, lime, and phosphorus. The hornblende and feldspar of this mud furnish potash, lime, soda, magnesia, manganese, and fluorine; so that with the aid of this manure, the soil is furnished with every constituent of cotton except chlorine and sulphur. It is difficult, however, to conceive how either of these elements can be absent from a mud which is twice daily flowed with sea water. It is rather to be supposed that they are not enumerated, as being too obvious to require a special notice.

Having now ascertained, as far as chemical operations have gone, the general composition of our cotton, and the soils upon which we raise it, let us now inquire what are the ingredients wherewith we propose to amend our soils, so as to increase their productiveness.

The cow-pen and stable have hitherto furnished all our manures. The droppings of our cattle and horses mixed up with the leaves of trees form our composts. Of these, the product of the stable is generally found to be beneficial, while that of the cow-pen is often of so little va-

lue as to discourage the planter in his efforts to obtain it.

One of the most successful planters in this Society has declared, that for many years past, he has ceased to perceive any improvement in his crops from the use of cow-pen manure. The stalks have indeed increased to a large size, but they either produce little fruit, or fail to mature a good crop. It is obvious from this result, that there can be no want of nitrogenized matter in the manure, or it would not promote rank vegetation. The defect must lie in its inorganic constituents, and we may, by comparing the analysis of cotton and of our manures, find wherein the deficiency exists. Let it be remembered, however, that we are hampered in our reasonings by the want of full information which it is the province of the chemist alone to give.

Dr. Ure gives the following as the result of his analysis of cow dung: lime, phosphate of lime, magnesia, iron, alumina, silica, muriate, and sulphate of potash—in other words, all the inorganic constituents of cotton. It is to be remarked, that though all the ingredients are there, yet some exist in almost infinitessimal quantities. Thus, all the chlorine, sulphur, and potash, in 34 lbs. of dried cow dung, amount altogether to about 19 ounces, while the amount of potash alone in a thousand pounds of cotton in the seed, is equivalent to five pounds. Now a good crop of cotton in the limits of this Society, not unfrequently yields a thousand pounds of cotton in the seed, or five pounds of potash, on two acres of land. Let us now suppose a liberal supply of compost bestowed upon two acres. If we say a hundred loads of manure to the two acres, we will far exceed the average amount of manuring. Another liberal allowance would be the supposition of the presence of the equivalent of three bushels of thoroughly dried cow dung in each load of compost, and the measure of our liberality will be filled to overflowing, if we suppose each bushel to weigh fifty pounds. Now, the 15,000 lbs. of cow dung, which is thus applied to the two acres, contain but five pounds of sulphur, chlorine, and potash together, whereas the cotton to be obtained from the two acres, would require five pounds of potash alone. It is obvious, therefore, that if the soil is wanting in these ingredients, the crop of cotton to be obtained by this manuring must fall far short of an average good one, and this becomes perceptibly so, when it is recollected that the whole amount of manure is not consumed in a season, but that its effects are continued for several years.*

It is but just to observe that the urine of the cow, yields by analysis a larger proportional quantity of these necessary ingredients in which the dung is deficient. But this advantage is hardly compensated when we reflect that in a thousand parts of this excrement all the saline ingredients together do not constitute a fiftieth portion.

Chemistry has revealed the composition of the excrements of the cow, a manure which we find decidedly inferior in value to that of the horse. We have not, however, the same accurate analysis of these last to enable us to compare them rigorously. We must use the light we have so far as it goes, and trust to logical deductions for some of the conclusions to which we shall arrive.

And in the first place, chemists differ very materially in the partial analysis which they have made of horse dung. Macaire and Marcet found 27 per cent of inorganic matter or salts, in that analyzed by them. Liebig admits that he has never found over 10 per cent, and Dr. Jackson, of Boston, somewhat under 8 per cent. These discrepancies stagger our faith in the partial results which have been produced. Suppose, however, the lowest to be the most accurate, and we have nearly four times the amount of inorganic matter in the excrements of a horse as in those of a cow. It is to be remarked, also, that the phosphate of magnesia exists in a notable quantity in the dung of a horse, and is also a conspicuous constituent of cotton. The partial report of Dr. Jackson, however, gives no potash nor sulphur whatever. This consideration alone induces us to consider the analysis incomplete, and compels us in the absence of a rigorous analysis, to resort to the indications afforded by a logical investigation.

The cattle whose excrements have been submitted to the test of analysis, are better treated in every respect than those from which we derive our manure. It is a common sense principle, and a rule in practical agriculture is based upon it in Europe, that the excrement of an animal shall bear a fair proportion to the food he eats. Thus in the neighborhood of Hildeshrine, in Germany, the farmers pay a higher price for the excrements of Protestants than for those of Catholics, as those of the latter are impoverished by the numerous fasts enjoined by the Church of Rome. The same must be true likewise of the lower animals. In Europe, where cattle constitute an important item in a farmer's wealth, they are fed with the most nutritious food which they are capable of digesting, and their excrements must partake of the nature of their food. The clover and turneps which the happy cattle of that country consume, are rich in the most valuable inorganic constituents, and hold in large quantities potash, magnesia, sulphur, and phosphorus, and yet, with all this advantage in point of food, their excrements are inferior in value to those of the horse. Far greater then must be the difference here, where the cow is left to her own ingenuity to draw her nourishment from the soil. The grasses abounding in phosphates are not found with us, and it is more than probable that the small quantity of earthy phosphates they do contain, are all required to aid in the formation and support of the bones of the animal, leaving a very minute portion to pass out in the excretions.

The horse on the contrary is as well fed here as in any part of Europe, perhaps (for we have not yet learned the economy of farming) he is better fed. We have therefore a right to expect to find in his excretions the constituents of maize, viz: potash, lime, phosphorus, magnesia, and sulphur, and the quantity of sulphur will be sensibly increased when he is fed on peas. Moreover, his urine yields nearly five per cent. of saline ingredients, while that of a cow falls short of two.

We can thus, by investigating the constitution of the food which the two animals eat, dispense in a great measure with any particular analysis of their excrements, and safely come to the following conclusion: That the inorganic constituents of the excrements of a horse, are more than double in quantity to those of the cow, and that while those of the latter consist chiefly of silicates, those of the former abound in the phosphates of lime and magnesia, two of the most important constituents of cotton.

We would suggest therefore the propriety of improving the value of our cow-pen composts, by the admixture of certain matters of known utility, and either cheap, if purchased with money, or easily accessible to every cotton planter.

And in the first place, we would recommend the addition of a bushel of gypsum for every acre which it is intended to cover with the compost.

The advantage of this mixture is a double one. In the first place, we add to the manure both lime and sulphuric acid, substances which perform important functions, not only in the growth of cotton, but of every crop we cultivate; and, in the second place, we prevent the evaporation of the ammoniacal gases which have always a tendency to escape during the progress of decomposition.

A strong prejudice prevails in many parts of South Carolina against the use of gypsum, and this prejudice is strengthened by the consideration that it was imported largely for the sake of its supposed fertilizing properties, and failed. But it should be remembered that, at that time, the use of any manure was a blind practice, equivalent to quackery; that from the use of gypsum, unaided by other agents, all virtues were expected; that it was used as a panacea for all agricultural evils, and that disappointment was the natural consequence of such unreasonable practices and hopes. And yet, with all the odium attached to its memory, we have heard of some singularly favorable results attending its use. Among others, we have heard that the late Thomas Palmer, Esq., from his plantation in St. Stephens, the average production of which was 60 lbs. of cotton per acre, obtained one year, with the aid of gypsum, an average of 120 lbs. If subsequent experiments resulted in failures, this may be accounted for in a variety of ways; the gypsum may (as lime will do) have exhausted the soil; this is no mystery in countries where lime is used; the seasons may have been unpropitious. And it may be true, that in the absence of any marked beneficial result, our planters may have been discouraged, and seized gladly any pretext for saving their money and avoiding a labor to which they were unaccustomed. Of all men in the world, agriculturists are the most unwilling to follow improvements in their profession, and the readiest to discover the inability of those suggested. Our planters long since knew that lime was used in their very neighborhood with favorable results, but it required the energy and fire of a Ruffin to make the adoption of its use general.

In addition to the gypsum, we would recommend that all the spare cotton seed should be cast upon the compost heap. It is needless to dwell, before this Society, upon the inestimable value of this manure. We would only suggest that the cow-pen would be materially improved, while the cotton seed would be permitted to be spread profitably, though in small quantities, over a much greater surface than they could be if applied in the usual way.

Lastly, we would perfect the compost by the addition of ashes. There is no manure, cotton seed perhaps excepted, which, applied singly to land, produces such striking results. The ashes of the oak, though most accessible to us, contain all the inorganic constituents of cotton, and are particularly rich in lime, potash, sulphuric acid, chlorine, and phosphoric acid, while they contain so much of all its other constituents as to preclude the idea of deficiency in any.

It may be objected to the addition of ashes to the compost heap, that the mixture will hasten the evolution of ammonia, and thus rob the manure of its nitrogen. If, however, gypsum be applied previously, or in combination with the ashes, this objection will in a great measure be removed, since the ammonia has an affinity with the sulphuric acid of the gypsum, with which it forms a solid body, the sulphate of ammonia. But even were this not the case, observation has taught that it is almost impossible to expel all the nitrogen; that which remains, will unite with the potash; in the great laboratory of nature, fresh supplies will be elicited from the atmosphere, and the result will be the nitrate of potash, or common saltpetre of commerce, an agricultural agent at least as valuable as any preparation of ammonia can be.

We close our report with the relation of a few facts, coming under our observation, corroboratory of the views we have offered.

On the 22d day of August last, the Committee on Manures visited Fair Spring, the plantation of Mr. Robert Mazyck, to witness the result of his experiments with green sand. This marl, of which this is the only locality hitherto discovered in the State, is found in a ravine, on the Eastern side of Begin Swamp. It is of a lively green color, so soft as to be easily turned

* Since the above was written, we have seen Dr Davis's statement, that the weight of cow dung, as evacuated, is just 87 pounds. Now, if 83 per cent. of this be water, the allowance of 50 lbs, as the weight of the dry dung, is indeed an excess of liberality. The true weight of the dry dung is just 22 lbs and the quantity necessary to equal 15,000 lbs., would be 652 bushels. Compare this with the statement in the text, and we will see how small a portion of these salts is conveyed to the soil through the medium of cow dung.

out with the spade, is full of fossils, indicating the presence of lime in its various modes of existence, and is said to be rich in potash. It is to be regretted that Mr. Mazick did not accurately observe the quantity applied to his land; and it is rather too early in the season for us to be furnished with the results of his experiment. At that late period of the summer, however, a practical eye can judge with tolerable accuracy what the result will be. It required but a glance to convince us, that the cotton manured with green sand was worth three-fold the best portion of his crop not so manured. We can give no better idea of its appearance than by comparing it to a pyramid of luxuriant vegetation, rising so abruptly from out of the rest of the cotton, as to be at a glance obvious to the most careless spectator; and the quantity and maturity of the fruit corresponded with the luxuriance of the plant.

Less striking in appearance on that same day was a field at Somerton, manured with twenty loads of cow-pen compost, and twenty bushels of ashes per acre. But even this small quantity of ashes caused such a difference in the growth and maturity of the cotton as to be easily distinguished from that which had none. A part of the result of the experiment at Somerton is known, and corroborates our opinion that ashes should be mingled with the compost. At the second picking of cotton, before the middle of September, four hundred pounds per acre of cotton in the seed were harvested from that portion which had ashes. It is but just, however, to observe, that in this case the ashes formed no portion of the compost; they were spread upon the list; the compost placed under.

One of the Committee has recently seen a crop of cotton in St. Andrew's Parish, which he thinks would be estimated at too low a rate at a thousand pounds of seed cotton per acre. This result was effected by using the fine particles of compost at the bottom of the manure heap. In this case the active particles of the compost heap were concentrated at the bottom; for they always have a tendency to descend, being carried down, partly in a state of solution, partly by the mechanical action of rains. The result of these three instances are with us conclusive, *that the action of manures is directly in proportion to the amount and quality of their inorganic constituents, and that to the collection of these, the planter should mainly direct his attention.*

Offering the accompanying Resolutions, as necessary to carry into operation the principles of this Report, we shall no longer trespass upon the patience of the Society.

In behalf of the Committee.

FRED. A. PORCHER.

RESOLUTIONS OF THE COMMITTEE ON MANURES.

1. That it be recommended to the Society to appropriate adequate funds to the accomplishment of a thorough analysis of all the products of our soils, of our soils themselves, and of our manures.

2 That we earnestly recommend to our sister Societies throughout the State, to contribute to a similar analysis of their soils and productions.

3. That the Representatives to the Legislature from these parishes, be respectfully requested to urge upon their respective houses the necessity and expediency of perfecting the Agricultural Survey of the State, so happily begun.

NOTE.—A few observations are yet necessary to perfect the report, which has grown under our hands, to an unexpected length. It will be observed, that we have taken no notice whatever of the amount of inorganic matter existing in the litter with which our compost is made. As this is an equal quantity in both sorts of compost, it cannot, as a general rule, materially affect the relative value of either. With respect to what has been said in the earlier part of the report respecting the theories of the chemists, we cheerfully acknowledge our unfitness to sit in judgment upon their merits. We do know, however, when they give us satisfactory replies to our queries, and we are painfully conscious when they fail to answer us: and the worst of it too is, that they undertake to speak a language intelligible to every farmer. Now in our humble judgment, when a farmer consults a book purely scientific, for information relative to his profession, he expects to find the language of science, and is generally prepared to meet it. Now, what can be more unsatisfactory than the following. We inquired into the composition of cow dung. Dr. Dana says, "I give you the result of my analysis of cow dung *in such terms as the farmer may comprehend;* water 83 60; hay 14; biliary matter (bile resin, fat and green resin of hay) 1.275; geine combined with potash, (vegetable extract,) 0.95; albumen, 0.175" If the farmer may comprehend this, may he not equally comprehend the results of a destructive analysis? Is it not likely that the farmer would better appreciate the value of silica, alumina, lime, magnesia, &c., than of this mysterious geine which is thus forced upon his attention? Particularly when he is told that all these are constituent portions of the crop he cultivates. Let the chemist use the language of his profession, and give the result of his labors, and the farmer will thank him.

From the Louisville Journal.

Close Planting of Corn—An Experiment.

GENTLEMEN:—I beg leave to offer to your consideration the result of an experiment made during the present year, to ascertain the advantages of planting corn more closely than has generally been practised; and the number of stalks which should be left in each hill at the different distances at which it is planted. The experiment was made on ground which had been cleared in 1810. In its natural state it was as rich as the best Kentucky lands, and its fertility had been preserved by a due proportion of grass crops, but it had had no manure. In the spring of the year 1841 the field was sowed with red clover, among growing wheat. In 1842 and 1843 the clover was pastured, and late in the fall the ground was well turned over, by a well constructed plow. Early in April of the present year, the ground was again plowed, harrowed, and laid off and planted on the 12th of that month. On one side of the field, intended for hemp, I caused four acres to be laid off, in an oblong square, as follows: First, the long way exactly three and a half feet; and then at right angles, four feet; one acre three and a half feet; one acre three feet; and one acre two and a half feet. In due time I thinned the three first acres to three stalks in a hill, and the fourth to two stalks in a hill. Supposing the hills each to have the number intended, the number of stalks on each acre would have been as follows:

1 acre 3½ by 4	feet	9.335 stalks
2 acres 3½ by 3½	feet	10,668 "
3 acres 2½ by 3	feet	12,447 "
4 acres 3½ by 1½	feet	9,956 "

The season up to the 2d of July was tolerably favorable, though there was too much rain for a first-rate crop of corn. For two weeks succeeding no rain fell. During this period the atmosphere was dry and windy. As the corn was generally getting into silk when this drought commenced, and as this is the period when corn requires much rain to make it *ear well*, it suffered very much. Although light rains again fell from the middle of July to the last of that month they came too late to be materially beneficial to early planted corn. The consequence was that scarcely a stalk produced more than one ear, and even that one of diminished size. I am fully persuaded that the dry weather, in the first half of July, diminished the crop at least fifty per cent. The crop was also somewhat diminished by great numbers of crows opening and picking off the grains at the small end of the ear, when in the milk state. The corn was gathered, and each acre separately measured, about the first of November, when perfectly dry, and the quantity produced was as follows: The first acre 68 bushels, second acre 69 bushels, third acre 69 bushels, and fourth acre 77½ bushels. The ground throughout lays equally well, and was of the same quality, but the first acre was rather the most injured by the crows.

It will be seen that the acre, planted three and a half by four feet, produced nearly as well (perhaps quite, making a due allowance for the injury received) as the two next acres. That the acre having 12,447 stalks produced only the same number of bushels as that having 10,668. And that the acre having two stalks in the hill, and 9,956 in the whole, produced eight and a half bushels more than either of the others.

From this experiment it would seem that, in ground of the *best quality*, where *three stalks* are intended to be left in a hill, the distance each way should not be less than three and a half feet: and that, where it is intended to plant more closely, not more than *two stalks* should be left in a hill. The acre planted three and a half by two and a half feet produced decidedly the best, but it was too close one way to be plowed conveniently. Thus planted there were eight and three-quarters square feet to each hill. If planted three feet each way there would be nine square feet to each hill. This, I am of opinion, would be the better way to plant, where it is intended to leave two stalks in a hill, as the distance each way would be more convenient for plowing, and the number of stalks per acre would be but slightly diminished.

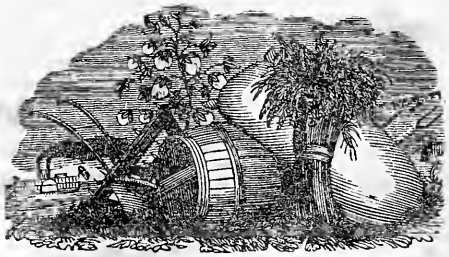
As our corn crops are affected by so many contingencies, a single experiment is not very conclusive in favor of any particular theory, I intend, if I am spared, to repeat my experiment next year on the same ground, except that I will lay off the ground the long way, three feet, and in the other direction four, three and a half, and three feet, thinning the two first to three stalks, and the third to two stalks in a hill.

On the day after planting the above experimental crop, I planted some twelve or fifteen acres of corn on ground which had been cleared and cultivated some twenty or twenty-five years before I came into possession of the plantation on which I now reside—1812. This land had been considerably reduced by a long succession of corn crops, but as it lay well I found no difficulty in renovating it by grassing and manuring. For the three or four years preceding the present it was cultivated in hemp. Early in April it was plowed and harrowed, which left it in a finely pulverised state. It was laid off by a small plow exactly three and a half feet each way, planted on the 13th of April, and in due time thinned out to three stalks in the hill. It was cultivated by plowing both ways with the common shovel plow and once hoed, so as to leave the hills perfectly clean. This corn was affected by the drought in July in the same manner as related in relation to the four acres described above.

I caused one acre to be pulled and measured when perfectly dry, through the central part of the field, where it had not been injured by the crows or squirrels, and the yield was seventy-seven bushels. In both cases I planted the same kind of corn, a medium between the white flint and gourd seed. This corn is not so productive as the larger kinds, but better for bread.

I have mentioned the product of the last mentioned acre, not because of its extraordinary character—for it falls greatly short of the great crops of Bryant and Young, of Jessamine county – but to show that land cleared nearly sixty years, and which had been reduced by twenty or twenty-five successive crops of corn, can be easily renovated so as to produce seventy-seven bushels per acre, in quite an unfavorable season. I will only add, that although I did not measure the balance of the field, I am satisfied, from the number of wagon loads, that the whole would average fully seventy-seven bushels per acre. Yours, truly,

Prospect Hill, Dec. 7, 1844. A. BEATTY.



The Southern Cultivator.

AUGUSTA, GA.

SATURDAY, MARCH 1, 1845.

To our Exchanges.—Those Agricultural Journals with which we exchange will confer a favor by addressing to us at Athens in future.

Manures.—We don't think those readers who like to look into the plain "why and because" of things can have a much richer treat, than is furnished them in the admirable report on Manures, by Dr. Porcher, of South Carolina.

Colman's European Agriculture.—We have read with a great deal of pleasure, and profit too, the second number of Mr. Colman's "European Agriculture and Rural Economy," and we wish it was in the hands of every man in the Southern States: for it furnishes very many happy illustrations of what care and skill will do in increasing the productions of the soil.

Far as we are behind the age in respect to our system of agriculture, the reader of Mr. Colman's work will find in it very many reasons to congratulate himself on account of the portion of the earth in which his lot has been cast; but especially on account of the institutions under which it is his good fortune to live. Not indeed that we should be satisfied with our situation as it now is, and make no effort to better it, but that, with all its defects, it is far better, comparatively speaking, than can possibly be enjoyed by the corresponding classes in Europe.

We were about preparing an abstract of this number of Mr. Colman's work, when a synopsis of it came to hand in the Albany Cultivator, which will be found in another column.

Pork and other Matters.—Our correspondent, "J.," whose article we commend to the reader's attention, states the fact that the people of Putnam County, last year, paid five thousand dollars for the article of pork; and he estimates that the value of three hundred and fifty bags of cotton was thereby consumed. We wish "J." had pushed his inquiries a little farther, and furnished our readers with an estimate of what was paid last year in Putnam County for carriages, horses and mules, cotton bagging, tubs, pails, buckets, brooms, axe-handles and axes, hoes, fine boots and shoes, negro shoes, saddles and bridles, all of foreign manufacture. Cannot he do this yet, and thus furnish an array of facts and figures, which, convincing every one of the folly of his past conduct, will compel him, for the future, to do otherwise than make cotton alone, and buy every thing that is consumed on his plantation except bread.

Our correspondent also makes the statement that there are thirty-five counties in Georgia, in which, last year, the like sum was spent for meat alone. Will "J." extend the calculation proposed to be made as to Putnam County, through all the thirty-five counties, and let the people see the result? He has the ability to make a decisive impression on the public mind as to these matters, if he can be prevailed upon to exercise it.

We subjoin a statement of the keeper of the toll-gate on French Broad river relating to the same subject; remarking, however, what will occur to almost every one, that but a small portion of the stock consumed by Georgia comes by the French Broad route.

TABLE, showing the number of horses and mules, hogs, black cattle and sheep, that passed over the Paint Mountain, in North Carolina, for the South Carolina and Georgia markets:

	Horses and Mules.	*Hogs.*	*Blk. Cattle.*	*Sheep.*

	21,305	227,004	15,599	14,460

The Cash System.—The National Intelligencer, noticing the new agricultural publication, called the "Ohio Cultivator," speaks thus:

"New advocates of this great national pursuit appear to be rising up in all parts of the country. The last announced is that of the '*Ohio Cultivator*,' at Columbus, by M. B. Bateham, late editor of the Genesee Farmer. From what we hear of his experience, ability, and liberal aims, it is to be wished that his success may be commensurate with his deserts and his most sanguine hopes: though it is not quite clear how his own 'capital and labor' can find adequate return at the rate of $1 per annum for a semi-monthly 'in quarto form, (8 pages,) making a large volume, with a title-page and index!' All, however, that his best friends can ask for him is, that his paper (not his person) may grow with the growth and strengthen with the strength of the flourishing commonwealth he has chosen as the field for his industry and enterprise.

"Mr. B. will be entitled to a first-rate premium if, in the field he has entered, he can teach how to prevent the appearance of a weed which we understand is very troublesome and unprofitable to agricultural works, called the '*delinquent subscriber*,' and which is said to be very apt to make its appearance after the first year's cultivation of new ground."

From something like thirteen years' experience as a political editor, we can speak of that most troublesome and unprofitable weed called by the Intelligencer the "*delinquent subscriber*." It is, in truth, a most abominable pest, even in those concerns devoted to the cultivation of politics; and if it were permitted to spring up at all in those devoted to the cultivation of the soil, they could not exist.

This difficulty can only be avoided by doing as we do, and as nearly every agricultural paper in the Union does: that is, to require payment in advance, in every instance. Adopting this system, and acting on it strictly, enables us to put the subscription down to *One Dollar* per annum. Whereas, if we were to publish the paper on credit, and take the risk of delinquent subscribers, we could hardly afford to publish it at *Three Dollars*. So great is the difference between cash and credit, in the business of publishing papers dependent altogether on subscriptions for support.

To many persons, whose word is good, wherever they are known, for thousands, it may at first view seem hard that they are denied credit for the paltry sum of one dollar, the annual subscription to the Cultivator. But they have only to recollect, that having found it indis ensable to establish the rule of cash payments, as enabling us to put the paper at a very low rate, and thus bring it within the reach of every body, there can be no exceptions to the rule without giving serious offence.

Political Economy.—Be it distinctly known to all whom it may concern, that the Cultivator eschews party politics as it would avoid a pestilence. Nothing shall induce it to depart from this determination. Yet there is a science, having a very close connection with politics—not party politics though—as well as with the business concerns of all men, and more especially with planters, called political economy. It proposes to unfold the laws which govern the production, distribution and consumption of wealth. Discussions connected with this science come properly within the scope and aim of an agricultural paper; and from the pleasure and profit of such discussions we shall certainly not debar either ourselves or our readers, even though, by those who really know nothing of what they are talking about, it may be insinuated that we are meddling with party politics, when our only aim shall be to show in what respect the principles of political economy may be violated, and the interests of the agricultural class sacrificed by either state or national legislation. The number and the importance of the agricultural class, would seem to us to require this of any publication that is faithful to their interest. The last census shows that about eighty out of every hundred of the population of the United States, are interested directly in the soil, and derive their subsistence from its cultivation. They have to bear the chief part of the public burden, when the State wants money: they have to shoulder the musket when the country is to be defended. Their interest is the great interest of the nation, which being sacrificed, the nation must sink.

There is just about the same difference between political economy and party politics as there is between mid-day sunshine, and midnight darkness.

Plows.—At first view, it would seem that it is a very simple business to make a plow;—and indeed it is an easy matter to make such plows as are used in the slovenly agriculture of the South;—but in other parts of the United States, great attention has been bestowed on the improvement of this most important implement. And the consequence has been that now a great deal more work is done by the same force in the same time, and it is done a great deal better than formerly. In old times, in some parts of New England, to plow green sward, required a force of three yoke of oxen, with a horse to lead, with two drivers, one man at the plow handles, another at the beam to keep the plow

in the ground, and often a man to follow with a hoe to turn over the furrows, where the plow did its office imperfectly. With all this force, an acre per day was considered good work. Now, under the very same circumstances, an acre and a half is plowed per day, with a single yoke of oxen, and one man: and the work is done in a manner infinitely superior to the old mode. All this has resulted from the improvements that have been made in the plow. Some of the strongest minds in the country have been directed to the subject. Even so far back as the times of Timothy Pickering, who had been Secretary of State under Washington, this matter was engaging the attention of intelligent men. Mr. Pickering gave the following rule for the construction of the mold-board:

"Having fixed a straight line, by one cut of a saw from the upper corner of the mold-board behind, to its point forward, cut away the wood above and below that line in such a manner that when finished if you carry a straight rule from the fore to the hind part, keeping it all the way at right angles with the straight line, it shall touch the face of the mold board, in its whole breadth, in straight lines, through its entire winding, so that its upper corner behind shall overhang the lower sufficien ly to effect a complete turning of the furrow slice."

The Albany Cultivator, from which we get the information stated herein about ancient and modern plowing in New England, says that this rule of Mr. Pickering is still adhered to in all the modern improvements of the plow. How many plows are there in Georgia constructed according to this rule; or, indeed, according to any fixed rule?

Grape Vines.—The usual way of propagating grape vines among planters, is by cuttings, or layers. With professional gardeners, there are other modes, involving the refinements of science, and requiring an amount of care and attention which none but prof ssional gardeners can bestow on the business. In the common mode, with all the attention that can usually be given to the process, success is very far from being certain. Hence the small extent to which even good grapes are multiplied in the Southern States. When a single vine shall have been once established, there is a mode by which it can be multiplied to any moderate extent, by layers, without much trouble. We are indebted to Mr. Affleck, of Ingleside, Miss., for an account of it. In a letter to the editor, of 28th January, he says:—

"Let me give you the benefit of a hint I got in *propagating* the grape, from the last gardener I had. After selecting your vines (shoots) for layering, open trenches, say two inches deep, (after properly preparing the ground, of course,) in convenient positions for layering, and in these trenches peg down the vines, before the buds begin to swell, or about that time, without cutting into or twisting the vines, and leave them so, *without any covering of earth*, until they make shoots a foot long. Then cover up carefully by hand, and lay a little litter over to keep moist. *Each eye* will then make you such plants as I send you. I had some even much stronger, but they are planted out. By the old plan of covering up at once, I did not get any such plants, nor near so many."

The road ambition travels is too narrow for friendship; too crooked for love; too rugged for honesty; and too dark for science.

Lard Lamps.—Bacon's Lard Lamps, an advertisement of which will be found on the last page of the Cultivator, are exactly as they are described to be. We have tried them, and therefore speak from personal observation. We have weighed the lard and measured the time, and find the rate of consumption to be one ounce for two hours; that is, supposing the lard to cost 8 cents per lb., the cost is one-fourth of a cent per hour. That is a degree of economy altogether suitable to the times. The light is a very pleasant one, without either smoke or disagreeable smell so often occasioned by burning oil. In addition to all this, the lamp is a very neat article, and very cheap; and is withal so simple in construction, as to occasion no difficulty in its management.

Improvement in Virginia.—In our January number, we said that the emigrants from New York were rapidly improving the poorest lands in some of the poorest counties in Virginia. There has been, very naturally, a good deal of curiosity excited to know how this result is being brought about, the opinion being, that from similarity of soil and climate in Virginia and Georgia, the process that succeeds there will answer here also. Happily for all whose attention is turned to this subject, we have, in the Southern Planter, a brief outline of the practice of the New York emigrants in Virginia. Mr. Botts, the editor, says:—

"They came poor to poor land, and they are getting rich and getting their lands rich too, with no other means than their starving predecessors enjoyed. He says that they are not more intelligent generally, probably not as much so, as the natives around them. Nor are they more scientific cultivators of the soil; but the great secret is, they save every thing and they make every thing work; they buy as little as possible: the money they do spend, is either for the absolute necessaries of life that can't be made at home, or for manure, good implements, and other things calculated to increase their products. In this latter class of articles, he says, they are the most liberal purchasers for their means he ever saw. But they save and husband every thing upon the farm that will make manure, as if it were gold. A close log pen is made, the bottom of which is puddled, and this is the universal depository for the sweepings of the house, the emptyings of the wash tubs, the offal of their victuals, and every thing else that a Virginian throws away. There are no drones in the hive; men and boys, old women, young girls and little children, all work incessantly. After a child is six years old, he is a help rather than an incumbrance, in a pecuniary point of view. Thus they grow rich, where their neighbors would grow poorer every day; and such are the happy effects of well regulated labor, that their pecuniary prosperity is only equalled by the comfort, cleanliness, and happiness of their homes."

Hotchkiss' Water Wheels.—We would call the attention of mill owners to the advertisement of Mr. Hotchkiss' Premium Vertical Water Wheels, to be found on our last page. The certificates annexed, from practical men who have witnessed their operation, sufficiently attest the value of the invention.

Relief of Asthma.—Get some blotting paper and soak it well in a strong solution of saltpetre. Take it out and dry it. On going to bed light it, and lay it on a plate in your bed-room. This may enable persons badly afflicted to sleep well.

ORIGINAL COMMUNICATIONS.

For the Southern Cultivator.

Flowers.—Charcoal as a Manure.

Mr. Editor:—I am no farmer, an I therefore, perhaps, am not entitled to a place in your columns. But I shall address myself to your fair readers, and with this dedication, I know your gallantry will not allow you to expel me from them.

I design to speak of flowers, and their cultivation in part. Last spring, I noticed several articles on the use of charcoal as a manure. I was induced to try some experiments with it, on different flowers, and the effects were favorable beyond conception. I give you a statement of my experiments, for the benefit of the ladies, who, "the fairest of all flowers," delight in the cultivation of a splendid flower.

My first experiment was on the Chinese *hybiscus*. It was small, had been much affected by the frost, had turned yellow, and had all the appearances of a rapid decay. I mixed equal parts of charcoal and earth, and applied to the roots. In two weeks, it began to change color and to grow. In two months, it had grown more than two fee . I then added well rotted cow manure, and on to Christmas it continued to grow and bloom most splendidly.

The next experiment, was one upon orange and lemon trees. The surface soil was removed to the roots, and charcoal also applied. The effect was equally as great. So, likewise, was the effect produced upon the India-rubber tree

Another experiment was upon the geranium. It gave health and vigor to the plant, and produced an abundant crop of blooms, enlarged in size, and increased in richness of color. I discovered, however, that the plants were more easily hurt, by the warm weather, than formerly. So, taking the hint, I removed the charcoal, and applied earth in its place. In one instance, I *covered* the charcoal with earth. The effect which followed in both cases, was all that I desired. The quantity of charcoal applied, was equal in parts with earth.

Another experiment, was upon the *Cactus*. I applied about one-fourth charcoal, mixed with surface soil. The effect was to produce rapid growth, strong and large flowers, as well as to protect, to a great extent, the plants from decay or rot.

A *Cactus speciocissimus* had been potted two years, had rooted well, but never grown a particle. I planted it in charcoal, half earth. In ten days the bud began to swell; and in thirty, the shoot was more than two inches long. It grew finely the whole year. I applied one-fourth charcoal to the *Cactus truncatus* with great effect, enlarging the wood very much, hastening the bloom ten days before the time, in the previous year, enlarging the number and increasing their brilliancy.

The same application was made to the *C. septangularis*, which increased its growth very much; but the age of the plant prevented its blooming, and therefore I cannot speak of the effect which it would have produced.

The C. truncatus and C. speciosus both were manured with charcoal, and increased growth, number, size and quality of flowers, was the result.

For the Cactus, charcoal is decidedly the best stimulant I have ever tried. One thing, however, should always be borne in mind in its application: it is very porous, and consequently admits the air freely to the roots of the plant, drying, and consequently destroying them. Whether it be applied in large or small quantities, it should be covered with an inch or two of earth, or else daily waterings given.

Upon the Camelia-Japonica, I likewise made experiments. Not more than one-fifth charcoal was mixed with the earth, which was poured around the ball of earth and roots, when transferred to a larger pot. No perceptible effect was produced upon the plant during the summer. The roots, I found upon upsetting in

the fall, had grown very much, and this winter I begin to realize the benefit in the bloom. The flowers are double in number, and the size very much increased, far beyond anything I have ever seen before. I have now a *C. fimbriata* in bloom, three inches and a half in diameter, and the stalk not eighteen inches high. An Imbricata is likewise blooming, very much enlarged.

I experimented upon the *Euphorbia Poinsettia*, which had been killed to the earth by frost. The result was a growth of thirteen feet in one year, with leaf and flower much improved in size and beauty.

I believe the best mixture which can be made with charcoal, is that of well rotted cow manure. This will answer for the greater portion of plants; but the florist will discover very soon that it will not answer to add a large portion of the coal. The plants will thereby suffer a great deal, and render frequent and heavy waterings necessary.

In every instance, I have found that charcoal added richness to the foliage; and in the case of the Hybiscus, the color of the flower was changed to a very deep, from a light red. I placed some *hyacinths* in jars in this mixture, which resulted in nothing favorable. I am now trying the effect of *guano*, in solution, upon my flowers; and from twenty day's experience, I believe it will answer very well in many instances.

I have found much difficulty in managing the finer and more delicate varieties of the Geranium to obtain fine foliage and rich, large blooms. At last, however, I have succeeded to my satisfaction. Take unrotted cow manure, beat very fine; remove the earth down to the small roots; apply two inches of this manure; press it down well and water frequently. This plan I know will produce a fine plant, and still finer blooms. If any of your fair readers can furnish me with a better mode, I shall be thankful. The plan of cultivating the Geranium at the North, and in green-houses, by skilful gardeners, cannot be practised upon in our parlors—the green-houses of Southern ladies. I lost sixty plants of the rare and delicate kinds in one year, by attempting to ape the course of others in this matter.

But, Mr. Editor, I must stop. I have run out my paper without observing it. Should you think the foregoing worthy a perusal, place it in the ladies' corner. M.

For the Southern Cultivator.

Analysis of Soils and Crops.

Mr. Editor:—For some twenty long years I have been vexing and treating mother earth most cruelly to make the "pot boil." The want of science, the want of attention and attendance, a preference for political rather than agricultural reading; and last, though not least, that mistaken idea, too commonly entertained by native Georgians, that labor is not reputable—all combined, have rendered me unworthy the name of Farmer. But, if I have done wrong for a long time, it is no reason that I know of why I should always do so. I now want to understand the *why* and the *wherefore* of my business. If I can find out where it is, and what it is, I wish to begin at the beginning, to learn, if I can, the farmer's alphabet. If you would publish in the Southern Cultivator, the analysis of corn, of wheat, of rye, of oats, and of cotton, also the analysis of a perfect soil, it seems to me something would be known about the means necessary to improve land, and to make a good crop. Corn is indispensable to the welfare of my family. If I knew how to supply the deficiencies of my soil, and to feed my corn with the food best adapted to its use, with the blessings of heaven, I think a large crop would be as certain as two and three make five. This principle will apply to all crops. A plenty of pork, beef, mutton, milk and butter, are very desirable. Nor is plenty of geese, turkies, ducks, chickens and eggs, at all objectional. Some fine ladies and gentlemen, the one with a novel in her hand, the other with a cigar in his mouth, may laugh at these things, yet a backwoodsman knows they are useful and likes to have them. I want to know the breed of hogs that will give the most good meat for the food consumed: how to feed and what to feed with, to produce flesh, and to make fat. (But spare, oh spare the Berkshires; they have brought me to buying pork.) I want to know what kind of cattle will suit best for the dairy, the yoke and the shambles, and how to feed them. (Again I say, spare the Durhams. Mine have died.) I want to know also the kind of sheep best adapted to the soil and climate of Georgia: how to feed and what to feed with, to produce flesh and fat and wool. Any information on the subject of poultry will be thankfully received.

My ignorance about my own business, and the only business too by which I live, is so great, and consequently my wants are so many, I am fearful you will become tired before they are supplied. But if I could get the information asked, I think I should begin to find out something of the whereabouts of it.

Of you, the Georgia Journal thundered tremendously to make Governors. 'Tis hoped the Southern Cultivator will now lighten with effulgence to make Farmers.

Respectfully, your obd't. serv't.,
Clodhopper, of Houston County.
Houston Co., Feb. 8, 1845.

For the Southern Cultivator.

Advice to Planters.

Mr. Editor:—The universal question which is asked is, what can we do to better our condition? It strikes me that there is a very ready answer to it, and one which is as efficient, if practised, as prompt: *Live at home and diversify your pursuits.* In these hard, pinching times—money scarce and cotton almost worthless—the farmers of Putnam county paid to Tennessee and Kentucky, by drovers, *five thousand dollars for pork* this season! Can you wonder that times are hard with farmers, when they buy what they eat, instead of raising it? It required the proceeds of three hundred and fifty bales of cotton to purchase this meat. There are, in Georgia, thirty-five counties, which, on an average, have sent a like amount of money from the State, and for the same purpose. Suppose, instead of buying this meat, the farmers had diminished their cotton crop so much, and raised their own pork, they would not only have had *better* meat, but the cotton crop would have been diminished in these counties more than three thousand bags. The same policy pursued throughout the cotton growing States would tend very much to reduce the production within the demand, and a better price would follow for that made. But, to raise our pork, we must be economists in our provisions; and how we can increase the *amount* without a corresponding increase of labor, is the great mystery. Manure your corn land well, and a less quantity will yield a greater amount of grain. The time saved in cultivating the less quantity of land will afford opportunity to collect and make and apply the manure.

But there are substitutes which may be used instead of corn. The Jerusalem artichoke yields abundantly. The culture is simple, and hogs are exceedingly fond of them.

Last year, for the first time, they were introduced into middle Georgia, and proved themselves great multipliers. Mr. Joseph Wilks, of this county, dug four hills a few days since, and gathered *five* pecks of roots: one hill yielding just half a bushel.

Now, Mr. Editor, if you will give a history of this root, its nutritive qualities, and its value for stock, you will confer a very great favor on your readers. For, if worthy of cultivation, many will go largely into it this year and thereby many a pound of good Georgia pork, may supply the place of the range-fatted hogs of Tennessee. J.

Putnam County, Ga.

Pride costs us more than hunger, thirst, and cold.

Agricultural Meeting in Milledgeville.

The call for an Agricultural Convention at Milledgeville, on the 27th. January, was responded to by so few persons, that those present declined doing anything more than the adoption of the following Resolutions, to which we invite the attention of the public.

Milledgeville, 27th Jan., 1845.

A few citizens having convened in Mrs. Huson's long room, in pursuance of a call in the public papers, among whom were Messrs. Richard Rowell, Leroy Singleton, James Dixon, Benj. Lester, Mark Huson, Allen Little, W. Y. Hansell, John S. Thomas, Wm. Turner and others; Major Rowell was called to the Chair, and Wm. Turner acted as Secretary.

After some remarks from several gentlemen, Wm. Turner offered several resolutions: which, being considered and amended, were adopted, as follows:

1. *Resolved*, That an Agricultural Convention be held in Milledgeville on the fifth Monday in March next, to consist of delegates to be appointed on the part of the different counties, and such other persons as may be invited to partake in the proceedings.

2. *Resolved*, That the different counties be requested to appoint delegates accordingly.

3. *Resolved*, That a committee of three, including the Chairman, be appointed to draft and publish an address, in order to promote the purpose of this meeting.

4. *Resolved*, That among other proceedings, the committee recommend the formation of agricultural associations, in the different counties, and agricultural meetings or associations in the different judicial circuits.

The committee appointed under the third resolution, consists of Messrs. Rowell, Singleton and Turner.

On motion of Mr. Lester,

Resolved, That the proceedings of this meeting be published in the Milledgeville papers, and such other papers as may take an interest in them—particularly the Southern Cultivator.

Richard Rowell, Chairman.
Wm. Turner, Acting Sec'ry.

TO THE PEOPLE OF GEORGIA.

Fellow-Citizens:—On the 27th ult., a small number of persons assembled in Milledgeville, for the purpose of consulting on the great interests of agriculture. After due deliberation, several resolutions were adopted by the meeting.*

The undersigned are the committee appointed under the third resolution. They regret that they have not been delegated by a larger assemblage of citizens, and especially that they are unable to present the great interests of agriculture in so commanding a light as they desire. They trust, however, that the day of small things, will not be despised, and they proceed to the discharge of the duty assigned them

As inducements to our fellow-citizens to concur in the movement which has been attempted, they advert to the depressed state of agriculture, the imperfect state of household economy, the praiseworthy example of several agricultural associations, especially that of Hancock, which has exerted so beneficial an influence, and the stirring appeals recently made to our interests and our patriotism, in several of our public journals.

Let not the failure to get up a Convention on the 27th ult., arrest our efforts; more determined endeavors may yet succeed. It is only necessary to bring together the increasing friends of our enterprise. And we cannot but hope, with the intelligent editor of the Southern Cultivator, "that in a very few years, almost every county in the State will have its Club, and that all of them will be but branches of a great State Agricultural Society."

Let, then, our fellow citizens forthwith, get

* We omit the resolutions here, as they will be found in the proceedings of the meeting above.—Ed. Cult.

up county meetings and associations; which, like the Hancock Club, may do much good, if they go no further. But let them extend the good by meetings and associations in the judicial circuits, if they desire them; though the Committee are a little apprehensive that these latter may interfere with the purpose of *a State Society or Convention;* which they desire by all means to see got up.

It is scarcely necessary to say, that agricultural associations will be merely consultative and advisory: there will of course be nothing compulsory in any thing they may do. This is said in view of the purpose entertained in the attempt to get up a Convention on the 27th. It was thought desirable by some, in view of the low prices of cotton, to induce our farmers to reduce the quantity, in order to improve the price. That this reduction would have this tendency there can be no doubt. The reciprocal influence of demand, price and supply is obvious. An increased demand is followed by increased prices; increased prices by increased supply; increased supply by diminished prices; diminished prices by diminished supplies; diminished supplies by increased demand, increased prices, and so on. A reduction in the quantity of cotton, then, would be followed by an augmentation of price; more especially as this reduction would enable farmers to prepare their cotton more carefully for market.

But, even if the price of cotton should not be improved, the withdrawal of a part of our labor from the production, would enable us to employ it more profitably in other operations. It is disreputable as well as ruinous to purchase from others so many articles which might be produced by ourselves. It is absurd to raise cotton at present or probable prices, to purchase horses, mules, cattle, hogs, sheep, ordinary clothing, or other articles, which might, and ought to be produced at home. The countless thousands which are expended in this way ought to be retained among us. And we are gratified to find that such is the present tendency. To continue, and increase this tendency is the desire of the Committee.

It does not come within the present purpose of the Committee, nor are they prepared, to give the statistics which would sustain their views. They confidently rely upon the recollections of their fellow-citizens, aided by the developements which are constantly manifesting themselves, to make the proper impressions.

Among the objects to which a part of our efforts might be profitably directed are wool, silk, indigo, tobacco, butter, perhaps apples in some situations, &c.

Even if these would not be very profitable objects, the labor withdrawn from overstrained efforts to produce cotton, would enable us to build or repair fences, build or repair houses, collect manure, ditch our hill-sides, drain our low grounds, and constantly add to the value of our lands and negroes, the intellectual and moral improvement of ourselves and families, and the prosperity and comfort of the community.

Come up, then, fellow-citizens, to the rescue. Though miserably lacerated, good old Georgia contains within her bosom all the elements of a great republic, and a happy people. All the inventions of interest and patriotism call on you to say that her sun shall not decline in the gloom which threatens her!

Your fellow-citizens,

RICHARD ROWELL.
LEROY SINGLETON.
Feb. 1, 1845. WM. TURNER.

Farmers' Meeting in Harris County.

Pursuant to former notice, a respectable portion of the farming community met this day in the Court House in the town of Hamilton, to deliberate upon their interest as a cotton-growing people, and to give expression to their views as to what might best promote that interest. The meeting was organized by calling Col. Wm. C. Osborn to the Chair, and Geo. A. B Dozier to act as Secretary.

After a few chaste, cogent and well directed remarks, explanatory of the meeting, by M. J. Crawford, Esq., a motion was submitted by the same, that the Chair appoint a committee of seven to draw up and report appropriate Preamble and Resolutions. Whereupon, Messrs. B Henry, B. Ligion, J. Brooks, Hatcher, Zachry, Trammell and Crawford, were appointed said Committee, who, having retired, returned and reported, through M. J. Crawford, Esq., the following

PREAMBLE AND RESOLUTIONS.

When real distress pervades a community, it is proper that individuals should assemble together and consider the causes producing such effects, and endeavor to remove them if it be in their power to do so. We are satisfied that for almost every evil, there is some corresponding remedy that may be used to effect its relief. The people of the Southern States have engaged all their labor in the production of cotton, with the exception of barely a sufficient supply of breadstuffs whereon to subsist. This has been the means of bringing into the country by far the greatest proportion of money that is or has been in circulation, whereby persons are enabled to meet their engagements; but the present price of this great staple and the prospect of its not advancing, demands from every one a serious consideration as to what course they should pursue. There is not a cotton planter but that could give the reason for the decline in this article; yet they are all satisfied that individual exertion and direction to their own labor, could effect no beneficial result; and hence no effort is made to accomplish that desirable object. Every one must understand that the allusion is to the overwhelming quantity which is produced, and so very far surpasses the demand—the man who cannot see the truth of this, must certainly be destitute of both reason and common sense. The remedy suggests itself to all, at a glance; yet, as has been before said, individuals can effect nothing, and it depends entirely upon the co-operation of the mass of cotton growers, whether or not they will pursue the suicidal course heretofore adopted. Another suggestion as to its use and consumption at home; the immense quantity of money paid out for bagging and rope, with which we bale our cotton, might be retained within the limits of our own State, by using the bagging and rope made from the cotton—and it is generally admitted to be equally as good as any other. The quantity of cotton thus manufactured would lessen the quantity for exportation astonishingly, and consequently advance the price in proportion to the diminution. Many individuals, no doubt, may apprehend that cotton thus put up for market would not command so good a price; but in this they are mistaken, for those persons engaged in selling the various other kinds of bagging and Rope would no doubt diminish the quantity usually ordered, were it unsaleable. Upon these subjects much more might be said; but experience is the best teacher, in which we have taken some lessons.

Wherefore, be it Resolved, That the planters of Harris county, here assembled, do agree to diminish the quantity of cotton by each of them raised, at least so far as to produce all other articles necessary for home consumption, and to supply those of our own County not engaged in agricultural pursuits, thereby preventing the annual transportation of large quantities of money to other States.

Be it further Resolved, That we will use, in the preparation of our cotton for market, the bagging, rope and twine made of cotton; provided we can purchase upon as good conditions as we could the various other kinds used.

Be it further Resolved, That we recommend to the other Counties to adopt some measures relative to these subjects.

These being submitted and adopted without dissension, on motion it was requested that they be published. WM. C. OSBORN, Ch'n.

GEO. A. B. DOZIER, Secretary.
Harris Co., Ga., Jan. 7, 1845.

P. S.—There seems to be prejudices existing in reference to these meetings, arising from mistaken notions as to their object. A goodly number did not attend in Hamilton from other causes, thinking the object was to form a binding agreement upon them to curtail their crops of cotton to a certain standard, when, in truth, it was but a suggestion of wisdom and economy to that false obtainment that looks to cotton as the King purchaser of all things. G. A. B. D.

To Census Takers.

The following letter to the editors of the Southern Recorder, from R. S. HARDWICK, Esq., who has been appointed to take the Census of Hancock county, is well worthy the consideration of those officers in the other counties of the State, and we commend it to their attention, with the sincere hope that they will all adopt his suggestions:

To Messrs. Grieve & Orme:

GENTLEMEN:—I have been appointed by the Inferior Court of Hancock county to take the census, and in making out my book after the form given in your paper, I find it will not give me a great deal more trouble to add a few more columns that will give us some important information on the agriculture of our State, *provided* it could be taken in all the counties. Whether others do it or not, I intend to do it in Hancock, that our people may know how much money they are sending abroad for articles they might make at home. I am of opinion, if the papers in the State were to show the importance of such information, that the persons appointed in the various counties would cheerfully do it; and I know of no persons better qualified than yourselves to bring this subject before them, and urge your brother editors to do likewise.

The columns that I have added to my book are as follows: 1st.—Number bushels Corn raised in 1844; 2d.—Number bushels Wheat, do.; 3d.—Number bushels Oats, do.; 4th.—Number lbs. ginned Cotton, do.; 5th.—Number lbs. Pork, do.; 6th. Number lbs. Pork bought, not raised in Georgia, do.; 7th.—Number lbs. Flour bought in 1844, not raised in Georgia; 8th.—Number Horses and Mules bought, not raised in Georgia, from 1st April, 1844, to 1st April, 1845; 9th.—Amount paid for Horses, Mules, Pork, and Flour, not raised in Georgia, between 1st April, 1844, and 1st April, 1845.

In those counties where they grow Rice and Tobacco, they might be added and Oats left out. I am clearly of opinion, if the true amounts could be ascertained, that our people pay out for articles that they might raise, that it would astonish us, and readily discover to us one of the causes of our pecuniary distress; and perhaps be the means of diverting us from our long established and ruinous practice of making cotton to purchase that which we could more easily raise than cotton. It may be that I have more laid out in my book, than many of those appointed would like to be at the trouble of preparing for and taking; but I consider them all useful, and am induced to do it for the benefit of agriculture in my own county. I hope, gentlemen, you will agree on the importance of the subject, and bring it before those persons appointed. Respectfully,

Sparta, Feb. 10, 1845. R. S. HARDWICK.

LAW FOR THE PROTECTION OF FRUIT.—Another subject demanding the immediate attention of our Legislature, and necessary to be urged by petitions, is, the passage of a law making the robbing of gardens and fruit yards a penal offence—or in other words calling it legally what it is in reality, *stealing*. As the law stands, we are told that this is not a *crime*, but an offence or trespass, for which we may bring suit and recover the amount of actual damage—which in effect is found to be not worth the trouble of prosecution; and hence, the law *encourages* this species of plunder, and serves to prevent many from cultivating choice fruit, who would otherwise do so.—*Ohio Cultivator.*

From the Albany Cultivator.

Mr. Colman's European Agriculture.

The second part of this work has made its appearance. The great difficulty of procuring the information sought, in an exact and authentic form, amidst the embarrassments and inconveniences which surround a stranger, are mentioned as reasons why this portion of the work has been so long delayed. Mr. Colman says he cannot promise his third and fourth numbers at any particular time, but assures us that no unreasonable delay shall be permitted. He has yet to visit Ireland, some of the counties of Scotland, the dairy portions of England, and the flax and hop districts. In the spring he intends to visit the continent, and hopes to be able to return to this country in autumn.

The first division of the number before us, is devoted to a continuation of remarks on the *Allotment system*. Under this head, many useful facts are given, showing the large amount of sustenance which the soil, under proper management, is capable of yielding—though, as Mr. C. says, it is probable that the "utmost productive capacity of an acre of land by any crop has not yet been fully determined."

An instance is mentioned where a man has supported himself, wife and son, from two acres of land, for which he paid a rent of $15 60; and in the course of seven years saved enough from the produce of his two acres to purchase two acres at $141 to $192 per acre. In another case, six acres, under spade cultivation, is stated to have given an average of fifty-two bushels of wheat per acre. Another witness brought before the Parliamentary committee, testified that on the estate of Lord Howard, Barbot Hall, Yorkshire, twenty-eight bushels of wheat had been obtained from a quarter of an acre; being at the rate of 112 bushels per acre. Mr. Colman thinks, however, that the accuracy of this statement may be considered doubtful.

At Horsham, in Sussex, some seed wheat, brought from Australia, was sown in rows 9 inches apart, and hills 6 inches apart, only one seed in a place. At this rate it took 9¼ lbs. seed per acre—at 63 lbs. per bushel, one bushel of seed would plant more than six acres. The yield of this wheat was at the rate of 71 bushels per acre. Some of the straw was six feet high.

A laborer, John Harris, in Sussex, produced the following crops from his allotment. "One acre and 12 rods, wheat, 53 bushels; half an acre of oats, 61 bushels; 30 rods of barley, 13½ bushels; 20 rods of peas, 4½ bushels; one acre of potatoes, 404 bushels; half an acre of turnips, 150 bushels; 16 rods of carrots, 3⅛ tons; 15 rods of mangel-wurtzel, 3 tons. The rest of his land was occupied as green food for his cows, such as cabbages, rye, clover, tares, &c. He kept two cows. He had from eight to twelve pigs all winter, and they consumed all his potatoes, and his turnips, mangel-wurtzel, and carrots, were given to his cows. He fattened 20 stone, or 960 lbs. pork, which he sold to the butcher. He sold 6 shoats at 3 months old, for store, and one pig for roasting; he also sold 2 sows in pig for $12.25."

An instance is mentioned where a man in Sussex, John Piper, who occupied four acres, and kept two cows, worked one of the cows in a cart, by which he makes an annual saving of $24. Notwithstanding the cow is worked, "she makes *eight pounds* of butter a week, besides furnishing some milk for the family."

Great pains are taken in all cases to save the manure. Nothing is wasted. The animals are stall-fed, and only turned into a yard a few hours a day for exercise. Brick or stone tanks, well cemented, are sunk near the cow-stables and pig-sties, for the reception of all the liquid manure. "The contents of these tanks, on becoming full, are pumped into a small cart with a sprinkling-box attached to it, like that used for watering streets in cities, and distributed over the crops, always with the greatest advantage, and with effects immediately perceptible." All which Mr. Colman saw, convinced him that there is no necessity for impoverishing the soil, but that under the right management, it will keep itself in condition, and be ever improving. The allotment system, though so evidently beneficial to the poorer classes, is strongly opposed by the farmers in general. In relation to the causes of this opposition, it is alleged that the farmers are not willing to lessen the dependance of the laborers on them for support—that the great crops obtained under such nice cultivation, contrasted with those of the farmer, tend to throw the latter into the shade, or by proving what the land is capable of producing, may induce the landlords to raise their rents. Besides, it is said the farmers are unwilling to see the laborers appear in the markets in competition with themselves. Mr. Colman observes that whether these reasons actually exist or not, the "motives named, alas! are but too consistent with the weakness, and too often unrestrained selfishness, of human nature. Every man certainly has a fair right 'to live,' and the duty of every just man is to 'let live.' Blessed be the day, if come it ever should, when every man will learn that his own true prosperity is essentially concerned in the prosperity of his neighbor, and that no gratification on earth, to a good mind, is more delicious than that which is reflected from the happiness of another, to which he has been himself instrumental."

Some of the allotments are managed by men who act in the capacity of school-teachers, and the scholars, who are boys from eight to fourteen years of age, perform the labor of cultivating the crops—working on the farm a given number of hours each day in return for their instruction. The system works well, both for the boys, and the condition and product of the grounds. Yet Mr. Colman feels constrained to add his "strong conviction that the education of the laboring classes is not viewed with favor by those who move in a higher condition of life." "Every approach, therefore," he continues, "in this direction, is likely to be resisted; and this feeling of superiority pervades, with an almost equal intensity, every class in society, above the lowest, from the master of the household to the most menial beneath whom there is any lower depth. Education is the great leveller of all artificial distinctions, and may therefore be well looked upon with jealousy."

Quantity of Seed per Acre.—Under this head we find also many useful facts and experiments. The English farmers generally practice very thick sowing, and it is the opinion of some very judicious cultivators, that a very large portion of the seed may be saved, and quite as large, if not larger, crops be obtained, as there are now. Some experiments strongly support this opinion. The practice in England is to sow from 2½ to 3 bushels of wheat per acre. One man has reduced his quantity to only *three pecks* per acre. He, however, drill and hand-hoes every thing, clover seed excepted. He sows one and a half bushels of rye, two bushels of oats, seven pecks of barley, and two bushels of peas per acre. In cultivating cabbages, he allows one to three square feet. He has produced 40 bushels of wheat, 104 bushels of oats, and 40 bushels of barley, to the acre. There is no doubt that by substituting the drill, for the broadcast mode of sowing, a large portion of seed might be saved.

Steeping Seeds.—Considerable has been said, during the past year, of a mode of steeping seeds, introduced by Mr. Campbell, of Scotland. Mr. Colman introduces one or two letters from Mr. Campbell in reference to this subject. The steeps he employs, are sulphate, nitrate, and muriate of ammonia, nitrates of soda and potass, and combinations of these. One experiment given, is in substance, the following: Some earth was dug up 6 feet below the surface, which was totally destitute of organic matter. It was sown with seeds which had been soaked in these solutions, and produced plants with seven or eight stems each, while plants from the unprepared seeds produced no more than three stems each. They had not reached maturity when this statement was given, and of course, the relative yield of grain could not be told.

Spade Husbandry.—This mode of cultivation seems to be extending itself in Great Britain, and under the cheapness of hand labor which there prevails, is found fully remunerating. The principle is the same as that of subsoil plowing. The best tool for the work, is a three pronged fork, 14 inches deep, and 7½ inches wide. This works easier than a spade, and pulverizes the ground better. Though, as Mr. Colman observes, spade husbandry cannot be generally introduced into the United States with advantage, yet he says there are some cases in which it might be found profitable, such as on farms where the poor are kept. In England, no farm is ever connected with a pauper establishment, and some caution is there used, lest those establishments be found too comfortable and attractive. Mr. Colman cites the example of a man in New England, who from only seven acres of land, sells annually $2,500 worth of produce.

Condition of Laborers.—Mr. Colman says, "it is with England a question of tremendous importance, what is to become of the vast accumulations of the people, which are continually increasing here at the rate of from seven hundred to a thousand per day. * * * The subject, it appears to me, and perhaps wholly from my being unaccustomed to a condition of things in any degree resembling it, is daily assuming a fearful aspect; I do not mean danger to the government, for the government seems never to have been stronger, but fearful in its bearings upon the public peace, the public morals, the security of property, and the state of crime." Mr. C. does not pretend to offer a remedy for this state of things, but seems to think the allotment system the best which has yet been devised, as it is, at all events, capable of improving, to some extent, the laborer's condition.

Progress of Agriculture.—Under this head, Mr. Colman gives an interesting description of the great improvements which have been made and are still going forward in England, by means of draining, irrigation, &c. Of the *live stock*, he speaks in the highest terms, but does not go minutely into this subject, intending to take it up by itself hereafter. He speaks not of the cattle as seen at the cattle shows, but as they are seen every Monday in the Smithfield market, and at the other smaller markets and fairs in various parts of the kingdom. He says—"here are cattle and sheep of several distinct breeds, and all of remarkable excellence of their kind; I do not say perfect, for that, in almost all cases, would be assuming too much, but leaving very little to be desired beyond what has been attained. Their condition and form, their symmetry, their fatness, are admirable; and each breed is seen retaining its distinct properties; and what is most remarkable, showing how much can be done by human art and skill, in improving the animal form and condition, and bringing it to a desired model."

Application of Steam to Agriculture.—The application of steam to the plow, so far as Mr. Colman has heard, has not been attended with much success. Steam engines are extensively used in some sections, for threshing grain. In the Lothians of Scotland, it is said that the use of steam power for this and other purposes, saves one quarter of the horse power required on the farm. A very important item, as the keeping of horse teams is the greatest single source of expense to the British farmer. A six horse steam power, usually threshes from 30 to 40 bushels of grain per hour. Mr. C. suggests that in the prairie districts of our western country, wherever coal can be had, steam power might be advantageously used for many farm purposes.

A very important use of steam power in Britain, is the conveying of live stock to market by means of steamboats and railroads. Cattle are brought in immense numbers to Smithfield market by these conveyances, without loss of

condition—some times the distance of seven hundred miles. Mr. C. thinks no parties have suffered injury from railroads. Contrary as it may be to all theories, the farmer near market is not injured, though the distant one is largely benefitted.

The Increase of Agricultural Products in Britain, is shown in a very striking light. The average importation of wheat into England from 1801 to 1810, when the population was set down at 17,442,911, would have given a fraction over one peck to each person. From 1811 to 1820, when the population was 19,870,589, the quantity imported would have given less than a gallon and a half to each person. From 1831 to 1835, the population was 25,000,000, and the quantity imported would have given to each person one gallon. Taking the three years, 1833-'4-'5, the importation would have allowed only one pint and one-fifth to each consumer. This will give some idea of the immense production and resources of that little island. Under a fast increasing population, as before mentioned, the dependance on foreign supply, has been constantly growing less.

Among the means of improvement, Mr. Colman remarks, that the Royal Agricultural Society is an efficient organ. It was instituted in 1837. It has begun the establishment of an agricultural library and museum, the object of which is to exhibit specimens of agricultural productions which are capable of preservation, seeds, plants, grasses, samples of wool, mineral manures, models and drawings of implements, &c. &c. Mr. Colman remarks that he has often urged the establishment of agricultural museums in the United States, especially in the capitals of the States. The suggestion is a valuable one.

The management of the Royal Agricultural Society at its exhibitions, is spoken of as admirable in many respects. Mr. C says:—"Every possible effort is made to secure an impartial decision among the competitors; for besides that they are not suffered by their presence to influence the examiners, the examiners themselves are selected from among persons as far as possible disinterested, and not likely to be influenced. They are chosen, likewise, with a special reference to their characters and qualifications, to the nature of the subjects submitted, and every pains is taken in this way, to secure the greatest aptness and talents. The name of the competitor is not given if it can be avoided, but only the number of the article presented. The rules of admission and competition, are stringent and absolute, and no exceptions are on any account allowed."

The Highland Agricultural Society of Scotland, and the Royal Agricultural Society of Ireland, are both spoken of as excellent institutions, similar in their objects and management to the Royal Agricultural Society of England.

Model Farms.—Mr. Colman notices some of these. He has visited that at Glasnevin, near Dublin, and furnishes some highly interesting particulars in regard to it. In connection with this establishment there is also an agricultural school, where young men receive such an education, theoretical and practical, as fits them to pursue the occupation of farming to the best advantage. The young men work in the field about 6 hours a day. Mr. C. had the gratification of listening to an examination of fourteen of these young men, brought out of the field from their labor and declares that "it was eminently successful, and in the highest degree creditable both to master and pupil." The products of this model farm, as given by the superintendant and teacher, are quite remarkable. Seven hundred and twenty bushels of potatoes per acre, are given as an average crop. The superintendant states that the largest crop he ever obtained, was in a field where the sets were three feet apart each way. Medium sized potatoes, planted whole, are preferred to cut ones The experiment has been made, and the difference between whole potatoes and cuttings was marked and obvious in favor of the former. The cattle on the farm are *soiled*. Italian rye grass is mentioned as one of the best articles for feeding. It is cut four times in a season, yielding at each cutting a good crop. Lucern is sometimes cut five times. The Scotch potatoe oat, and the Hopetown oat, are the varieties of this grain here raised. They yield an average of 80 bushels per acre, and weigh about 44 lbs. per bushel.

The typographical execution of the Second Part of Mr. Colman's work, is very perfect, and though the matter is somewhat miscellaneous, it is of a nature calculated to interest not only the agricultural, but general reader. The style is exceedingly chaste and agreeable, and a most beautiful moral tone pervades the whole. His remarks on the condition of the laboring classes in England, show how vastly superior are the advantages of that class in this country.

From the Albany Cultivator.

The Artichoke.

Several trials which we have known made with this root, indicate that it is one of the most valuable for stock, which can be cultivated. A few years ago, a gentleman of our acquaintance planted a small patch of rich ground with them. The produce was at the rate of 1,200 bushels per acre. They were principally harvested by hogs, which were turned in and allowed to root them as their appetite prompted. They gained well, with no other food, while the artichokes lasted. A great advantage of this root is, that it will lie in the ground without injury all winter.

Mr. Thomas Noble, of Massillon, gave us a brief account of a trial with artichokes, made by him in the past season. In April, 1844, he planted two acres with this vegetable. The ground was of medium quality. The artichokes were planted in rows two a half to three feet apart—using a little more seed than is commonly used in planting potatoes. As soon as the frost was out of the ground last spring, (1844,) the digging of them was begun and continued as the stock required. The produce of the two acres was 1,500 bushels. They were fed principally to sheep, though some were given to cattle, horses and hogs. All animals ate them well, seeming to prefer them to turnips. While the sheep were being fed with them they were pastured on growing wheat and clover. The shepherd thought the wheat and clover were sufficient for them, as there was a full "bite," and he accordingly discontinued the artichokes. The ewes fell off in their milk, and the lambs soon showed that they were not doing so well. The artichokes were again given, and they soon did as well as ever.

Mr. Noble also used the *tops* for fodder. He cut them in October, just before frost came, dried and housed them. They were fed to the stock in winter, and were evidently preferable to corn fodder.

Mr. N. is so well pleased with his artichokes, that he is raising them this year on a larger scale. They require but little cultivation; it being only necessary to keep the ground clear of weeds till the artichokes get a good start.

Mr. T. M Johnson, of Greensborough, Alabama, lately informed us, that he is this year growing thirty acres of artichokes. He considers them the most profitable vegetable he can raise. In that climate they can be dug at any time in the winter.

There are several varieties of artichokes, but that called the Jerusalem artichoke—*Helianthus tuberosus*—is considered the best. From the fibres of the tops or stems, a cordage is sometimes manufactured in some parts of Europe.

A Cure.—It is said that the syrup produced by sliced raw onions, with loaf sugar grated between them, and simmered before a fire, is a cure for colds and hoarseness. It should be taken just before going to bed, and the feet well roasted at the same time.

To secure handsome Balsams.—Carefully pick out from the seed-bed all plants with *red* stems, and leave those with *white* stems.

From the Farmers' Cabinet.

A Warm Bed for Pigs.

I very well remember a saying of an old gentleman, an excellent farmer, that if you would make a hog profitable, you should not let him ever see a winter: and I think I have satisfied myself, that spring pigs well kept and nursed, are far less expensive, and yield more in return for their keep than those which are fifteen or eighteen months old. But there is one thing quite certain; if we prefer our store hogs to come in the fall, we ought to be careful to keep them through our long, cold winters, both warm and dry. Every observant farmer knows that if his cattle are not sheltered from the cold weather and storms, they will require much more food to keep them in tolerable order, than if they are kept warm and comfortable. Just so it is with pigs—if they are suffered to run over your premises in the snow and sleet, with their legs and snout as red as the gill of your gobler, without a warm and dry bed of clean straw to resort to when they choose, they will not only in all probability come out with *mange* in the spring, but every grunt they give will convince you that all the food they have devoured, has been thrown away; for shoats that have a cold, damp, comfortless bed, will get mangy, and *mangy* pigs cannot grow. Let any one who has a mind to try the experiment, take two pigs of the same litter, suffering the one to run as above, and let the other be well housed, and well fed, and it will be found that the superior growth of the latter will pay for the care bestowed upon him, with good interest. Hogs that are confined, and cannot get to the earth, will frequently be benefitted by having a little charcoal, soft brickbats, or soft wood thrown into them, and a trifling quantity of brimstone mixed in their food occasionally, is an excellent thing. The hog has the credit of being a dirty fellow—but we should remember that he likes to be dirty in his own way, and for his own pleasure: he neither prefers to live cold, nor in filth—still less does he choose to be half fed. Dr. Franklin's man said the hog was the only gentleman in England, because he alone was exhonorated from labor. If this be so, surely he ought to be well fed and well housed in America. I entirely believe that the same amount of food that will barely carry a pig through the winter with bad management, will, with good, prudent treatment, keep him growing, and in the spring you have something to build upon, that will by and by make you a solid porker, who will do credit to your stye.

Newark, N. J. Essex.

Farmers' Boys, do you hear that?—The following is the postscript of a letter from a post master in a neighboring county.—*Ohio Cult.*

"I was 'raised' a farmer, and pursued that business till 1831; since which time I have been engaged in mercantile operations, and part of the time largely; but I shall never be contented till I get on to a farm again. It is the most beautiful and healthful occupation in the world; and yet how many of our young farmers are discontented, thinking if they were merchants they would live so much easier and happier! This is a grand mistake; I have tried both, and know it to be so from experience. I intend closing up as soon as I can with safety, and get me a farm on which to spend the remainder of my life.

"Yours, G."

Farmers.—H. Colman, in comparing the business of the farmer with that of others, says: "I am anxious to assist the dignity of a pursuit which I regard among the most honorable, as it is among the most innocent and useful in life; and I would, if possible, soften its aspect and multiply its attractions to a large class of persons who have been accustomed to look upon it with indifference or disdain, but who would be sure to find in it, if ardently and intelligently pursued, health for the body, and peace and satisfaction—nay more, the strongest and most delightful interest for the mind."

Horticultural Outline.

AN OUTLINE of the first principles of HORTICULTURE, by JOHN LINDLEY, F R S &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.

(CONTINUED.)

I.—GENERAL NATURE OF PLANTS.

1. Horticulture is the application of the arts of cultivation, multiplication, and domestication to the vegetable kingdom. Agriculture and Arboriculture are branches of Horticulture.

2. The vegetable kingdom is composed of living beings destitute of sensation, with no power of moving spontaneously from place to place, and called plants.

3. Plants are organized bodies, consisting of masses of tissue that is permeable by fluids or gaseous matter.

4. Vegetable tissue consists of minute bladders, or tubes adhering by their contiguous surfaces, and leaving intermediate passages where they do not touch.

5. Tissue is called *Cellular* when it is composed of minute bladders, which either approach the figure of a sphere, or are obviously some modification of it, supposed to be caused by extension or lateral compression.

6. When newly formed, it is in a very lax state, and possesses great powers of absorption; probably in consequence of the excessive permeability of its membrane and the imperfect cohesion of its cells.

7. Cellular tissue, otherwise called Parenchyma, constitutes the soft and brittle parts of plants; such as pitch, pulp, the spaces between the veins of leaves, the principal part of the petals, and the like.

8. Succulent plants are such as have an excessive development of the cellular tissue.

9. It may be considered the most essential kind of tissue, because, while no plants exist without it, many are composed of nothing else.

10. Tissue is called *Woody Fibre* when it is composed of slender tubes, which are conical and closed at each end, and placed side by side.

11. Woody Fibre is what causes stiffness and tenacity in certain parts of plants; hence it is found in the veins of leaves, and in bark, and it constitutes the principal part of the wood.

12. *Vascular Tissue*, is that in which either an elastic, tough thread is generated spirally within a tube that is closed and conical at each end; or rows of cylindrical cellules, placed end to end finally become continuous tubes by the loss of their ends.

13. The most remarkable form of vascular tissue is the *Spiral vessel*, which has the power of unrolling with elasticity when stretched.

14. Other kinds of vascular tissue are incapable of unrolling, but break when stretched.

15. Spiral vessels are not found in the wood or bark, and rarely in the roots of plants.

16. Vascular tissue of other kinds is confined to the root, stem, veins of leaves, petals and other parts composed of leaves. It is not found in bark.

17. The common office of the tissue is to convey fluid air, and not to act as the receptacle of secretions.

18. Cellular tissue conveys fluids in all directions, absorbs with great rapidity, is the first cause of the adhesions that take place between contiguous parts, and is the principal receptacle of secreted matter.

19. Adhesion will take place at all times during the growing season, when the cellular tissue of two different parts, or of two different plants, is kept for some time in contact; but as none but tissues of nearly the same nature will adhere, grafting and budding, which are caused by the adhesion of contiguous parts, can only take place either between different varieties of the same species, or between nearly related species; and even then only when the corresponding parts of the scion or bud, and the stock, are placed in contact

20. Woody fibre contains fluid in the direction of its length, gives stiffness and flexibility to the general system, and acts as a protection to spiral and other delicate vessels.

21. Spiral vessels convey oxygenated air.

22. Other vessels probably conduct fluid when young, and air when old.

23. As the bodies of which all Tissue is composed are perfectly simple, unbranched, and regular in figure, having when elongated, their two extremities exactly alike, they are more or less capable of conveying gaseous matter or fluids in any direction: and, consequently, a current may be reversed in them without inconvenience; hence, inverted cuttings or stems will grow.

24. All parts of plants are composed of tissue, whether they be soft, as pulp, or hard, as the bony lining of a peach.

25. With regard to Horticultural operations, the parts of plants should be considered under the heads of *Root* (II); *Leaf-buds* (IV); *Leaves* (V); *Flowers* (VI); *Sexes* (VII); *Fruit* (VIII); and *Seed* (IX.)

II.—ROOT.

26. The Root is the part that strikes into the earth when a seed begins to germinate and which afterwards continues to lengthen beneath the soil.

27. It is also the part which is sometimes emitted by the stem, for the purpose of absorbing nutrition from the atmosphere; as in Ivy, Air-Plants, Vines, &c.

28. It is distinguished from the stem by the absence of leaves in any state, of regular leaf-buds (IV); of evaporating pores, or stomata (131); and of pitch in Exogenous plants.

29. Therefore, such underground bodies as those called Tuber (61) in the Potatoe, Bulb (96) in the Onion; and solid Bulb or Cormus (61) in the Crocus, are not roots.

30. The office of the root is to absorb food in a fluid or gaseous state, and also to fix the plant in the soil, or to some firm support.

31. The latter office is essential to the certain and regular performance of the former.

32. It is not by the whole of their surface that roots absorb food; but only by their young and newly formed extremities, called *Spongioles*.

33. Hence the preservation of the spongioles in an uninjured state is essential to the removal of a plant from one place to another.

34. A Spongiole consists of very young vascular tissue (12), surrounded by a very young cellular substance, (5).

35. It is therefore one of the most delicate parts of plants, and the most easily injured.

36. Hence whatever is known to produce any specific deleterious action upon leaves or stems, such as certain gases (298), and mineral or vegetable poisons, will produce a much more fatal effect upon the spongioles.

37. These organs have no power of selecting the food, but will absorb whatever the earth or air may contain, which is sufficiently fluid to pass through the sides of their tissue.

38 So that if the spongioles are developed in a medium which is of an unsuitable nature, as they will still continue to absorb, they cannot fail to introduce matter which will prove either injurious or fatal to life, according to its intensity.

39. This may often explain why trees suddenly become unhealthy, without any external apparent cause.

40. Plants have the power of replacing spongioles by the formation of new ones: so that an individual is not destroyed by their loss.

41. But this power depends upon the co-operation of the atmosphere, and upon the special vital power of the species.

42. If the atmosphere is so humid as to hinder evaporation, spongioles will have time to form anew, but if the atmosphere is dry, the loss by evaporation will be so much greater than can be supplied by the injured roots, that the whole system will be emptied of fluid before the new spongioles can form.

43 This is the key to Transplantation, (XV.)

44. As the roots are destitute of leaf buds, (IV,) and as leaf buds are essential to the multiplication of an individual, (108,) it should follow that roots can never be employed for the purpose of multiplication.

45. Nevertheless, roots, when woody, have, occasionally, the power of generating adventitious leaf-buds, (IV,) and when this is the case, they may be employed for the purpose of multiplication; as those of Cydonia, Saponica, &c.

46. The cause of this power existing in some species, and not in others, is unknown.

47. It is therefore a power that can never be calculated upon; and whose existence is only to be discovered by accident.

48. Although roots are generated under ground, and sometimes at considerable depths; yet access to a certain quantity of atmospheric air appears indispensable to the healthy execution of their functions. This is constantly exemplified in plants growing in the earth at the back of an ill-ventilated forcing-house, where the roots have no means of finding their way into the earth on the outside of the house.

49. It is supposed by some that the introduction of oxygen into their system is as indispensable to them as to animals.

50. It seems more probable that the oxygen of the atmosphere, seizing upon a certain quantity of carbon, forms carbonic acid, which they absorb, and feed upon.

51. It is at least certain that the exclusion of air from the roots will always induce an unhealthy condition, or even death itself. This may be one of the reasons why stiff, tenacious soils are so seldom suited to the purpose of the cultivator, until their adhesiveness has been destroyed by the addition of other matter.

52. Spongioles secrete excrementitious matter, which is unsuitable to the same species afterwards as food; for poisonous substances are as fatal to the species that secrete them as to any other species.

53. But to other species the excrementitious matter is either not unsuitable, or not deleterious.

54. Hence, soil may be rendered impure (or, as we inaccurately say, worn out) for one species, which will not be impure for others.

55. This is the true key of the theory of rotation of crops.

56. This also may serve to explain in part why light soil is indispensable to many plants, and heavy or tenacious soil suitable to so few: for in the former case the spongioles will meet with little resistance to their elongation, and will consequently be continually quitting the place where their excrementitious matter is deposited; while in the latter case, the reverse will occur. [To be continued.]

A FACT FOR THE CURIOUS.—A. W. Palmer, of Cheam, in Surrey, England, tried a very striking experiment respecting the production of wheat. In July, 1841, he put one grain of wheat into a common garden pot; in August he divided it into four plants, and in three weeks again divided these into twelve plants; in September, these twelve were divided into thirty-two, which in November were divided into fifty; and he then placed them in the open ground. In July, of 1842, twelve of them had failed, but the remainder of them were healthy. On the 19th of August they were cut down, and counted 1972 stems, with an average of 50 grains to the stem—giving thus the increase of 98,600 grains.

MILK.—Milk is a perfect food for a growing animal, containing the curd which is to form the muscles, the butter which is to supply the fat, the phosphates which are to build up the bones, and the sugar which is to feed the respiration. Nothing is wanting in it. The mother selects all the ingredients of this perfect food from among the useless substances which are mingled in her own stomach with the food she eats—she changes these ingredients chemically in such a degree, as to present them to the young animal in a state in which it can most easily, and with least labor, employ them for sustaining its body—and all this she begins to do at a given and appointed moment of time. How beautiful, how wonderful, how kindly provident is all this!—*Johnston.*

Circular of Messrs. Skinner and O'Rielly.

AGRICULTURAL IMPROVEMENT IN VIRGINIA, MARYLAND, CAROLINA, ETC.

In unison with the views of sundry Southern gentlemen who are warmly interested in agricultural improvement, and in accordance with the inquiries of various friends in the Northern States, the undersigned are collecting statistics illustrative of the vast field for enterprise presented by the uncultivated lands of the South. The dilapidated estates, as well as the virgin soil, in various sections of the old Southern States, present attractions which would not long be slighted, were the facts generally known. Thousands of enterprising emigrants from the Northern States would annually flock to Virginia in preference to the Western country, were her advantages presented in a manner calculated to arrest their attention At present, all the Guide-Books for Settlement point exclusively to the *West:* while examination and reflection will probably satisfy any intelligent man that the world nowhere presents a better field for enlightened enterprise than is furnished by the millions of acres which now invite improvement in the high-land regions as well as in tide-water sections of the "Old Dominion."

The natural advantages of Virginia are unsurpassed by those of any country in the world. The richness of the soil in large sections of the commonwealth still defies the exhausting influence of improvident cultivation. Even the "worn out estates," as they are sometimes styled, abound generally with mineral and fossil remains, admirably calculated to replenish the soil wherever mismanagement has robbed it of qualities essential to successful farming. The land abounds, not only with these manures, but with other mineral treasures of incalculable value. The mountains embowel iron and coal, transcending in quantity any possible requirements of the largest population which could be crowded for centuries within that ancient commonwealth; while the lime, marl and other natural fertilizers, abundant nearly every where in the State, furnish inexhaustible and cheap resources for rendering Virginia one of the richest agricultural regions of the earth. The Atlantic and the Western waters, with numerous bays and rivers penetrating various sections, furnish facilities for commerce with other countries, as well as for easy communication between the people in nearly all quarters of the Commonwealth. The value of the fisheries is largely experienced, not merely in the tide-water region, but to a great extent through the interior; and what territory anywhere surpasses the Virginia mountains in qualifications for sheep husbandry? Superadded to all these considerations, and equally important with any of them, is the mildness of the climate—an attraction alone sufficient to render Virginia desirable to thousands of enterprising settlers, who, when abandoning their homes in the North, would prefer the Southern temperature if it could be enjoyed under advantages like those presented by the Western States now most rapidly accumulating immigrant population.

The men of Virginia, familiar with the career of Washington, need not be told that, with such extraordinary combinations of advantages, the "Old Dominion would not now be *razeed* in the scale of States, if the spirit which influenced that illustrious patriot had been continuously applied for the last half century towards the advancement of that Commonwealth in the career which he foreshadowed for her in Agriculture, Commerce and Manufactures, additional to her political renown.

The intercourse and correspondence with which the undersigned have been favored by many distinguished Virginians, and also by gentlemen of other States, such as Maryland, Kentucky, the Carolinas and Tennessee—together with personal observation and much inquiry among the farming community—induce the belief that *a systematic effort for promoting the sale and settlement of uncultivated lands in those States*, may now be made with strong hopes of successful results. Under these circumstances, it is deemed essential, by various Southern gentlemen, as well as ourselves, to collect all practical information concerning the condition and price of lands in the regions above mentioned, and all other information which the friends of improvement may choose to communicate, for the purpose of extending a knowledge of the advantages presented for settlers. The gentleman to whom this circular is addressed may therefore promote the object, if he approves of it, by communicating to the subscribers such facts as he may deem proper concerning the number, extent, soil, condition, price and products of estates for sale in his vicinity, with the names of the owners or occupants, including particulars concerning proximity to watercourses and mineral manures; and maps of the land should, when convenient, accompany the descriptions. Where the lands are new, whether in the mountains or otherwise, it is desirable to know the probable advantages for sheep husbandry and grazing generally, as well as for grain-growing, especially as the highlands of the Southern States are beginning to attract, as they may be made to attract largely, the attention of wool-growers and graziers—while the vast water-power abounding in those regions, amid inexhaustible supplies of fuel, iron, &c., should be specified, as offering multitudinous inducements for extended manufacturing operations.

Gratified to find that the views here briefly expressed have met with the cordial concurrence of gentlemen from the several States above mentioned—gentlemen whose approbation encourages this mode of acquiring and diffusing information concerning the inducements for enterprise presented by the uncultivated lands within the borders of those States—the undersigned will close for the present, by mentioning that their connection with the friends of agriculture in various quarters satisfies them that the diffusion of accurate information is only necesssary to attract enterprising settlers, whose capital and industry would speedily bring into profitable cultivation millions of acres scattered in tracts of various sizes over all sections of Virginia and the adjoining States.

JOHN S SKINNER, *Washington*,
(Former Editor of the American Farmer.)
HENRY O'RIELLY, *Albany*.
(Of the N Y. State Agricultural Society)
December, 1844.

TO DESTROY LICE ON CATTLE.—Grease, fat, lard, or any oily substance, if applied to neat cattle infested with pediculi, will have the desired effect; it must be applied by being well rubbed into the hair on those parts where the vermin are found, and repeated until they are destroyed. Insects have no lungs, but breathe by spiracles or minute holes in their bodies, and if these spiracles are clogged with grease or fat, they become suffocated and die. Goose grease, hogs' fat, pot skimmings, will all answer the purpose, and may be obtained in any farmer's family without cost. Tobacco, also, will kill these vermin on cattle, by its operation on them as poison. A simple infusion of tobacco, applied warm and rubbed into the neck or dewlaps, or wherever found, so as to completely wet the hairs, and repeated at an interval of a few days, will destroy the nits and lice in a short time and at a cheap rate. The curry-comb should be used after the application.

SUBSOIL PLOWS.—In many soils, not otherwise rich enough for corn, it would be a good practice to make a furrow six inches deep, in the fall with a common plow, then let a subsoil plow run in this furrow ten or twelve inches more; and it would be still better to put cornstalks and other manure in this trench, and list it in, when thoroughly wet, with a small plow or hoe; the land to remain in this state till planting time. The subsoil plow is very valuable; by its use the soil will be less wet in great rains, and more moist in great drought. Where the subsoil plow is used, in comparison with only the common plow, the yield will be fifty per cent. more, and the crop in dry weather always green. The subsoil plow has doubled and frequently trebled the crops in England.—*Farmer and Gardener.*

CONTENTS OF THIS NUMBER.

The Southern Cultivator

Is published on the first of every month, at Augusta, Ga,

BY J. W. & W. S. JONES, PROPRIETORS.

EDITED BY JAMES CAMAK, OF ATHENS, GEO.

TERMS.—ONE DOLLAR A YEAR.

1 *copy, one year*..... $1 00 | 25 *copies, one year*...$20 00
6 *copies*, " ..... 5 00 | 100 *copies*, " .. 75 00

[All subscriptions must commence with the volume.]

THE CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to Agriculture, will be inserted for ONE DOLLAR for every square of ten lines or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance

☞ POST MASTERS are authorized to receive and forward money free of postage

☞ ALL COMMUNICATIONS MUST BE POST PAID, and addressed to JAMES CAMAK, Athens, Georgia.

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., APRIL, 1845. No. 4.

From the Albany Cultivator.

Agriculture and Rural Economy of the South.

DEAR SIR:—Press of business, alone, has prevented my carrying out my intention of addressing you, as I promised in my last, on various subjects of interest to us here; and in particular of replying to Mr. Camak's call for aid in introducing the olive to the south. He does me but justice in supposing that no effort on my part, within my power to make, would be wanting towards the introduction of any plant that would add to the wealth of my adopted country. Among others I have often thought and spoken of the olive; but felt so much discouraged by the fact that my father-in-law, Mr. Isaac Dunbar of this place, has repeatedly introduced varieties of that plant without success, the frost destroying them, that I entirely overlooked the extract in Kenrick's work. Since reading Mr. Camak's article, I am resolved to make an effort to procure the Nikita olive and give it a fair trial here. The difficulties, however, which a private individual has to contend with in such an effort, are very great. In my own case, the only course I can pursue, is to request my correspondents in Paris to make every exertion to procure some plants for me. If some others would do the same, we might, some one of us, ultimately succeed. I have long ceased to expect that the General Government will give any such aid to the farming interest.

That every effort should be made by the south, to introduce other staple crops than cotton, is very certain. The over-production is so great that prices cannot improve; at present prices this troublesome crop cannot be grown with profit—in fact not without loss—and the only possible means of lessening this over-production, is to induce the cotton planter to turn his attention to and employ a portion of his force in other crops, or in auxiliary branches of economical husbandry, if even these pay no better than cotton does now. Here it is that a State Agricultural Society *and farm*, liberally supported by the State, would give proof of their value. Those experiments in the introduct on of new staple crops could be tried there, which cannot be well done by individuals to any extent, with justice to themselves. Any planter can, however, after a few years, carry on upon his plantation many practices of economical good management—to some of which I will presently advert.

I prepared a series of resolutions some weeks ago, which I intended submitting to our Ag. Society at its business meeting after our last Fair. But so great was the political excitement at this time, that I regret to say a sufficient number of the members did not attend on that day to form a quorum. As another business meeting will be held about the time your January number will have reached us, when I intend bringing the matter forward, I will give you these proposed resolutions here:

"Resolved, That it is the opinion of this Society, that the present ruinously low prices of cotton, arise almost wholly from inordinate over-production.

"That a committee be appointed to prepare an address to the farmers of the cotton-growing region; setting forth the absolute necessity that exists for an entire change in the system of farming pursued among us, so as to lessen the quantity of cotton produced—to employ a considerable proportion of the labor of our slaves in the production of other staples; and of all the supplies necessary for the plantation which can be so produced, if not with profit, at least without loss.

"That they shall include, in their address, all the information they can procure as to the staple crops which may be so introduced; with short notices of the system of culture necessary for each; cost of production compared with cotton, &c.

"That the use of cotton bagging, in baling, be particularly considered; information acquired as to the cost, in plantation labor, of its manufacture; strength requisite, &c.; and the particular grounds that may exist for objections, if any there be, to its use.

"That they also inquire, whether the establishment of cotton factories generally within the cotton-growing States, would not have the effect of counteracting the combinations which are formed in the foreign markets to keep down the prices of the staple.—Whether, such a demand for provisions may not thus be created at home, as to render their production at least as profitable as that of cotton, and thus divert a considerable portion of the labor now employed in the over-production of the latter—And if, in the judgment of the committee, manufactories within the cotton region would produce these results, what measures can be best adopted to encourage their introduction.

"That they shall submit their address and report at the next regular meeting of this Society."

In all enlightened governments, but our own, agriculture receives powerful aid and support; not so much by means of protective duties and imposts, as by the wise measures taken for its relief when in any manner oppressed. Witness, in Great Britain, the frequent appointments of committees of the House of Commons, to examine into the causes of results the most trivial when compared with that now in question, and with power to call before them for information, individual and documentary evidence from every part of the country. Although we, in this country, have no such powerful aid given us, we might do much good by such a plan as this here proposed.

Some weeks ago, I had some inquiries made of me by a gentleman in Natchez, who informed me that he was one of a company formed with the view of shortly erecting an oil mill there; chiefly with a view to making castor oil. I assured him, at once, that the bean can be grown with profit by the planter; and promised to grow, next year, an acre or so, each, of the castor oil bean, sunflower, and Bene; also to try the Madia sativa, of which I have a small quantity of seed. In Illinois large quantities of the Palma Christi bean are grown, and the manufacture of castor oil is carried on with much profit. The farmers, there, so far as my recollection goes, found the bean a very remunerative crop. I neither remember the average yield per acre, nor the usual price, but have taken measures for refreshing my memory. Can you aid me? If you have files of the (Chicago) Union Ag. and Prairie Farmer, I think you will there find all the information wanted. It grows spontaneously along our road side, producing, I think, quite as good crops as those I have seen in Illinois. I have a variety of it in my garden of extraordinary and productive growth. A plant of it, which made its appearance in one of the borders, a volunteer, quite late in this present season, has attained a large growth. At five feet from the ground the stem is 15 inches in circumference; there it throws out three branches the tops of which are 17 feet from the ground, and spread to a diameter of 12 or 14 feet. Where the branches spring out, a spike of seeds has been ripe this three months; and now at the top of each of the three branches is a very heavily laden spike, the seeds in which are not quite ripe; though they certainly would have been had the seed been planted sufficiently early. The beans of this variety are very large. I find on trial that they weigh an average of six grains each. The stem and leaf-stems have a reddish tinge; the plant altogether forming quite a handsome tree. Last winter was so mild with us here that plants of this variety stood uninjured, and in the spring threw out multitudes of flower spikes. I am perfectly aware that a plant of such gigantic growth would be illy adapted to field culture, as a crop in rich land; I mention it merely as a proof that there is nothing uncongenial in our climate to the growth of the Palma Christi; and because I think that this sort would do well as an aftercrop, say on oat stubble; and then have abundance of time to ripen its seed.

The Bene grows vigorously, and produces an abundance of seed; so, I am told, does the Madia sativa, although I have no knowledge of it myself; the sunflower I know will do well—all of these yield a very large proportion of valuable oil.

I have grown a small crop of Havana tobacco this season, which is said to be of fine quality by those who profess to be judges. When properly cured and made into cigars a better opinion can be formed. I cut this three times, and each cutting was good; if planted early, and a handful of cotton seed or some other equally portable and effective manure hoed in round the plants at the second cutting, I have no doubt but four cuttings could be had at each season—the two last of course of inferior tobacco.

The gentleman before spoken of, Mr. Isaac Dunbar, has for many years made his own wine. That which he exhibited at our last Fair was pronounced decidedly superior to any he has before shown. I think it was the best native wine I have ever met with. Mr. D. has a vineyard of sufficient extent to make a few barrels of wine, and leave enough of grapes to give even his negroes a fair share. His favorite grape is the Herbemont Madeira—as being perfectly hardy and requiring but little attention. At our summer Fair, this season, one gentleman exhibited seven varieties of grapes, principally European sorts. The variety that does best with us, is one known as the *Jack grape*. What it is I can only guess at. The vine is of a vigorous, healthy habit; young wood having a reddish tinge, resembling the cigar box and Norton's seedling; the bunches quite large and shouldered; the berries, which are entirely without pulp, are of sizes varying from that of an eighty-to-the-pound rifle bullet, to that of an ordinary sized buckshot; juice a

rich claret color and very abundant; the flavor fine, with a delicious admixture of sweet and sour; and forming altogether, when fully ripe, a most delicious table grape. If Mr. Camak will inform me by letter or otherwise, how to forward to him, I will have much pleasure in sending a couple of plants, that he may test this fine fruit in his region.

When I have again leisure, I may have somewhat to say on the cultivation of the vine, through yours or some other journal. I will only now add, that *excessive* deep planting will assuredly prove injurious. Moderately deep planting, however, *the soil being of a proportionate depth*, is by all means advisable. With you in the north, even as far south as Cincinnati and Nashville, and in the colder districts of Europe, the vine is trained low that it may benefit by the reflection of the sun's rays from the earth; while here, and even in latitudes north of us, to avoid this, and to secure the full benefit of the shade afforded by its own foliage, and all the air possible, the vine requires to be trained high—over a ten or twelve feet arbor, if possible.

I must pass over the subject of "new staple crops," on which a lengthy series of papers might be written. Indigo has been successfully and profitably grown here—the sole objection to it being the difficulty of making sale of the entire crop without having to seek for a market. Madder, I am confident, would find its most congenial climate and soil here. It is a native of a southern clime, and requires just such a warm, light soil as we can here furnish it with.

Bread, meat and clothing, every cotton plantation *should and can* furnish for its own consumption, and even for sale, and yet grow as much cotton as should be grown. In fact, there is not a doubt, but if such a system could be generally introduced, cotton would again command a remunerative price. Other items should be included—comforts instead of blankets; leather for shoes and harness; tobacco for the negroes; bagging made at home, of cotton; hay grown for stock and for sale; all the mules and horses needed, raised at home; a flock of sheep kept, sufficient not only to clothe the negroes, but to afford a considerable return for wool and mutton; butter made for sale, the buttermilk being decidedly more wholesome for the negroes, young and old, than sweet milk, especially in summer, and any tidy old woman can easily make more in the dairy than in the field; and many other ways in which hands can be employed to at least *as great advantage and profit* as in the cotton crop—with the great additional advantage of thereby lessening the ruinous over-production of that staple.

I have already written you, thus far, a most egotistical letter; too much so; and yet I do not see how I can so well sustain my assertion, as to the practicability of this change in our system of farming, as by giving my own experience. True, this experience has not been great—but it has this advantage, that though but of three years standing, it has been acquired in the face of serious difficulties. I had every thing to buy but corn—and even some little of that. So, with your leave, I will continue as I have begun, and give you a little more of *Ego!*—premising, that in good and economical management, I am far, far behind many of the planters of this region, *as yet*.

Corn can be grown here quite as well as in N. York, notwithstanding the opinion of that *enlightened southern gentleman*, who made such wonderful discoveries relative to the climate of the south—see the garbled edition of Johnson's Farmers' Encyclopedia. I am now offering 200 bushels of corn for sale, being my surplus of this year's crop, over the requisite supply for that plantation. Wheat, also, will do well at least two seasons in three; if we had a sort sufficiently early to ripen before excessive warm weather, I do not believe this crop would be any more subject to failure than with you. The "Valparaiso," of which I received a small quantity of seed through the Patent Office, was entirely destroyed, this year, by rust. It tillered well, and the heads when coming in bloom, were very large. I mean to secure a supply of all Mr. Harmon's sorts against another season. Egyptian or winter oats do remarkably well. They are sown in September or October, and afford capital pasture all winter, and a fine yield of grain, ripe early in May. Forty bushels is spoken of as a good, fair crop: one bushel sown produced me twenty. I prefer this grain to rye. It commands readily from sixty cents to a dollar according to the supply. My pea crops, with the gleanings of the sweet potatoe lots, will fatten my hogs this year—a trifling quantity of corn *may* be needed. Of sweet potatoes, turneps, Irish potatoes, white beans, rice, hay, fodder, pindars, &c., I have hitherto found no difficulty in growing in abundance.

Cattle, unless where the range is extensive and good, or where the planter has formed good Bermuda pastures, I do not consider profitable stock here—at all events, by no means as much so as sheep, hogs or mules. To raise one's own meat, requires a good deal of care and attention—but it can be done profitably and advantageously on any cotton plantation. A little over two years ago, I commenced operations with eight thorough bred Berkshire sows, as many good common ones, and two or three fine boars, of different families of Berkshires, including imported Newberry. This fall I will kill a fair supply of meat, and offer some thirty or forty fine, young, in-pig sows for sale, being unwilling to kill them while they are so much needed in the south. I offer them at less than the price of a barrel of pork—$10. I lost, last spring, over one hundred pigs and shoats of a disease in the throat, caused, I believe, by their eating young cockle-burr plants. Such, too, is the opinion of my overseer who had charge of them—Mr. Hamilton—a very intelligent, observing man. When turned out of the field where these grew, the hogs ceased dying and got well—when put back there they became sick again, and many died off. In addition to this, I have lost, in spite of every precaution, a good many through my own and my neighbors' negroes—no matter how much meat they may get, both salt and fresh, the negroes have a particular liking for fresh pig, killed and cooked *on the sly*, as school-boys say. All this, however, *can* be prevented. And even supposing that from ten good sows, one hand devoting his entire time and attention to them and their produce, 50 hogs of 200 lbs. each can be killed per annum, that hand is doing a fourfold better business than at growing cotton. Moreover, the hogs being during the picking season in the pea field, the services of the hand can be had at that time, when they are most valuable. I think I can have two hands supply the slaughter pen with three hundred fine fat hogs, each year, and attend to the breeding and stock hogs also. I feed much cotton seed, thoroughly cooked, and a small proportion of meal, with salt and ashes added, and occasionally pumpkins and turneps, boiled with it—and with decided economy and advantage. For sheep, as I have often asserted, this is the finest country I have ever seen, and I think myself tolerably good authority in the matter. This, however, may very fairly form the subject of a separate article.

Clothing—this too, requires time and attention; but there is nothing else needed to enable any force of negroes to manufacture the material for their own clothing, *with profit* to their owners. During winter the women cannot be so well employed in any way as in spinning up the wool—particularly where a carding machine is accessible. One woman, keeping a spinning machine and a loom going all the year, would spin the warp and weave the cloth for a very large place. Those spinning machines are a great convenience—they spin six threads at a time—the gin saws taking the cotton from the seed—the brush placing it on the cards when ginned, where it is carded, and then spun direct from the cards, all at one operation. Mine was made by Pearce & Co, Cincinnati, and cost $130. We have now, in Natchez, a very excellent manufactory established, and now in the hands of a most energetic business man—Mr. McAllister, of the firm of McAllister & Watson—who is proving that such a concern will succeed in the South, afford a profit to the manufacturer, and be a great source of convenience and economy to the planter. Linsey, jeans, all kinds of cotton goods, including *bagging* and sacking, bale rope and twine, &c. &c. Also *burring* and carding wool at so much per pound. Mr. McA. began by pledging himself that he would manufacture for the planter, from his own cotton and wool, fabrics of any kind to cost him, at least, *no more* than he could buy it for of northern manufacture, allowing a fair price for the raw material. The cotton bagging, made for Mr. Isaac Dunbar, out of most indifferent cotton, worth perhaps one or two cents per pound, is a very superior article—better, in the opinion of many, than the hemp article. I have little doubt that the cotton shipped from Natchez will be, half of it, put up next year in bagging of cotton—if the planters consult their own interest they will do so. If all the cotton made in the Union was packed in this material, we would have the crop lessened or consumption increased rather, to the amount of 22,500,000 pounds, or 56,250 bales—being five yards of bagging, weighing 9 pounds, for two and a half millions of bales. Bale rope and twine would swell the amount to over 70,000 bales.

Mrs. A. is just finishing off a lot of over 50 double and single comforts for the negroes, in place of blankets, which cost an average of about $1.12 each—not including the labor of making, which in fact may be so much wet weather time of the women's labor saved, and it is well repaid in the difference in the cost of blankets. Had we not made comforts, I would have required over 45 pairs of blankets—difference, to pay for the making of the comforts, at least $120. This has been our first experiment in comforts, though some planters here have used them for many years. The use of comforts has other advantages—see the extra consumption of cotton—then the women are all taught to sew better than they would usually do.

Many other items of economical management of the plantation might be mentioned, each of sufficient importance for a separate article; but I must now close, with the hope that every planter who has the good of the south at heart, and who is desirous of lessening the overproduction of our main staple, will never cease to act, to talk and to write with that object in view, until public attention is drawn effectually to it. Yours, &c., THOMAS AFFLECK.

Ingleside, near Washington, Miss., Nov. 16, 1844

CORN-STALK SUGAR.—In our May number of the volume for 1844, we gave a communication on this subject from Mr. John Beal, of New Harmony, Indiana. It appears that Mr. B. has been still more successful the present year than he was last. We are informed that he has made three hundred and ninety-five pounds of good sugar this season, from the corn stalks which grew on three-quarters of an acre, which is at the rate of five hundred pounds per acre. His plan is said to be as follows: "When the ears begin to form they are pulled off. When the leaves are dead about half way up, the stalk is stripped of leaves, cut up at the root, the top cut off, and then ground in a sugar mill. Twenty stalks will yield about one pound and a half, and of this three-fourths is grained sugar. Mr. B. made eighty pounds in a day, with a simple apparatus of his own construction. Five hundred pounds, at four cents per pound, is twenty dollars per acre. It would have produced, say fifty bushels of corn, at twenty-five cents, or twelve dollars and a half.—*Albany Cultivator*

EGYPTIAN COTTON.—Mr. White, of Louisiana, has on his plantation a cotton stalk, from Egyptian seed, about fifteen feet in height. Mr. White obtained twenty seeds, gathered from the garden of the Pacha. He thinks, if carefully managed, it would probably yield from 2500 to 3,000 lbs. of seed cotton to the acre.

From the Albany Cultivator.

Practical Husbandry.

Improvement of Worn Out and Naturally Poor Lands, Old Fields, &c., in the Middle States.

I intimated in a late paper in the Cultivator, (vol. 1, p. 314,) that I would shortly give the readers of that excellent work an answer to the question *how* the improvement of the kinds of land mentioned in the heading of this article, could be accomplished in the cheapest way. I now proceed to the fulfilment of my promise. Land is poor or rich from various causes. It may be poor naturally, from being deprived of the accumulation of decomposed organized matter, by the washings of rain, the overflowing of streams, &c., and by its own gravelly and porous nature, admitting the upward filtering of spring water, as is the case in low gravelly bottoms. It may also be poor from the too large a portion of iron in its composition. But the most universal cause of poverty of soil, is EXHAUSTION, from over-cropping, taking always, and returning nothing; as was so generally the practice in old times, and is too much the practice now in all the middle States. In a former paper I have expressed the opinion that a man may purchase and improve a piece of this poor or worn out land cheaper than will be the cost of removal to, and purchase of a piece of land in the west, especially when the sacrifices incident to such removal are taken into the account. I most sincerely believe in the truth of this proposition. But let us proceed to the subject—the HOW, not the *why*, this land should be improved.

The first object to be attended to in the improvement of land, is the grubbing up and clearing off every tree and shrub that is not wanted. Let this be done at the beginning. Allow no clumps or clusters of bushes or briars, or single ones either, to remain in the field. The next thing is ditching and draining of all sunken and boggy places, if such exist. Very often the simple plow furrow will answer, but sometimes a deep ditch must be dug. If it be deep enough, a blind ditch should always be preferred, so that you may cultivate the land over the ditch, and also save your land the inconvenience of open ditches. Having grubbed and ditched, and thus drained the land, the next object is to ascertain the quality of the soil, all parts of it. You may find that the low places you have drained are composed of hard clay. Some of the upper or higher places may be too sandy. You will in such case, employ your carts in carrying clay to the sandy parts, and return with sand to the clayey parts; and be very liberal in your exchanges, too. You may spread the clay at once, or allow it to remain a winter in cart load heaps, and spread it in the spring. The sand may be spread, of course at once. All this is merely getting the land ready. A carpenter builds his shop, and "gets out" his stuff, before he thinks of "going to work" at his trade. So does every other artisan or mechanic. Why should a farmer not, also, before he goes to work to make money and a living, first "get his shop in order?" Having properly grubbed, drained, and mixed the soil, the next thing to be done is to ascertain the quality of the whole. It most probably wants lime to make it complete. Take a handful here and there from the whole field, say twenty handsful in all; mix them well together; then take a handful from the whole mixture, put it upon a shovel and heat it red hot; then take it from the fire and let it cool; when cold, pulverize it into a fine powder, and pour upon it good cider vinegar; diluted muriatic acid is best, but vinegar, if good, will do; if it foams considerably, you want no lime in the soil; if it does not foam, you must then apply lime. Nearly all the land in the middle States wants lime, and is benefitted by its application. If it wants no lime, then go to work as follows: plow in the fall with the deepest working plow you can afford. In the spring, sow corn broadcast; and as soon as it is as high as you can well turn under with a good plow and two or three horse team, turn it under well, and immediately sow corn again broadcast; as soon as that is high enough to turn under, turn that also with a deep working plow. Generally you may turn under three crops in the same season. In the fall plow deeply in turning the last crop of corn under, harrow and seed with wheat. However poor your land may have been, you may be sure of a good crop of wheat the ensuing harvest. In sowing the corn, about three to four bushels should be sown to the acre, each crop.

If by the trial above described, you find your land requires lime, then, before the first plowing, apply twenty bushels of slaked lime to the acre, broadcast, then plow as before directed, sow the corn, and proceed as before, taking care to sow twenty bushels of lime before turning under each crop of corn; sow the lime on the corn as it stands, and turn corn and lime all in together. In this way, a first rate soil may be made out of the poorest old field in Maryland or any where else; and it will be observed that the only cost is in the liming and value of the seed corn, except the labor. Those who cannot afford to expend so much labor and money the first season, can extend the time over several seasons, applying say twenty or thirty bushels of lime to the acre, and turning under but one crop of corn each year.

The above may be considered a brief summary of the whole argument; and, it seems to me, scarcely requires elucidation. Some may however require explanations, and I therefore proceed to give them.

A clay soil only requires sand to make it a good one, so far as constitution is concerned; a sandy soil requires clay to make *it* good. These two elements of a good soil generally exist on all farms; and wherever they do exist in separate places, they should be combined and mixed, that the whole may be made fertile. If your land be too clayey, and you have no sand on *your* farm, probably some neighbor would be glad to exchange some of his sand for some of your clay, doing half the hauling, and thus both farms will be benefitted at half the labor each. Rely upon it, there is more to be obtained in the improvement of land by a judicious admixture of soils, than is generally supposed. Manuring cannot supply its place, however large the quantity applied; and when once made, the effect is permanent, the benefit perpetual, the improvement lasts *for ever*.

Low wet places are not only unproductive, but they are unhealthy, unseemly, and an absolute loss of all the land so situated. If your farm consists of one hundred acres, and twenty acres of it is of this low and wet kind, you have but eighty acres of land. Therefore drain, by ditching this low land, make it productive, by adding sand, &c., where necessary, and you will in effect have added twenty acres to your farm. And in draining, take care to avail yourself of the advantages of blind ditches. I do not suppose it necessary to tell you how to make them—the way may be found in almost all agricultural works, and they are very simple. A summary of the different plans may be stated as follows: Dig the trench as in the usual way of making an open ditch, of the proper depth and capacity, to carry off the water. Then lay in the bottom of the ditch, stones loosely packed, so that water will freely pass between them, about a foot deep. Then lay upon these loose stones, larger and flat ones, to keep the earth from filling the interstices, and then return the earth thrown out, leveling the whole surface. Some, instead of stone, lay in the bottom of the ditch, branches and limbs of trees and shrubs, and cover these with earth; but such blind ditches are obviously subject to obstruction from the decay of the wood, and thence from the caving in of the superincumbent earth. Others, in Europe especially, use an arching of *tiles* in the ditch instead of stones or brushwood; but this is too expensive for this country as yet. Where stones can be had, a good blind ditch may be made permanently effective by their use; next to stone, brushwood is to be preferred.

It surely cannot be necessary to say a word in illustration of the grubbing up of all useless growths of bushes, trees, &c. Never allow your fences to be sheltered by bushes or trees of any kind; they rot the timber, and you lose all the land they occupy. "Head lands," as they are called, are just so much deducted from your measure of acres. Clear out all such. If you have no other *clean* place in your field, let the head lands and fence corners be clean.

In ascertaining the precise quality of the soil, you accomplish precisely what every other artisan does when he ascertains his ability to do a certain job. You find out what the materials you are to work upon are capable of producing. If in that examination, you find your materials deficient in any one necessary ingredient—lime, for example—you, as other artisans would necessarily and instinctively do, apply lime. If you find it deficient in vegetable fibre, &c., you apply that substance, and if you find it deficient in clay or sand, as either of these preponderate, you apply one or the other, as the result of the examination shall indicate.

Having prepared the soil for the reception of manure, the cheapest and most efficient method and material for supplying nutritious principles to the soil, is the next matter for consideration. I believe that corn sown broadcast, as above directed, is the cheapest, most efficient and speediest fertilizer. Some, and very many, suppose that the old plan of clover laying is the best and cheapest. I differ with them. You can only turn under a crop of clover once in two years; you can by an effort turn under three crops of corn in one year; and I believe that each crop of corn will carry as much nutritious matter into the soil as each crop of clover can do.

Now in this system of improvement, you have only to purchase the lime, if that be necessary; you can raise the seed corn on some part of the farm. All the rest of the improvement is derived from labor.

Never undertake the improvement of more land than you are certain you can manage. If you expend your funds upon too large a surface, you will be likely to lose the whole advantage of them. Calculate how much land you can work *well*, and confine yourself to that and no more. And in all your operations in agriculture, take care not to undertake too much. Suppose you can only work ten acres well in one year, if you undertake twenty acres, some of it will have injustice done to it, and the result is obvious.

Deep plowing is one of the most efficient agents in the improvement of soils, as it is in the continuation of good soils. Never omit it. It may pay you scantily for a year or two; but it will ultimately repay you an hundred fold. Without it there cannot be any continued successful farming, no matter what the original soil may have been. Discard all shallow working plows from your farm, except the mere seed and cultivator plows.

Some lands will be benefitted by fifty bushels of lime to the acre, and by it be rendered sufficiently calcareous; others may require one hundred bushels; all this is to be found out only by proper experiments, as above indicated. If the solution of the soil foams freely in the vinegar or muriatic acid, it wants no lime; if but partially, it wants probably fifty bushels to the acre; if not at all, it may require an hundred bushels. If it be a red clayey soil, it wants more lime than if it be white or blue or yellow.

If you have no lime, and wood ashes are at hand, you may accomplish all the objects you aim at by their application. As ashes are mostly composed of different kinds of lime, besides their more soluble potash, from fifty to one hundred bushels of ashes to the acre, applied in the same manner as directed for lime, will have the same effect as lime, besides giving you the advantage of the potash, the first year.

Where neither lime nor ashes are to be obtained, plaster of Paris, as it is called, may be applied to most lands with advantage. The action of plaster continues to be a subject of dispute. My opinion is, that it simply serves the purpose of fixing the ammonia floating in the atmosphere, and that evolved from decaying animal matters, and thus securing it to the uses of the soil. No matter what its mode of action is, however, it certainly is a very efficient agent in soils generally, and in the absence of other still more effective agents, it should always be used, or at least tried.

I have said nothing of *fencing*, the most expensive item of farming, because it has nothing to do with the main object of this paper, and because the cheapest fence is that at which each locality can afford with the greatest facility. One farmer can build a stone fence all around his farm, easier than he can a rail fence, simply because he has too many stones on his land, and in getting rid of them he hauls them to the line where he intends to make his fence, and in the seasons when he cannot be more profitably employed, he erects the wall. In the absence of stone, and where timber is plenty, the rail fence, the post and rail &c., will of course be the cheapest fencing. I have no favorable opinion of hedges, except in the absolute absence of both stone and timber. They require a long time to grow; and in this country there is not a single

kind of hedge plant that has succeeded satisfactorily. There are a few instances of good hedges being made, but I will venture to say there is not one in the United States that can be imitated profitably as to cost, time and efficiency. If nothing but live fences had ever been in use, and some inventive genius had discovered the use of artificial fencing and stone, he would have been considered the benefactor of his age. For myself, though I have travelled much, and have extended my observations over fifteen of the States of the Union, I have never seen a good efficient hedge occupying the place of ordinary farm fences. And yet the attention of farmers has been directed to it ever since the country was settled; the oldest American writers recommend them; seeds were imported to plant them a century ago; and all these efforts have been continued to the present day with increased force each year. And yet there is not, so far as I know, a single farm in the United States protected by hedges, in all its parts, or in any considerable portion of them. The economical farmer, therefore, will look to some other mode of fencing for protection; and, as said above, that which his land affords most plentifully and most easily of access, is the cheapest and best for him.

I must not omit a few words more upon *deep plowing*. I know it is the general opinion that we must not plow so deep as to turn up the "*hard pan*" of the clay, or the white gravel, &c. &c. I am very certain this is a great popular error. If we had a plow that would turn up the earth two feet deep, I do not care what the subsoil may be, in five years the *fertile soil* would be two feet deep. I admit, that generally a very stinted crop would be produced for the first two or three seasons; but I also assert, that the third or fourth and all subsequent seasons, will pay not only for all the deficiencies of the first two or three, but an hundred fold interest. Wherever a deep working plow has been used, the drouths of a dry season are not felt. The roots of plants pass deeply into the earth, and the burning suns and parching winds pass over them harmlessly. The subsoil plow is a good thing. It enables the farmer to avail himself of most of the advantages of deep plowing without any sacrifice of the first and second season's crop; but then it does not turn up this subsoil—it merely loosens it, enabling the roots to pass deeply. The roots, however, get no other advantage in this deep rooting, than that of protection from drouth; they get no nourishment in those depths. The protection from drouth, however, is an important consideration, and should always be availed of. But I would seek this advantage always when I could by the use of the deep plow, even at the sacrifice of a portion or even all the first two or three crops.

The saving of manure is the next, and though last here, not the least important matter for consideration. Every thing of a vegetable or animal kind, useless for other purposes, on a farm, should be gathered and saved for manure. A convenient compost yard and pit should be provided. The dung from the stables, the weeds from the fields, the chaff and offal straw, cornstalks, &c., the kitchen waters, *contents of chambers*, and all of such things, should be cast into the pit. The pit should be so situated that the drainings of urine, &c., from the stables should pass into it. A shed should be built over it to protect it from rains, and the effects of the sun's rays. Plaster of Paris should be sown over the surface of the manure pit once a week during warm weather, to catch and fix the volatile ammonia that will be continually passing off. If such a thing as a leisure day happen, (which, by the way, I do not see how a *good* farmer can ever have even a leisure moment,) the leaves from the woods may be profitably gathered and thrown into the pit. Twice a year, say in April and October, the contents of the pit should be taken out, thoroughly mixed and piled up to digest for a week or even a month. In forming the piles, if you have any swamp mud or bog earth, you may very properly add two or three loads of this to each load of the contents of the pit, taking care to mix them well. After the pile has stood a sufficient length of time, the compost may be carried out and spread over the land, either as a top dressing, or to be plowed in before seeding.

These are my views of the improvement of worn out and all other land. I submit them with great deference to the farmers of my country. Should they disagree with me in any or all particulars, I trust they will attribute my errors to at least good motives. I desire to do some good in my day, and the agricultural interest is, above all others, most worthy of my efforts, in my opinion. It certainly has my best affections and wishes.

Baltimore, Nov., 1844. GIDEON B. SMITH.

From the Cambridge (Md.) Chronicle.

On the Culture of Indian Corn.

[From a paper read before Dorchester Farmers' Club]

The question of the best method of culture of Indian corn, is one of primary importance; and reports of the various experiments that have resulted favorably, may tend to settle the interesting problem.

The partial practice of my method "by late fall or winter plowing" and "drill planting," for more than fifteen years, and my exclusive adoption of it for half that period, and the obvious reasons in favor of it, have concurred to satisfy me, by the general results, in various kinds of seasons, that it is the best mode of growing that valuable staple of our country—and, at the same time, of sustaining or improving the soil on which it is grown.

I would be understood, in my remarks, to confine them to lands having a due portion of alumina, and at least a moderate coating of grass, or vegetable matters of any kind, on the surface. The method is the following:

During the winter, or late in the fall, the field is plowed under a true and well turned furrow, sufficiently deep to avoid re-turning the sward in the subsequent work; (the accuracy of this operation will have considerable influence on the eventual management and success of the method;) if well done, there will be but little occasion for *hoe* labor, to clear away the grass, as but little will vegetate from the inverted sward.

In this state, the whole will remain till the season for planting, when a light plow is skimmed over the surface in the direction of the first furrow. The "corn planter" is then introduced, which furrows, drops, covers, rakes and rolls the corn, in one operation; or, it may be done, though more tediously, without this instrument.

The lines in which the grains are dropped, are four feet apart; the grain in the lines, about twenty-four inches, and two plants left.

When the corn is sufficiently large, a light double-furrowing, single-horse plow is run as near to the plant as possible, throwing the earth from it, and as soon as convenient, the earth is returned to it. This is the whole of my plowing—then follows the cultivator, as shallow and lightly as possible, to keep the surface at all times friable and open to the free access of sun and air, and not omitting the roller whenever necessary for fine pulverization, which is in all cases essential to good culture. The drier the season, the more the cultivator is used. The hoe is but little required in ordinary seasons for the grass—and never, in any season, to make the slightest hill—and the general cultivation is as *level* as practicable.

By the free admission of the fermentative agents—sun and air—the inverted sward will furnish the soil with the soluble and nutrient gases. The products of its decomposition, which, though volatile, will be fixed by their union with the *moisture, alumina* and other *substances* in the soil; and this process will happen, chiefly, at a time to meet the peculiar demands of the plant, whose organic structure and vital powers will enable it to seize upon, eliminate and apply to its uses the nutriment thus furnished; ammonia and nitric acid, there generated and preserved, will abound in the soil; and in fact, a *quasi* nitre bed is formed among the spongioles of the roots, which will not only yield the gases it may contain, but it will, as is known to every physical inquirer, abstract from the atmosphere, *nitrogen* indefinitely, without which element, a deficit of frequent occurrence, the grain, though it may form and ripen, yet will not contain an essential constituent of food for animal sustenance

By the culture contended for, the porous surface of the inverted turf is presented as a sponge to imbibe readily the ammonia and nitric and carbonic acids, held in solution by the rain and snow which fall upon it, and become fixed as before explained, for the use of the present and future vegetation.

Contrast this with the usual practice of spring and summer plowing, and *cross plowing*; the sward recently turned, is thrown back into its former position; the grass is, as it were, re-planted for much *hoe* labor, as it had not remained in a condition to suffer decomposition; or, so far as it had undergone this process, the products are wasted by exposure on the surface to the action of the sun and air, and a total loss to the plant and soil, or nearly so, is the inevitable consequence.

By *drill* planting too, we may have more than double the number of plants that the usual method allows in safety. Leaving two plants at a point, the distances named, will make about ten thousand stocks to the acre, and the lines arranged in a north and south direction, they will have abundance of space for air and light.

Practically, I have found this to be true. My crops have suffered from drouth less than those under the ordinary practice of cross plowing, which is manifestly to be ascribed to the continual flow of vapours among the roots and their ascent around the plant from the fermenting mass below, promoted by the frequent use of the cultivator, preserving a loose, open surface, and allowing the free entrance of the fermentative agents, heat, air and moisture.

Much more, in *fact* and in theory, might be adduced in favor of the practice indicated, but my paper has already exceeded the limits designed, and I will not now extend the discussion.

Feb. 12, 1845. JOSEPH E. MUSE.

From the Magazine of Horticulture.

On the Cultivation of Lettuce so as to produce successive Crops the year through.

As lettuce is more or less used in every family, the mode of obtaining it in the greatest perfection, throughout the year, in regular succession, may not be unacceptable to a portion of your readers.

Lettuce is grown in considerable quantities for the market, and fine heads may be obtained nearly the winter through; in the months of December and January, owing to our severe weather, it cannot be grown as large as it can in the climate of England, without too much care and expense; but later, when hot beds do not suffer from extreme frost, it may be had in the greatest perfection. Notwithstanding lettuce may be found in the market of such excellence, few individuals, except market gardeners, understand its cultivation during the winter, and on this account many gentlemen are deprived of this desirable vegetable during that season, when it adds so much to the luxury of the table.

The following remarks are the results of several years cultivation of lettuce, both for private use and for the market; and if the directions are carefully followed others may be equally successful.

Selection of Sorts.—There are a few leading points to be strictly adhered to, and which ought not to be overlooked, if lettuce of a superior quality is the object of the cultivator. The tennisball, royal cape, and green curled Silesia, are probably the best for spring use; the imperial (true) is the most worthy of the cultivator's trouble, in order to have a good supply through the summer; and the green cabbage, or hardy hammersmith, for the winter crop. It is of the greatest importance to obtain the seed *true* to the name, and not hybridized; what makes the careful selection of the seed of so much consequence is, that all the care and labor bestowed on the culture of these plants, if raised from spurious seed, approaches very nearly to labor lost. It is well known, although not so universally as could be wished, that a great portion of the varieties enumerated in the catalogues are not worth growing in this climate; the cos lettuce, so much cultivated in England,

and deservedly so, is rarely ever seen in our markets; in fact, all the hybrid varieties, raised from the cos and cabbage lettuces, being intermixed, will not generally be such as would give satisfaction in this country, and more especially if the variety partakes most of the cos parent. Observe therefore to procure choice seed of *responsible* seedsmen.

Compost for the Plants.—A light, rich, friable soil, and old hot-bed manure,—or manure that is as near as can be of the same nature,—well blended together, will ensure success; for framing, the compost should be an equal quantity of manure and earth; this is the secret of obtaining fine lettuce; for wherever fine lettuce is found, extra culture produced it. For open air culture, the ground, however rich it may be in appearance, if not by the recent application of manure, ought to have a bountiful dressing, which should be dug in about three inches below the surface; but before this the ground should have been in fine condition, either by deep plowing or digging; the reason why the manure should not be buried deeper than proposed is, that the roots may take hold of it at once, and that the plants may make a rapid and luxuriant growth.

Sowing the Seed.—To have a regular succession throughout the year, several sowings will be necessary. The first, or spring crop, should be planted from the 15th of February to the 1st of March; the second, or summer crop, during April; and successive sowings in June and August. For the last, or winter crop, the 15th to the 30th of September is the proper period. The seeds generally appear the fourth or fifth day, and the first transplanting should take place ten or twelve days subsequent to their appearance.

Cultivation of the Spring Crop.—Early in February prepare a small hot-bed, unless one is made up for cucumbers, and the seed of the tennisball, or royal cape, may be planted in flower-pots or boxes. It must be borne in mind that only a moderate heat is required for starting the plants from seed. Six inches from the glass is a proper distance for the young plants; give all the light possible through the day, and air every day that the weather will admit of it; the frame must be well secured from frost, which would destroy the plants, and it should be covered every night as long as the cold freezing weather lasts. The plants will require to be twice transplanted—first, from the seed-pots or boxes, about three inches apart, each way, in order to become strong, healthy plants, for their final removal to the beds where they are to remain. This may appear to those persons not already acquainted with the process, to be superfluous; however, it is the only way to succeed. The final transplanting out into frames should take place as soon as the plants are ready,—if the tennisball and royal cape, or Silesia, about nine inches apart, each way, will be found to be a proper distance. Regular attendance to the watering, giving air every favorable opportunity, and covering over the frames every night in season, is all that is necessary to ensure fine early lettuce.

Cultivation in the open air.—Early in April seeds of the tennisball should be again sown, and the plants will be ready by the middle of May to transplant. It will be necessary at this season to allow about fifteen inches between the rows, in order to admit the Dutch hoe, or scuffle, to advantage, which should be frequently used. The imperial should succeed the crop of tennisball and Silesia, and the first of May the plants will be in readiness. Continue to plant as before advised, every month or six weeks, from early spring to autumn, and select a cool situation for the late summer crops.

Cultivation of the Winter Crop.—This is the sowing requiring the most attention, and which is to supply the table from January to March. Select a warm situation in the open ground, and manure the bed well, and dig it deep; make the surface level and smooth with a fine rake, and it is then ready for the seed. The hardy hammersmith is the variety to sow now; draw the drills three inches apart, and cover the seeds lightly. In a few days they will be up and grow rapidly—and in October they should be transplanted into beds, where they are to be protected from frost. These should be common hot-bed frames; and as soon as the nights become cool, the sashes should be put on, removing them early every fair day. On the approach of severe cold, secure the plants from the effects of frost in season, for freezing and thawing would nearly destroy the whole. Very little water will be needed, unless there should be a continuance of fine weather, till Christmas, when they will require moderate waterings. Give all the light and air possible, and keep the plants clean and free from damp, by picking off all decayed leaves as soon as perceived.

In December the plants will be very strong and stocky, and ready for removal to hot-beds, or pits in the green-house; where, with the ordinary treatment, they will soon form fine large heads. From time to time, as a succession is wanted, the plants can be transplanted from frames to heat, until the season arrives for the spring crop.

Necessity of Rotation.

In one of the lectures of Prof. Johnston we find the above named doctrine made so plain that any body can understand it. We commend it to all who suppose that because their lands do not give out in two or three years, they never will.

"The following table shows the quantity of inorganic matter in 100 lbs. of hay:—

	In rye grass hay.	*Red clover.*	*White do.*	*Lucerne.*
Potash,	8.8	19.9	31.0	13.4
Soda,	3.9	5.3	5.8	6.2
Lime,	7.3	27.8	23.5	48.3
Alumina,	0.3	0.2	1.9	0.3
Oxide of Iron,	0.0	0.0	0.6	0.3
Oxide of Manganese,	0.0	0.0	0.0	0.0
Silica	27.7	3.6	14.7	3.3
Sulphuric Acid,	3.5	4.5	3.5	4.0
Phosphoric Acid	0.3	6.6	5.0	13.1
Carbonic Acid	0.1	3.6	2.1	3.2

The soil must contain all of the above, otherwise it cannot build up the plant which contains them; and just in proportion to the supply of the necessary ingredients, in their proper proportions, will be the luxuriance or stuntedness of the crop. Every plant that grows requires, in accordance with the nature and composition of soil, the proportion of the ingredients in its ashes. If no alternation of crops is made, nature will become exhausted in some of her resources, and the plant, for want of nourishment, must die. We have facts to prove that nature will not for ever grow the same plant on the same soil. The Black Forest consisted first of oak, then of pine, and now it is again covered with broad-leaved trees; and as with trees, so with crops—and as on a large, so on a small scale. Different modes of husbandry have been adopted. Instead of oats being grown fifteen or twenty years on the same soil, the rotation of three white crops and six years' grass was adopted; this also has become antiquated, and now the preferable alternation of white and green crops is adopted. Alternating crops, and adding such manures as have been carried off by preceding crops, is the only profitable mode of cultivation, while nature will also assist by the going on of certain circumstances, such as the decomposition of minerals, &c. A soil containing just sufficient lime for a luxuriant crop of rye-grass, would be far deficient for either clover or lucerne. The soil must contain in abundance what your crop specially requires, and consequently the necessity of selecting the manure to suit the crop wanted; and skilful farmers will put this principle into practice, and also select crops suitable for the purpose to which they are to be applied; thus, if you wish to feed for milk you must select a plant containing an abundant supply of phosphoric acid; and this plant will not grow on land which has been exhausted of this acid, though it contain all other necessary ingredients in abundance. The ground becomes exhausted in many ways. By cropping too long with either one kind or different kinds of grain, and carrying off both grain and straw, it becomes exhausted very speedily. It becomes exhausted of some of its soluble matter by the action of rains, just in proportion to the wetness of the soil. By the application of proper manures, the waste may be replaced. Feeding will replace a portion of the waste of solid matter; but a great portion of the soluble is lost, both by being, to a small extent, irrecoverable, and because of the direct waste by carelessness or ignorance. These soluble or saline substances are principally contained in the urine of cattle, and just in proportion as it is lost, so is the direct waste. The urine of one single cow is valued in Flanders at £2 per annum. What, then, must be the loss on the whole of the cows in Great Britain? Guano is not a more valuable manure than the urine of cattle; and yet farmers carry off this from their yards by large ditches, as if it were only, what it has been too long considered, a nuisance, while they will give £10 a ton for an article of no greater value. By building suitable tanks, the whole of the farm-yard saline matter might be preserved, and 900 lbs. of good solid matter, equal to the best Peruvian guano, would be the annual produce of one cow. Tanks ought to be made capable of containing all the urine voided in four months; they should be divided in the middle, and one end when filled, should be allowed to ferment. This fermentation would be completed in about six weeks, when it should be carried to the land and applied as we now apply guano and water. In the process of fermentation, the ammonia is apt to escape; but by mixing the urine with three times its bulk of water, this will be prevented to a very considerable extent, as shown in the following table:

Saline Matter and Ammonia in the Urine voided by a Cow in twelve months.

	lbs.		lbs.
Recent urine contains— solid matter,	900	Yields of ammonia,	226
Kept 6 weeks—mixed with water,	850	" "	200
Kept 6 weeks, unmixed,	550	" "	30

"We have frequently been astonished at the results of certain saline substances when scattered over unhealthy plants, by the first shower washed into the soil, and immediately consumed by the plant as its proper and necessary food; and just in proportion to the ease with which it gets the substances upon which it is supported, and of which it is composed, will it vegetate. Suppose any of the substances of which a plant is composed to be already in the ground in sufficient proportion, then any addition cannot do good. Suppose soda to be in sufficient quantity for hay, any addition would be unprofitable for a rye-grass crop, while it would be of immense benefit to double the quantity for clover or lucerne. And again, some soils contain it in sufficient quantity for every variety of crop, consequently any addition would be unprofitable.—Hence the reason of so many conflicting opinions respecting the utility of manures. A. B. has a field deficient in the due proportion of gypsum; and, by applying it to his crop, he finds the most beneficial effects. C. D. hears of these results, and applies it to his fields, which have already an abundant quantity of it, but require something else; and the consequence is, it does no good, and he pronounces it worthless as a manure; and his next neighbor, E. F., who would have been benefitted by its application, has been dissuaded from applying it. Milk contains so much bony earth that in seventy-five years a cow pastured on an acre of land will carry off a ton of bone; hence some lands used for dairy purposes in Cheshire had, in the course of years, deteriorated to such a degree that they were not worth more than from 5s. to 10s. per acre, just because the cows pastured on them had carried away all the bone out of the soil. Bone dust was at length applied as a top dressing, and the results were so astonishing that the land increased 700 per cent. in value, and the rector's tithes were increased five fold. Any or all other manures, had they wanted bone, would have proved ineffectual. The bones added just what had gradually been taken off in the lapse of years, in consequence of the peculiar husbandry of the district.

From the Southern Shield.

Barbour County Agricultural Society.

A meeting of the Barbour County Agricultural Society was held this day in the academy in this place. The President, Col. John L. Hunter, in the Chair, and, in the absence of the Secretary, Benj. Gardner was requested to act as Secretary.

Col. Hunter, the chairman of the committee appointed at the last meeting, to prepare an Address to the President of the State Agricultural Society, on the importance of adopting some active measures for the promotion of the interest of the cotton growing section, submitted the following:—

To the Hon. HENRY W. COLLIER, President of the State Agricultural Society of Alabama:

SIR:—In obedience to a resolution of the Barbour County Agricultural Society, the undersigned have the honor to address you on the present condition and future prospects of the cotton planters, and through you, as an honorable medium, to communicate to them their views and sentiments on those interesting and important subjects.

The cotton market, on which depends the prosperity of our southern country, threatens distress and ruin; but a small further reduction in the price of our southern staple, and our community will be driven to seek another culture, or have the mortification to behold their lands and negroes valueless and an expense on their hands.

It is true that the abandonment of the cotton culture, would eventuate finally in advancing the price, but in the interim the planter must endure heavy losses and great suffering. The time has passed away, when our people were buoyant with the hopes of the sudden accumulation of wealth, the mania for speculation in lands as well as in negroes has departed, leaving us to serious and sober reflection, and we trust under Divine Providence, with future lessons of experience and wisdom for our further guidance, benefit and happiness. God in his wisdom afflicts mankind, but in his mercy points them to a remedy. The causes of our distressed condition are few, obvious and striking. * * * * * *

The chief and greatest source of the evil lies not in legislation, but in a law of trade that cannot be regulated by it. Every planter must know that supply and demand will regulate the price of cotton; and while our planters continue to raise hundreds of thousands of bales over and above the wants of the manufacturers and their customers, the price must continue to decline until a ruinous business drives him from his folly of overproduction. The consumption for our cotton has increased, and will continue to increase, but the production outstrips it.

A small crop would command as much, if not more, by the augmentation of the price, than a large one; besides he saves the expense (no small item) of extra bagging and rope, and is able to devote his labor to a larger provision crop—to the improvement of his land and stock and to other additional cultures more profitable than cotton where the climate is favorable, to wit: wheat, hemp, rice, sugar and tobacco.

The cotton planter has been stimulated by the former high prices he obtained for his cotton until he has become so infatuated with the cotton culture, as to direct all his energies and resources to it at the expense of every other interest to the almost entire neglect of his means of comfort and independence on his plantation.

Fortunately it is within his power to correct this evil; to arrest the downward tendency of the cotton market, and to avert the impending ruin. Independent of the consideration of advancing the price of cotton it is his true policy to cultivate a large provision crop that he may have an abundance in a bad season and to spare, and a greater abundance in a good one. He should calculate to have provisions to sell to those classes who do not cultivate the earth, and in this way, to pay all the incidental expenses of his plantation. He will then have no more cotton in cultivation than he can comfortably and neatly harvest by the 24th day of December; and in the months of January and February, generally cold and inclement and unfit for cotton picking, he can more advantageously turn his attention and devote his labor to necessary repairs, to the improvement of his soil—to the improvement of his stock—or, in other words, to go more upon farming, and deal more mercifully with his lands, his laborers and stock, and to receive from them a grateful return, to make him comfortable and independent on his plantation, as he ought to be.

It is his policy to encourage the manufacture of cotton by using and consuming in his dress and in his household whatever articles can be made of cotton. In the cotton region, it should be the pride of our ladies, who are always foremost in every good word and work, to prohibit by their use, precept and example, the use of any article not made of cotton, where the cotton fabric can be made to answer their purpose—the silks should give way to the fine chintzes, muslins and calicoes, so well calculated to add to their personal comfort and beauty. It has been stated in a late periodical that cotton applied to the use of matresses, comforts and blankets for the consumption of the southern States, containing five millions of population, would amount to more than 200,000 bales.

Another still larger source of consumption would be found in using cotton cotton-bagging for wrappers for our bales. We do not know that cotton is more impervious to water than hemp and it would be well to give it a fair trial.

Our State Legislatures should not be backward in such times as these to develope the resources of their respective States and call forth their energies and direct their citizens to an advantageous division of labor from the culture of cotton.

Alabama abounds in some districts in coal mines and marble quarries, which might furnish a large portion of laborers now in the culture of cotton, with more profitable employment.

In conclusion we beg leave to recommend a convention of the cotton planters of the southern States, to be held at some central situation at as early a day as practicable, to devise and concert measures for their own safety and relief, and we would rely on their intelligence, good sense and honesty, in carrying out the decisions of that convention. Should a large portion of our planters, however, persist in their folly, notwithstanding the admonitions of their experience, and the action of the convention, to plant a large cotton crop, the market will continue to decline, and render the culture unprofitable and expensive; but such planters will stand in no enviable position in point of interest, and will reap the harvest due their folly. We would most respectfully solicit your co-operation and action in accomplishing the objects so desirable which have called forth this communication.

We have the honor to be, with profound respect, your obd't. serv'ts.,

JOHN L. HUNTER,
J. A. CALHOUN,
R. C. SHORTER,
} *Committee.*

Col. McDonald, from the committee appointed to address the planters of Barbour County upon the propriety and necessity of greatly reducing their cotton crop, presented the following:

To the President of the Barbour County Agricultural Society:

SIR:—Having been appointed a committee to address the farmers of Barbour County on the present state of the cotton market, we enter on the duty assigned us with a knowledge of the difficulty of persuading the cultivators of the soil to change their system.

From the extreme low price of the great southern staple, at the present time, it is obvious that a change must take place, and the sooner it is commenced the better. When we look abroad, over the world, we see an increased accumulation of cotton to an extent heretofore unknown. It appears, from the latest accounts from Liverpool, that the stock on hand amounted to 750,000 bales, which was an increase on the stock at the corresponding period in 1844, of 100,000 bales, and the price, a penny lower than it was at the same time last year. Large stocks, in Europe and in this country, indicate low prices, for sometime to come: for when the immense crop of 1844 reaches England, there will, in all probability, be an increase on the present stock, of 100,000 bales, and a corresponding reduction on the price. An inquiry naturally arises, what is to be done? The answer is at hand. Let us greatly reduce our cotton crops, which will enable us to prepare for market a better article—it will also enable us to improve our farms and thereby promote our happiness and comfort. Let us, at the same time, greatly increase our provision crops, making a large supply of provisions of every kind. We would also recommend that a portion of the labor now employed in the cultivation and preparation of cotton, be turned into other channels—the raising of rice and tobacco, as well as the growing of wool. We believe that these would be much more profitable than cotton at the present prices.

Thus, fellow-citizens, have we thrown togegether, a few hasty thoughts for your consideration.

A. McDONALD.
J. G. SHORTER.
J. BUFORD.

Col. McDonald, also, made the following report in relation to some seeds, which had been forwarded to the Society:

To the President of the Agricultural Society:

SIR:—On the 19th of last March, I received, by the kindness of Mr. Woods, from the Hon. H. L. Elsworth, the following seeds, which were sent to the Society by the Hon. Mr. Belser, viz: The bassana beet, the multicauli rye, from France, the white flint wheat, the calico corn, the Calcutta flax seed, the pole bean, the twin corn, the multicauli rye, of the United States, and the white prolific bunch bean. I immediately turned over the seeds to the President of the Society, keeping a few of each kind to sow and plant. On the 27th of March, I planted and sowed them in my garden, having some fears, however, that the rye and wheat might not mature, sowed at that season of the year, but fearing that they would be destroyed by the weavel, I thought it best to risk it. All the seeds came up except the beet, and on the 24th of June, when I left home, they all promised well, but on my return on the 20th of September, the gardener stated that the rye and wheat did not come to maturity. I only planted two grains of the calico corn, it too, was entirely destroyed by the weavel. I have saved some of the twin corn, the prolific bunch bean, a few of the flax seed, and a few of the pole bean, which I now present to the Society. A. McDONALD.

Mr. G. W. Pournell became a member of the Society, and expressed a desire that the interest of the mechanic would hereafter receive some consideration. Being a blacksmith, he called attention to some specimen plows of his own manufacture, which he had brought for the inspection of the meeting. They were much admired by the planters present, being considered fully as good as those brought from a distance, if not something better.

Mr. Cargile also directed the attention of the meeting to some brogans of his own manufacture, which were stout, strong and well made.

The Society then proceeded to the election of its officers for the current year, which resulted as follows:

ALEX. McDONALD, President.
J. M. RAIFORD, 1st Vice President.
WM. DEWITT, 2d do.
T. FLOURNOY, Treasurer.
A McGEHEE, Recording Secretary.
B. GARDNER, Corresponding do.

Executive Committee.

WM. S. PAULLIN. J. G. SHORTER.
J. BUFORD. WM. ABNEY.
T. CARGILE.

Col. McDonald then took the Chair, and returned his thanks to the Society for the honor conferred in electing him President, and earnestly solicited all to lend their energies to promote the objects for which the Society was organized. Unless this was done—unless every man went to work as if he felt there was something to be done, and something for *him* to do, he thought it better that we quit the house and never enter it again in the capacity of an agricultural society. He alluded to the praiseworthy examples of the Farmers' Club of Hancock County, Ga., and other associations of a similar character, and then exhorted the members to a similar course on their part. He concluded by suggesting that another meeting of the Society be held on the third Saturday in March, at which time it would be advisable to adopt the necessary measures for holding an Agricultural Fair in this place some time during the fall, at the same time leading the way with a contribution for that purpose—remarking, that if we expected to do any thing, we must have money, without it, we could do nothing. This example was immediately followed by other gentlemen present.

On motion, Messrs. McDonald, Buford and J. G. Shorter were appointed to revise the Constitution.

On motion, the Society adjourned until Saturday the 15th of March, to meet in the Hall of the Market house. A. McDonald, Pres't.

B. Gardner, Sec'ty. pro tem.

Eufaula, Ala, Feb. 22, 1845.

From the Boston Cultivator.

Agricultural Chemistry.

Messrs. Editors:—Not long since, I heard a person who possessed some knowledge of agricultural chemistry, telling some farmers and others, that a large part of the solid substance of trees, and other vegetable productions, was derived from the air, or rather, that part of the atmosphere called carbonic acid, and that this acid, or gas, was precisely like that which issues from a barrel of fermenting beer or cider. After the man left them, they began to express their doubts about the truth of his theory. Says one, 'tis all nonsense, the visionary dreamings of a book farmer. Yes, says another, if his doctrine is true, what's the use of manure, muck, and composts that he talks so much about. A third one observes, when he can make me believe that the moon is made of green cheese, I shall believe his story about trees being made out of the steam that flies out of the bung-hole of a barrel, when the cider is *working*.

Now, Messrs. Editors, I cannot think any of your readers are so ignorant, but still some of them may not have taken pains to investigate the subject as they ought, either from a belief that it is not necessary for a "common farmer," or that chemistry is too intricate a study for the tiller of the soil to trouble his head about.

To while away an evening, and, perhaps, to throw a little light upon the subject, I forward you the following, with the hope it may in some measure stimulate farmers to a more familiar study of agricultural chemistry. Of its importance there can no longer be any doubt; it is a matter about which there "are no two ways."

The atmosphere we breathe and in which plants grow and live, is compounded principally of a mixture of oxygen and nitrogen gases, in the proportion very nearly of 21 of the former to 79 of the latter. It also contains as a constituent necessary to the very existence of vegetable life, a small per centage of carbonic acid, on an average of about 1.2599 part. At first view it would seem impossible that this apparently small amount of carbonic acid could supply about one-half the solid substance to all plants that annually grow upon the whole face of the globe—but when we recollect that the atmosphere not only entirely surrounds the earth, but extends in every direction about 45 miles—"and if the whole acid were collected in a stratum or bed occupying the lower part of the atmosphere, such a stratum would have a thickness of about thirteen feet;" and this would be spread over the entire waters of the oceans, seas, lakes and rivers, the deserts of sand, the frozen regions of the poles, and in fact over every part and place of the globe that does not yield a vegetable growth, and by the wisdom of the greatest Contriver, this gas is, in innumerable ways, returned to the air as fast as abstracted; here then our wonder ceases. Now, from 40 to 50 per cent. by right, of all trees, plants and vegetables, and in fact all parts of plants which are cultivated for the food of animals, or of man, consists of carbon, and unquestionably most of this is derived from the air—although there can be no doubt that a small portion is taken in by the roots, mixed with water, and some of the inorganic substances that are in solution—but this was also derived from the air.

The leaves of plants are their lungs, and they have the powers of taking in or absorbing from the air the carbonic acid, and in daylight this gas is decomposed, but much more rapid and energetic in clear sunlight. This gas is composed of two proportions of oxygen and one of carbon, and when decomposed in the leaf, the oxygen is set free and escapes into the air—the carbon is retained, and in obedience to those mysterious laws of chemical combinations, is made to form a moiety of the endless variety of wood, fruit, seeds, &c. &c., that grow upon the earth.

In proof of this, I will offer the following illustration. We know, if we take a given quantity (by weight) of well seasoned wood and distil it in a close vessel, or burn it in heaps covered over so as to exclude the free access of air, wood-charcoal is left behind. When this process is well performed, the charcoal will weigh from 40 to 50 per cent as much as the wood did. The charcoal consists of carbon, with a slight admixture only of earthy and saline matter, which remains behind when the coal or carbon is burned in the open air. When this charcoal (or carbon) is burned in the open air, it combines with the oxygen (which is separated from the nitrogen) of the air to keep up combustion, and the whole of the coal enters into combination with the oxygen and forms carbonic acid—or, in other words, carbonic acid consists of oxygen with a quantity of charcoal *dissolved* in it, and this is precisely the gas that escapes from a barrel of fermenting beer or cider, and in this condition it is *fitted* to be again taken in by the leaves of plants and reconverted into wood, fruit, seeds, &c. &c., and this process has been going on without intermission from the first morn of time down to the present day.

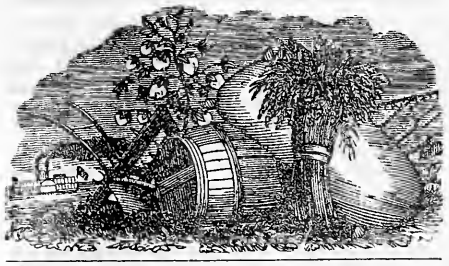
Perhaps it may seem somewhat mysterious to many or all, how this elastic invisible gas can be converted into wood or other solid substances, but it is no more wonderful than many other of its combinations. Every 100 lbs. of pure marble or limestone, as taken from the quarry, contains in round numbers 44 lbs. of this very gas; by subjecting the marble to a strong red heat, this gas is driven off, and leaves but 56 lbs. of lime. In this town there is a pearl-ash factory. In every 100 lbs. of pearl-ash the manufacturer sends to Boston, there is 32 lbs. of this gas combined with 68 lbs. of caustic pearl-ash, or to place it in another point of view, in sending 70 lbs. of pearl-ash, 22 lbs. of it is carbonic acid. The pearl-ash is taken to the distillery, and a current of carbonic acid is made to pass through it, when another portion of the acid is made to combine, and the 70 lbs. of pearl-ash come out 92 lbs. of salæratus,—that is, 22 lbs. more of this gas is fixed in the pearl-ash. At the distilleries this gas is disengaged from the molasses and water while fermenting, preparatory to its being distilled into spirit. Now can any one tell how this 44 lbs. of gas got combined with 66 lbs. of lime, so as to form 100 lbs. of marble? or how 44 lbs. of carbonic acid entered into combination with 48 lbs. of caustic potash to make 92 of salæratus? If a pound of charcoal is burned in a close vessel of oxygen gas sufficient to keep up combustion till the whole of the coal is consumed, there is neither gain nor loss in the weight, the pound of charcoal is *dissolved* in the oxygen, and the gas weighs a pound more than it did before combustion commenced, and what is still more strange, the volume or bulk of the gas is not increased by the addition of the pound of charcoal or carbon. The quality or nature of the gas is materially changed—being converted into carbonic acid. Perhaps no one can tell, or perfectly understand the "modus operandi" of the above, but of the truth of the statements we are as confident as we are that two and two make four. It is well known that lichens and mosses will grow and thrive upon the solid rocks. Aaron's rod and some other plants will flourish and gain in weight suspended in the air. The roots of a hyacinth, when the bulb is placed over a glass vase of water, will descend into it, the leaves and flowery stem will shoot upwards, and fragrant flowers are produced; during this time the water is not changed nor any manure added, and perhaps the whole plant when in bloom will weigh twice as much as it did when placed in the vase. Now from what source do these plants draw their growth but from the air? But some may say this is on too small a scale to satisfy them; then we will take it upon a larger one. We know, if we take crop after crop from a given piece of land, without returning any thing in the form of manure, it is yearly impoverished till at last it will scarcely produce any thing. The reason of this is, we carry from the land all that is derived from the air, and all that is drawn from the soil, *the inorganic parts of plants*, which are just as necessary as the carbon; the soil thus becomes destitute of it—part of the funds necessary to carry on the co-partnership—but the air is always solvent, ready to meet its engagements at sight, and contribute its full quota in proportion with the other part of the joint concern, and no farther. But if this impoverished soil is sown with the seeds of some kinds of trees, and they vegetate and grow, the longer they stand and the larger they grow, the richer and more fertile the soil becomes. If this growth of trees had derived its whole food from the soil, it would have been poorer than when it was planted; but as that is not the fact, we can come to no other conclusion than that the *food* for the carbon of the trees was drawn from the carbonic acid of the air, and the other organic substances from the air, water and the soil.

The inorganic matters that enter into the composition of the plants, silex, lime, potash, soda, gypsum, &c., drawn wholly from the soil, are gradually supplied by the mineral constituents of the soil, which generally yield them as fast as required for the growth of forest trees, without the aid or application of them by the hand of man. But not so with our cultivated crops, they are annually carried from the land, and to keep up the fertility of the soil, the inorganic matter must be returned in a more soluble form than they exist in the mineral constituents of crops which do not decompose fast enough to supply annual crops of corn and grain for a very long series of years.—Please excuse the length, and repetitions in this; my object is to be understood by that class who are not familiar with "agricultural chemistry."

Yours, truly, Levi Bartlett.

Warner, N. H., Dec. 24, 1844.

Gulf Stream.—It may not be generally conceded that Dr. Franklin first made known to the world the existence of the Gulf stream. It was made known to him by a Nantucket whaler, while in London, in 1770. The stream had been previously ignorantly crossed, by European sailors, for nearly three hundred years before this. Franklin received from the sailor, whose name we do not recollect, a map of this current, and in 1775 discovered the higher temperature of its waters. The publication caused the trade of the Northern ports to increase rapidly in consequence of the advantages in the winter to be derived from it in the management of vessels



The Southern Cultivator.

AUGUSTA, GA.

TUESDAY, APRIL 1, 1845.

A PREMIUM.

The Publishers of the "SOUTHERN CULTIVATOR," propose to give to every man who shall procure TEN subscribers, and enclose a ten dollar bill, the two back Volumes of the work, handsomely bound.

☞ Subscribers to the present volume of the CULTIVATOR, can be supplied with the back numbers. We can also furnish the two back VOLUMES complete, at the subscription price.

☞ The package of seeds sent to the editor of the Cultivator, has been received, and distributed.

Premiums Awarded.

In our Prospectus of the third volume of the "SOUTHERN CULTIVATOR," we offered six Premiums, to those who should interest themselves in obtaining subscribers—to be awarded on the 1st of March—and we have now the pleasure of announcing the result.

To the Hon. CHARLES DOUGHERTY, of Athens, Ga., was awarded the first premium—"*A Silver Goblet*, with appropriate Agricultural designs and inscription, worth $25," for obtaining over ONE HUNDRED subscribers.

To Col. ALEXANDER McDONALD, of Eufaula, Barbour Co., Ala., the third—"A similar Goblet, worth $15," for obtaining over SIXTY-FIVE subscribers.

To GREEN B. HAYGOOD, Esq., of Watkinsville, Ga., the fourth—"Loudon's Encyclopædia of Agriculture, worth $10," for obtaining over FIFTY subscribers.

To CHARLES HUTCHINGS, Esq., of Clinton, Ga., the fifth—"Johnson's Encyclopædia and Dictionary of Rural Affairs, worth $5," for obtaining over FORTY subscribers.

It will thus be seen that no one has obtained either the second or sixth premium, both of which we should have been much pleased to have awarded to some of our Agricultural friends in testimony of their zeal in the cause.

In announcing the result we cannot permit the occasion to pass, without tendering to each of the above named gentlemen our most cordial thanks for the interest taken by them in our enterprise, and to express our gratitude for their efforts in stimulating others to increased exertion, in behalf of the work. Nor would we omit to tender our sincere acknowledgements to all others, although less successful, who have exerted any influence to obtain subscribers to the work.

The premiums will be ready for delivery at an early day, of which we will advise the respective recipients, and receive their respective orders in reference to them.

Postage.

The thoughtlessness of some of our friends frequently subjects the publishers to the payment of postage, which is as unjust as it is burthensome. For instance, some one wishes the direction of his paper changed from one Post Office to another, and forthwith writes us a letter, which he forwards *without paying the postage*, and we are accordingly subjected to this tax on business purely his. Again: some friend wants to become a subscriber, and encloses the money in a letter, POSTAGE NOT PAID, and we are consequently taxed double postage.

It is true that the postage on a letter is of very little consequence so far as the amount is concerned, but when our friends reflect that the price of subscription to our paper is only *One Dollar*, a moment's reflection will satisfy them that we cannot afford to pay the postage on letters pertaining exclusively to the business of the writers.

Besides, it is an easy matter to avoid thus taxing us, by simply requesting the Post Master to enclose the money, or request the change in the direction of a paper, all of which he is authorized to do.

Agricultural Education.

Much as book-farming has been ridiculed and despised in times past, and much as it is held in contempt in parts of the South even now, still the day is fast approaching when those who have thus acted will rue their folly. Even though we may incur the risk of being laughed at, yet we will take the liberty of saying that, day by day, the value of mere bone and muscle, as a mechanical agent, is becoming less and less, and ere long mere bones and muscles will become worthless as to any profitable use that can be made of them, unless their operations shall be guided by the light of this very book-learning so much despised. One reason why the South is so far behind the other sections of the Union is, because we have not long ago understood and appreciated this important truth about the decreasing value of mere bone and muscle. In New York, for example, all this was comprehended long ago, and as a consequence, their Agricultural Institute is a regular college for teaching a system of Agriculture, suited to that soil and climate. There, the student learns all the facts in Chemistry, Geology, and Botany, so far as they are immediately useful in Agriculture. He is taught how to prepare and drain soils; how to collect, store away, and preserve provender, grain, fruit, &c.; how to feed, and take care of, and improve stock; how to take care of orchards, vineyards, gardens, &c.; how to prepare and apply manures to the best advantage; and, indeed every thing that is necessary to make a man accomplished in both the practice and the science of Agriculture.

Even in the adjoining State of Tennessee, they are ahead of us in this matter of Agricultural Education. On the first of January last, an Agricultural College was opened in that State, with between forty and fifty students; and our latest information about it is, that the number will very soon be as large as can be accommodated. We have now before us a catalogue of the students, including young men from the States of Tennessee, Alabama, Mississippi, Missouri and Kentucky: not one from Georgia.

In this connection we copy from the Globe newspaper, an article showing what the National Agricultural Society is doing, and proposes to do, for Agricultural Education. Let the reader con it over carefully, and very seriously, and then ask himself if it be not his duty to bestir himself and do something for Agricultural Education in the South—in Georgia especially—so that the light of science may be brought to the aid and direction of the bone and muscle of this section of the country, ere the advances made elsewhere shall make his efforts vain and profitless.

How is this to be done? you ask. Very easily indeed. The tillers of the ground are a part of the State so numerous and important that, without them, the State could not exist. They have only, therefore, to have a proper notion of their own importance, and to assert their rights as men ought: to demand that in our system of education, so far as it is supported by the State, due regard shall be paid to the interests of their profession, and that the funds of the State shall not be applied almost exclusively, as heretofore, to the preparation of young men for the study of the learned professions, so called—two of which at least, if not already, will soon be, at the present rate of increase, filled up to starvation point. The planters pay by far the larger part of the public taxes; and they ought to see that these taxes are expended in like proportion for their benefit. In a word, they should demand that the system of education in the State University shall include a Professorship of Agricultural Chemistry and Geology—and demanding this as their right, they should see that their agents in the Legislature provide the means of sustaining such professorship.

AGRICULTURAL EDUCATION.

The National Agricultural Society has lately adopted a plan that promises valuable results in promoting improvement among the farming community in all quarters of the Union. That plan is briefly set forth in the annexed proceedings, and has the merit of involving little expense, while largely stimulating attention to the great purposes for which the National Society was founded. The proceedings, as communicated to a late Agricultural Convention in the State of New York, and published in the Albany Argus, were as follows: Globe.

"NATIONAL AGRICULTURAL SOCIETY.—At a meeting of the members of the National Agricultural Society, at the City of Washington, on the 10th of January, 1845, Mr. Ellsworth, Commissioner of the Patent Office, in the chair, and Mr. Callan, Secretary,—inquiry turned upon the means whereby the efforts of the friends of agricultural improvement may be made more united and efficient throughout the United States. The matter which most particularly arrested attention was the report of the operations for 'extending agricultural knowledge, through the instrumentality of the common-school organization of the State of New York.' The report on this subject is in pamphlet form, and emanated from a committee of which the Hon. John Greig, late member of Congress, is

chairman, and of which James S. Wadsworth, of Western New York, late president of the State Agricultural Society, and the Hon. Daniel S. Dickinson, now senator from that State, are among the members. The report includes letters from various persons in different States, as well as from many parts of that State, approving warmly of the plan pursued by the committee for promoting the introduction of agricultural books in the schools and libraries of that State. The value of this movement may be estimated from the fact that there are about twelve thousand school and library districts, with superintendents of schools in every town and county of that great State.

"Allusion was made to the *cheapness* as well as *efficiency* of this plan of action; inasmuch as it accomplishes its object by bringing the whole common school organization to aid the cause of agriculture and horticulture; at the same time that the general interest of the school must be largely benefited by the increased practical value imparted to education through this connection with what is appropriately termed 'the staple business of society—the culture of the earth.'

"After mature consideration, it was determined that the National Agricultural Society approve and adopt the plan set forth by the New York State Agricultural Society, as a plan that is applicable wherever schools or colleges exist, and which can be prosecuted cheaply and efficiently, especially in States where school organizations are judiciously arranged.

"With the view of promoting the extension of this plan throughout the United States, additional corresponding secretaries were appointed as follows: T. S. Pleasants, of Virginia; Henry O'Reily, of New York; Thomas Affleck, of Mississippi; Oliver Comstock, of Michigan; A. G. Summer, of Columbia, S. C.; and Henry Barnard, of Connecticut.

"It is recommended to the newly appointed secretaries to correspond freely with each other and particularly with the officers of the society at Washington, as well as with the friends of agricultural education generally in all sections of the Union, so as to produce the greatest efficiency by co-operation in the cause.

"A resolution was adopted directing these proceedings to be published in the agricultural and other journals; and another resolution required that copies thereof be forwarded to the several State Agricultural Societies in the Union. J. S. SKINNER, Cor. Sec.

"*Post Office Department, Jan.* 10, 1845."

Bermuda Grass.

The Macon Telegraph, in a notice of the CULTIVATOR, (for which it has our thanks,) speaks thus on the subject of Bermuda Grass:

"A communication on the subject of Bermuda Grass, we transfer to our columns from those of the Cultivator; and while we appreciate the value of that grass for grazing, we would ask the editor of the Cultivator at a leisure time to inform us as to the most practicable plan of getting clear of Bermuda Grass when the land is wanted for other purposes. Our farmers generally deprecate its taking root on a corner of their plantations, as they would a great calamity. Its spread is slow when undisturbed by the plough, but sure and steady; and we have never yet learned how it is to be entirely eradicated from a field on which it has hold.

"If this paramount objection can be remedied and it can be destroyed at pleasure, we believe no grass, or scarcely any grain, would be more useful to the South."

No one, neither Mr. Spalding nor Mr. Affleck, can have a higher opinion than we have of the very great value of this grass both for hay and pasture; and we are, at the same time, fully aware of the extreme dislike with which it is regarded by our planters. It would seem to be contrary to nature that what is of so much value should, at the same time, be so great a pest.—There must, therefore, be a mode by which it can be subdued. We beg leave to call the attention of Mr. Spalding and Mr. Affleck to this point, with the hope that they will furnish us with the result of their experience. If they will do this, and shall propose a plan by which Bermuda Grass may be effectually rooted out, whenever it is desired to use the land it occupies for other purposes, they will confer a favor on the planters of the South that will not soon be forgotten.

In Elliott's Botany we find a notice of the Bermuda Grass, which goes to confirm all our impressions as to its great value. He says:—"We have two varieties of this plant, one coarser, (perhaps a species,) growing in damp soils, and native; the other, said to be imported, a tender, delicate grass, growing over and binding the most arid and loose lands in our country, *and apparently preferred by stock of all descriptions to every other grass.* The cultivation of this grass on the poor and extensive sand hills of our middle country, would probably convert them into sheep-walks of great value; but it grows in every soil, and no grass on close, rich land, is more formidable to the cultivator; *it must, therefore, be introduced with caution.*"

Broom Corn and Tobacco.

Would not you think it rather a tough story, if any one were to sit down and tell you about land being worth three hundred dollars an acre because it produces broom corn well? Well, you may think so if you like—but Gov. Hill, of New Hampshire, says it is true. Read the extract below, from his agricultural paper, the "Monthly Visitor."

You will find, farther, that Gov. Hill speaks of land in Massachusetts producing, by the culture of tobacco, a clear profit of one hundred dollars per acre.

Here in the South there is land in abundance that will produce better tobacco, and more of it, than can be made, on the same number of acres, any where in New England. Yet, because a blight has come over the prospects of the cotton trade, men are found among us who are almost ready to yield to despair. This will never do. Our maxim is—never despair. Cheer up, we say; read agricultural papers. If you don't like the "SOUTHERN CULTIVATOR," there are plenty of others. You can be suited among them all, surely. It is not of very much consequence to us which one you take, so you read some one. Get the intelligence of the Yankees; then imitate their enterprise and industry; and you will soon find that there are many other things, besides cotton, by the culture of which you may not only live, but get rich.

From Gov. Hill's Monthly Visitor.

"While the intervale lands at Northampton, Massachusetts, on Connecticut river, devoted to the Indian corn and other grains, with the grasses for hay, bear only an average price of somewhat less than one hundred dollars the acre, the same kind of lands in Hadley, near by, which for years have been employed in raising broom corn, sell for three hundred dollars the acre. Lower down upon the river, in Springfield, Massachusetts, in Suffield and Enfield in Connecticut, tobacco is becoming an extensive article for cultivation. It is said that land in Springfield the last year produced a clear profit of one hundred dollars the acre in the production of tobacco. Spanish and Havana cigars are manufactured in those parts of Massachusetts and Connecticut, where the business has been pursued to great advantage.

"A new impulse has been given to the oldest village in New Ipswich, formerly the residence of the Farrars, the Barretts, Appletons and Prestons, by the manufacture of cigars. Since the use of alcohol has been banished from most of our interior towns, smoking has become a substitute, the excess of which, it may be feared, will be hardly less deleterious in the course of man's whole life than the use of strong drink. The man who smokes ten cigars in twenty-four hours (and some smoke double that number) paying as the price of the best three cents each, will expend as much as the cost of keeping drunk on rum. We believe excessive smoking, chewing and even snuffing to be about as bad as hard drinking: it may not make the man immediately drunk, but continued month after month it must undermine the health—it likewise creates the appetite for strong drink. Fifty thousand cigars weekly, or thereabouts, are made at one establishment in New Ipswich.—The tobacco leaf used in this manufacture, for "long nines" and the cheaper kinds, is raised in Virginia, Maryland or Kentucky: the better kinds are made from the Cuba tobacco, the price of which is much higher than the leaf tobacco raised in the United States. If the appetite for tobacco should continue to increase as it has for the last few years, those who are engaged in its manufacture will accumulate fortunes. Millions of dollars are annually puffed away in the fumes of this narcotic weed. The manufacture of tobacco after it has been cured by the grower, has made fortunes in some of our cities: Jacob Lorillard, who died some years ago in the city of New York, acquired probably more than a million of dollars in the manufacture and sale of snuff and smoking and chewing tobacco.

"In vending the cigars, paste and liquid shoe and leather blacking, writing ink and locofoco matches made at the little village of New Ipswich, Hillsborough county, N. H., some forty or fifty horses and half as many pedlar's vehicles are employed, furnishing the articles in all parts of New England."

How to get Sound Sleep and Pleasant Dreams.

The Albany Cultivator for March says:—"The Hon. J. J. MCKAY, member of Congress from North Carolina, has renewed his subscription for one hundred copies of the Cultivator for gratuitous distribution among his constituents. JAMES SLOAN, of the same State, is also a subscriber for one hundred copies."

When these men lay their heads on their pillows, how different must their feelings be from those of the rabid party politician who will spend thrice that sum in circulating among the people documents filled with the gall and venom of party spirit, the only tendency of which is to poison every source of social enjoyment, stir up feelings of rancorous hate and rabid ferocity, and set man against his fellow man in bitter and unrelenting party conflict—and all for what? That he may be regarded as a great man by those whom he thus brutalises, and may, by their means, get to Washington City as a member of Congress, there to wallow in corruption. Herein we make no personal allusion; but we do say with Colman: "Blessed will be the day, if come it ever should, when every man will learn that his own true prosperity is essentially concerned in the prosperity of his neighbor, and that no gratification on earth, to a good mind, is more delicious than

that which is reflected from the happiness of another to which he has been, himself, instrumental."

The Planter.

If the picture which we hereunto annex had been drawn by any one else than one of our own Southern people, it might be set down as pure scandal; the offspring of malice prepense, as the lawyers say. Even if it were, it might be as well to republish it, that we might know something of what our enemies say of us. As it does not, however, come from that quarter, it will do no harm to examine it attentively, and see whether there is any resemblance between it and ourselves: and if there should chance to be any such resemblance, to set about correcting ourselves accordingly.

From the Wetumpka Argus.

"A True Picture.—The following picture of a Southern planter, as we too often find him, is from a Louisiana paper. There is a deuced sight more truth than poetry in it. By and by, our planters will probably learn a little gumption, and then we shall be happy to see the picture reversed, but until then candor compels us to acknowledge its correctness:

"'Now for the picture of the *planter. He* wouldn't sell a chicken, nor a dozen of eggs, nor a bushel of peaches, nor a calf, for *any* consideration. He is *above* that! *He* raises *cotton* —*he* does! He rides in a six hundred dollar carriage, for which he is in debt. His daughters thrum a piano that never will be paid for. He buys corn which he could raise at ten cents a bushel, and pays sixty cents for it, after 2½ per cent. advance to commission merchant. He *could* raise his own *tobacco*, yet he pays $3 a pound for Richmond scented. He *could* raise his own *hogs*—yet he patronises *Cincinnati*. The consequences are disastrous. Being the possessor of *one* staple, he fluctuates with the market of that article. He takes the 'Price Current'—he pays postage—he gobbles down the English news like a cormorant. If he sells to-day, he'll lose—therefore he'll wait for better advices. He is 'mixed up' in cotton, and is a *gambler* therein. Mean time he wants money—drafts on his factor! He wants cotton goods and clothes for his plantation, that he could make at home. He *orders* them, and feels 'large.' The manufacturer, the insurer, the shipper, the freighter, the drayman, the warehouse man, the seller, and finally the commission merchant, all have a finger in the *pie* of profits, and the proud *foolish* planter pays them all. The year closes, and he is 'up to his eye-brows' in debt! This is the result of his not 'calculating' nor even *guessing* the difference between *farmers* and *planters*. One supports a *family*—the other supports *pride*, until pride gets a fall!'"

That will do for a Louisiana sketch. Now for one from South Carolina. If our people, after such raspings, do not mend their ways, they must be given up as a stiff-necked generation, lost beyond all hope of amendment. Mr. Gregg, of Charleston, says:

"My recent visit to the Northern States has fully satisfied me that the true secret of our difficulties lies in the want of energy on the part of our capitalists, and ignorance and laziness on the part of those who *ought* to labor. We need never look for thrift while we permit our immense timber forests, granite quarries and mines, to lie idle, and supply ourselves with hewn granite, pine boards, laths, and shingles, &c., furnished by the lazy dogs at the North—ah, worse than this, we see our back-country farmers, many of whom are too lazy to mend a broken gate, or repair the fences, to protect their crops from the neighboring stock, actually supplied with their axe, hoe, and broom handles, pitchforks, rakes, &c., by the *indolent* mountaineers of New Hampshire and Massachusetts. The time was when every old woman in the country had her gourd, from which the country gardens were supplied with seeds. We now find it more convenient to permit this duty to devolve on our careful friends, the Yankees. Even our boat-oars and handspikes for rolling logs, are furnished, ready made, to our hand, and what jimcrack can possibly be invented of which we are not the purchasers? These are the drains which are impoverishing the South—these are the true sources of all our difficulties. Need I add, to further exemplify our excessive indolence, that the Charleston market is supplied with fish and wild game by Northern men, who come out here as regularly as the winter comes for this purpose, and, from our own waters and forests, often realize, in the course of one winter, a sufficiency to purchase a small farm in New England."

Dogs.

We made the remark in the January number of the Cultivator, that the first movement of those who were turning their attention to wool growing, should be to exterminate the race of dogs with which the whole country is infested. We say so again; and we add now, that until it is done it is perfectly vain to attempt to raise sheep.

Some one says:—"We can't do without dogs." Very well: if you must have dogs, get dogs that will be worth some small part, at least, of what they consume. The shepherd's dog is of this sort, if half what they say of him be true. Take for proof Mr. Sotham's account of his dog Boxer, in the "Central New York Farmer." Here it is:—

From the Central New York Farmer.

Messrs. Editors—According to promise, I send the description and character of my Shepherd's dog. He is of humble pedigree; his dam was of a poaching disposition, caught pheasants on their nests in the summer, and was shot by the game-keeper, after producing Boxer under a manger. His sire was of a similar kind, caught hares in their forms when out on duty, and although owned by the shepherd of a nobleman, even the influence of aristocracy could not save him; he was hung for his transgressions, although he procured his master many a luxurious meal, and he gave Boxer a good education.

Boxer's phiz is rather a remarkable one; though not beautiful, there is an animated and intellectual look in his eye, and appearance of quick imagination before action, that makes him interesting; he is of medium size, a long, curly coat, and without a tail, a good criterion of the true kind.

This dog is one of the most faithful and affectionate of the brute creation, and I should say, knows as much as many of the human race. His temper is exceedingly docile, except when imposed upon, then he will defend himself with true courage; going through the city, twenty dogs may run, bark and growl, but Boxer will turn, give a counter snarl, and bid defiance to all.

He will go round any lot on the farm, and fetch every sheep to you, and keep them together until you examine the whole flock, or take any number from it. He is generally very obedient, and a more industrious animal never stood on legs; he is more useful in driving a flock of sheep than three men. If his assistance is required among the cattle, he will take them to any point required, and he knows a strange animal equally well with myself. Boxer is no friend to hogs; if he sees one on the premises, out of the stye, he is off without orders. If the peacock, fowls, turkeys or ducks enter the garden, Boxer discovers them, or if a whistle is given, they take to their wings or legs immediately. Should the geese enter any of the lots, a whistle will soon bring them into the road. Once show Boxer the proper place for an animal, and he will always bear it in remembrance. Make him understand what you want him to do, and he will perform his work with great sagacity.

It is sometimes my practice to let my sheep in the road a few hours in the day, when the feed is good, and take them at night to very short pasture, to leave the manure they collect; one evening, Boxer going to fetch them, brought all but one; as soon as they had entered the gate, he barked at the shepherd, and walked towards the lost sheep, the pastor followed him to a fence where a lamb was fastened; had he remained, he must have died before morning. Two flocks of sheep came to the washbrook at the same time, into one yard, Cotswold and Merino.—Boxer kept the division equally well as a board fence, not a sheep escaped from either, the whole time of washing. The old dog did this with much judgment, and in a very quiet way, and the good acts he had done elsewhere, elicited many *compliments from his friends and "acquaintances."* Give Boxer a fair chance at a rat, and he is certain death. A "*skunk*" must die, notwithstanding its odor; a woodchuck must run, if he has far to get home; and a dog must fight—and bravely too—if Boxer catches him among the flock.

He comes to his meals as regularly as the cloth is laid, and if he is not noticed, he will put his paw on each at table, until he is fed.—He fares as well as his master, who is perfectly aware of his partiality and sterling worth, and well compensated for every meal. He is a more interesting companion than many who call themselves men. Boxer sleeps before the fire in the evening, and has nothing to disturb his tranquil repose, but the caresses of his friends—at night he guards the premises—not a thing moves without his knowledge—and a "*thief*" must take care of his "*breeches*"—the midnight solitude finds the old dog watching. He is a dog of all work, a general favorite, and never flinches from his duty, but manifests eagerness to do it. If the old dog could speak, he could tell a good tale on sheep. If he could flourish a pen with his paw, he could distinguish the *different breeds of cattle*, equally well with many writers who profess to know; therefore I shall bestow the praise and commendation, and to say the least, he is a great dog. I have been offered one hundred dollars for him, but my "*last shilling*" must go before we part; there is a tie between him and me, that even the power of money cannot sever. Wm. H. Sotham.

Hereford Hall, Nov. 10th, 1844.

Ellsworth's Report.

We are indebted to the Commissioner of Patents for a copy of his Report for the year 1844. It embraces the usual topics; and is, from first to last, full of very interesting information, particularly so much of it as relates to Agriculture. We intend to avail ourselves, from time to time, for the benefit of our readers, of the very important and valuable matter which Mr. E. has collected with so much industry. We commence, in this number, with the following extracts from his introductory report.

From Mr Ellsworth's Report for 1844.

The annual agricultural statistics, comprising the tabular estimate of the crops for the past year, with accompanying remarks and appendixes, will be found subjoined, (marked D.) If the length of the document is objectionable, I will only say that I have deemed it more acceptable to the public to give the facts established, than deductions from them; more especially as no conclusive opinion can be justly formed on contradictory statements respecting some important subjects.

The science of agriculture has now become a study, and much greater improvement may be expected. Worn out lands that have been, as

it were, abandoned, are now being reclaimed under scientific treatment. Guesswork and hereditary notions are yielding to analysis and the application of chemical principles. The writings of learned agriculturists in Europe are translated into the English language, thus pouring a body of new light upon the path of the husbandman.

Some extracts from the celebrated Von Thaer's principles of agriculture will be found in one of the appendixes to the agricultural report. They evince the deep research and patient investigation of that distinguished philanthropist.

Little is accomplished in any science without perseverance. How many bright anticipations have been blasted by a single unpropitious experiment! Without making allowance for ordinary casualties or unforseen occurrences, how many efforts to improve husbandry by selection of seeds has failed! All has been abandoned, because the first experiment has not been crowned with success; forgetting that seeds, like animals, must be acclimated, and require certain food not found in every soil. The truth of this general remark may be illustrated by a recent attempt to solve the difficulty in granulating the sirup of corn-stalks. Scientific gentlemen at first pronounced the sugar from corn-stalk to be grape sugar only; and hence, crystalization could hardly be expected. Much disappointed in the result, I transmitted to Boston some of the sugar made by Mr. Webb, of Delaware, and requested another analysis. The second analysis was entirely successful, proving the sugar from corn-stalk to be equal to the best Muscovado sugar.

In reviewing this subject, it appears that the juice of cork stalk cut too *early* will not granulate; and this was the cause of the first failure. There is every reason to believe that all difficulties in making good sugar from this vegetable will be removed; while the reports of this year show the quantity of saccharine matter sufficient to class the crop among the best for profit. * * * * * *

To Dr. Jackson we are also indebted for an analysis of several grains. The superiority of one kind of Indian corn over another is surprisingly manifest: one is filled with oil, the other has no trace of it; hence the superiority of the former for fattening animals. Some grains contain a large quantity of phosphate, (such as beans, &c.,) and hence their consumption tends to increase the bones of animals. Dyspeptics will learn from this why some meal (that which contains oil) is so difficult of digestion. For further remarks on this subject, with illustrations, see Appendix No. 6 to the agricultural report. * * * * *

Among the first inquiries of the political economist, is the question, How can the productiveness of the earth be increased? Modern practice answers it easily. Manure and tillage are the instruments employed; either, alone, is comparatively useless. "Grapes will not grow on thorns, nor figs on thistles." Nor will sour land yield sweet food; the nature of the soil must be changed, and this is effected by draining

Intimately connected with draining land, is that of subsoiling; indeed, the last has lately been substituted for the former, with good success. The cheapness of sub-soil ploughs brings them within the reach of every farmer.

The letter from Mr. Verdine Ellsworth shows what can be done by deep ploughing. By superior culture, his land yielded this year over 121 bushels of shelled corn per acre—his timothy meadows yielded 3½ tons per acre. This statement is full of encouragement. (See appendix No. 5 to agricultural report.)

Few individuals are aware of the extension of roots in pulverized soil. Von Thaer mentions finding roots of sainfroin from 10 to 15 feet deep in the ground. There are now in the national gallery corn-roots taken from one side of a hill of corn laid bare by the freshet, and presented by the Hon. J. S. Skinner to the national gallery. The corn was planted on the 20th of May, and roots gathered the 14th of July, 1842. In sixty days some of the large roots extended more than 4 feet, covered with lateral branches. I have caused the roots to be measured; the aggregate length of roots in the hill is, by Mr. Skinner's estimate, over 8,000 feet. The specimen alluded to is open for examination. This fact is here mentioned, to show the importance of deep ploughing, to enable the plant to find nourishment so much below the surface as may avoid the effect of drought, give support to the stalk, and not expose the roots to be cut by needed cultivation. Soil is made by exposure of earth to the atmosphere; and, whoever wishes to make permanent improvements will not fail to *plough deep*. * * * *

The Hessian fly still continues to be a dreadful foe to the agriculturist. Hoping to throw some light upon this subject, I have obtained a communication from one of the most scientific gentlemen in this country, who has made the study of this insect the object of microscopic investigation for years. The origin, progress and changes of this fly, cannot fail to interest; and it is confidently hoped that when its birth, its constitution, and its home are found, it can be attacked with more certainty of destruction. Mr. Herrick's communication will be found in the appendix to the agricultural report, as above, marked No. 1. Notice of other insects that affect wheat is added.—(See Appendix No. 2.)

There is much to encourage the artist and the husbandman. The latter may feel momentarily depressed, by the low price of crops; but he is cheered by the reflection that he is far better off than those in professions proverbially crowded. The cultivator of the soil is, in the fullest sense, the most independent: he raises enough to eat, and can clothe himself; having a surplus to exchange, if he cannot sell. How much better for the young man of this country to aspire to the enviable rank of a scientific and successful agriculturist, than to grasp at the shadowy honors that are momentarily cast around the brows of political combatants.

There is much to console the husbandman in the reduction of the cost of the necessaries of life which he has occasion to purchase.

Labor-saving machines are being introduced with still greater success. Mowing and reaping will, it is believed, soon be chiefly performed, on smooth land, by horse power. Some have regretted that modern improvements make important changes of employment; but the march of the arts and sciences is onward, and the greatest happiness of the greatest number is the motto of the patriot. This is promoted by facilities in production, whether in manufactures or agriculture; and if we are to compete with the world at large, we must readily embrace the offer of genius and skill; we must yield to competitors equal fertility of soil, and win the race by superior industry and intelligence.

ELECTRICITY.—I have frequently heard it remarked, and believe it is generally known (by observing people at least,) that for the space of ten or twelve years past, there has not been so many thunder showers as formerly, say from ten to twenty years ago. I think that where I reside, (30 miles N. W. of Boston,) there have not been so much lightning and thunder in any three years since 1835, as I frequently knew previous to '35, in 24 hours. Do you think that the vast quantity of iron on our Rail Roads and in our manufacturing villages has any influence in this respect? I think it has, the Rail Road in particular. I have learned that in the northern part of this State, (N. H.,) there is no difference from former years. I should like to have the opinion of others on this subject. C.

Editorial Remarks.—We should be pleased to have the views of our correspondents on the above subject. If the large amount of iron exposed to the atmosphere conducts off the superabundance of electricity imperceptibly, what effect will it have on vegetation?—*Boston Cult*

Examples for Planters.

MR. EDITOR:—On a recent tour on business down the Chattahoochee, I found the people every where alive to the important question of, What shall be done by the South to relieve the embarrassments resting upon her great staple? Many plans have been suggested, and probably all of some merit. While passing among my planting friends, a few facts fell within the scope of my observation, which led to reflections on this subject, which I think are practicable and proper to be adopted.

At Eufaula, I was invited to the house of Col. McDonald, who is getting very justly some notoriety as a spirited planter, and the warm and zealous friend of all that tends to the improvement of agriculture. He showed me samples of his cotton, which was brought to that market when ordinary cotton was selling at 4 cents. For this he was promptly offered 7 cts, which he as promptly refused. It was shipped to New York, where 9 cents was at once offered, and again refused. This cotton, I learn, was raised upon common grey land; and its superior quality was attributed alone to the handling, which he represented as tedious, so much so, that the quantity of land planted, and the quantity of cotton picked, was necessarily greatly less than that ordinarily planted and picked to the hand. His profit, for neatness and pains taking, as you will perceive, was just 75 per cent.: so that he could well afford to reduce the number of acres cultivated, and the number of bales produced in the same ratio, say 75 per cent. on each, and still make as much money as his neighbor who pursued the old plan. If this system was adopted generally, or more extensively, the relief to the country in a reduced crop is found at once, without the sacrifice of a single dollar in its accomplishment, and with a due share of all the advantages, which it would soon be instrumental in bringing to the country, as an inevitable result, in the reduced production.

The next day I passed to the house of Judge Taylor, in the County of Randolph. The Judge is living on his farm, in the neighborhood of Cuthbert, and is full of the spirit which a personal and practical knowledge of planting is so well calculated to beget. He invited me to see his process of making syrup or molasses from a little patch of sugar cane, which he had cultivated last year. Every body knows that molasses may be made from the cane, and this is not therefore the fact which I propose to report, but the yield This is the point of interest, and I doubt not will be of astonishment to nine-tenths of those who hear it. He had cultivated not quite three-fourths of an acre in cane, (common ribbon,) on very common pine land, a little manured. At the time of my examination, he was just filling the second hogshead of 80 gallons each; and said that he had cane enough to make 40 gallons more—making 200 gallons of good syrup—and had seed cane enough left to plant 2½ acres. This would be at the rate of nearly or quite 300 gallons of syrup to the acre, appropriating from the crop only seed enough to plant the same quantity of land again. This, at 20 cents per gallon, would be $60 per acre; and he assured me that it was not more difficult of cultivation than Indian corn, and the process of boiling not half so tedious or complicated as the making a kettle of soap. The mill for grinding the cane, is a simple and cheap affair, which can be put up by any rough workman, and need not cost a planter more than ten dollars.

Here is an outlet for a change of labor and a good return in profits. Ours is indeed a country of resources abundant and varied; and if, in the midst of them, we shall continue to work out, by a blind policy, our own oppression and ruin, I can only conclude that we deserve to groan on under the burthens of our own creation.

Very respectfully, your obd't. serv't.,
Wynnton, Ga., Feb 22. JAS. M. CHAMBERS.

For the Southern Cultivator.

Mr. James Camak, Editor of the Southern Cultivator:

Dear Sir:—I have received the January, February and March Nos. of the Southern Cultivator, and have read them with much interest, and, I trust, with profit. I have also the first two volumes of that valuable agricultural publication; and I am much pleased that the farmers of the South and Southwest have it in their power to procure a work, devoted to the cause of Southern husbandry, so cheap as to be within the reach of the entire family of the cultivators of the soil, and one so well calculated to interest and benefit the farmer. I make this remark after having been long a subscriber to agricultural publications, and being, at this time, a subscriber to three other agricultural works beside the Southern Cultivator: and as an evidence of my opinion of the value of the Cultivator to the farmer, the gardener and the mechanic, I have, since the commencement of the present volume, procured and sent to the publishers upwards of seventy dollars for the Cultivator. The subscribers have been mostly farmers, but several have been mechanics, and others that cultivated only a garden.

I was sorry to observe, in the February number of the Cultivator, that the publishers had to publish to the world, that they had not received more money, up to that time, than would pay for the setting up of the type. Now, this should be mortifying to every Southern farmer. At a time when a state of things has taken place throughout the entire South and Southwest, heretofore unknown since the introduction of the great Southern staple, we, for the first time, see cotton pressed on the market so low as hardly to leave the farmer or cotton grower any money, after paying for his bagging, rope, and the transportation to market of that troublesome crop; at a time when the cultivators of the soil need all the light they can possibly get; when they require all the information within their reach to enable them to shape their course so as to make their honorable and important business pleasant and profitable—to see so little interest taken in the circulation of the only agricultural work devoted to their interests in this region of country, is a matter that I must acknowledge I was not prepared to see. But I trust a better state of things has taken place, and that there is a coming up from every quarter subscribers to the Cultivator.

If we, as farmers, would take the same interest in the cause of agriculture as was taken last year in President-making, but a few years would pass away until the face of the country would change. You would not be accosted at every turn of the road with the cry of hard times. Prosperity and happiness would become universal. Our old fields, now thought to be worthless, would be so improved, by a proper system of manuring and rotation of crops, that we would hardly realize that it was the same place that, a few years before, was considered worthless. Tell me not that this is a too highly drawn picture. The same thing has taken place in other parts of the world that have not the advantages we possess.

Mr. Editor, I am far from believing that we should be indifferent as to the selection of our rulers. I only call on the cultivators of the soil to be as industrious now in the formation of Agricultural Societies, and in holding Agricultural Fairs, and in the circulating of Agricultural papers, as they were in the cause of politics. The great misfortune is, we are opposed, as farmers, to every thing like innovation on an established system, if system it can be called. As soon as an improvement is suggested, we cry out humbug. Now, Mr. Editor, for my part, I would rather be humbugged a little in trying to be, or to do something, than to spend a life in attempting so little as never to attain to a decent humbug.

The farmers throughout this region, many of them, are not only taking the Cultivator, but are forming Agricultural Societies.

I will, at a future time, give you some account of my farming operations, as I keep a farming memorandum, in which is entered every thing done on the farm from year to year. This is a work that I have kept for twenty years past.

Your friend, Alexander McDonald.

Eufaula, Barbour Co., Ala., March 12, 1845.

Every mechanic that has a spot of land, though it be *small*, should raise some fruit, both for pleasure and profit.

For the Southern Cultivator.

Berkshire Hogs.

Mr. Editor:—I have just received your "Southern Cultivator," volume third and third number, and have been a little amused at a communication which it contains from "Clodhopper, of Houston county." Together with a good many other things, he says: "I want to know the breed of hogs that will give the most good meat for the food consumed; how to feed, and what to feed with, to produce flesh and make fat. But spare, oh, spare the Berkshires; they have brought me to buy pork." Sir, the above lamentation reminds me very much of a gentleman of my acquaintance who called to see me sometime during the last year. In the course of conversation, the breed of hogs was brought up, and, like "Clodhopper," he condemned the Berkshires. I took him into my back yard, and showed him a pig I had, which is three-fourths Berkshire. He admitted it to be a fine pig of its age, but was fearful it would never be large enough. We continued our walk, came upon a Berkshire sow and boar. The boar I suppose would weigh net four hundred and fifty, and the sow three hundred pounds. Well, sir, said I, will they do?—O yes, they are fine—they are large enough. We still pursued our walk until we came up to a sow, half Berkshire, the balance improved stock, that I supposed would weigh net five hundred pounds at any time when fully fat! My friend was much delighted with her. The hogs were there, and showed for themselves. *His* theory was put to flight by *my* demonstration; he could say no more, but, turned off and said, "Ah, you *feed* your hogs." Now, sir, if "Clodhopper" thinks that he can dispense with the use of corn, or a good substitute for it, because he changed his breed, he will find himself always a pork buyer.

And here permit me to say, that there are many hogs in the country, that have been put on the people for Berkshire, that have but little, if any, of the stock about them. Some years ago I received, as a present, a pair of pigs from a gentleman of my acquaintance, of Montgomery county, Alabama. My hogs were much improved by the cross, and consequently were considered the best in the neighborhood. Mind, I do not say the *largest*, but *best;* I mean by this that they were considered of fair size, and would yield the most flesh to the size of the bone and quantity of food consumed. I have since crossed them with the Berkshire. My neighbors think my stock still better; but, recollect, I feed them. I have the full blood Berkshire, and prefer them to the cross upon common stock. I never anticipated so great an advantage as many others expected.

I expected to get a hog of small bone, a good deal of flesh in proportion when fat; one that would be easily fattened, and that *could* be fattened also at any age; and, sir, *I* have not been disappointed. Now, sir, if "Clodhopper" is disposed to feed, and wishes to change his stock by a cross, I will venture to advise him to call on Col. David Bryant, near Belvue in this county, and obtain from him a pair of Kennelworth pigs. They are large, *plenty* large; will weigh, when fully grown, from five to seven hundred pounds, (but mind, he feeds them.) They are generally perfectly white, very fleshy, and none too much bone, and can be fattened at any age. All things considered, I prefer them to any hogs I know of. If I have any objection, it is that they may be too large for our climate—small hogs being the easiest to save. But then you know that difficulty could be obviated by killing them while young.

While upon this subject, I will say, that I have no doubt of "Clodhopper's" getting well paid for his trouble and expense, by feeding his hogs on meal instead of corn when they are put up to fatten. This I have tried to my satisfaction, and I am fully persuaded that *at least* 33 per cent. may be made by adopting the plan of putting up hogs on a floored pen and feeding on meal, instead of letting them run out in a lot and feeding on corn. Gentlemen of the North say: Cook your food and you can save 33 per cent. by that. Of this, however, I am not prepared to say, not having tried it to my satisfaction, but my intention is to test the matter this fall, by using pigs of the same litter; yes, even Berkshires if you please, and should I live to do so, you shall know the result.

I have tried a cross of the Durham cattle on common stock, and find a decided improvement in the milking qualities—the mixed stock yielding more than double the quantity of milk that the common stock does, with precisely the same treatment. This emboldens me to push my experiment even as far as the full blood, but as this is yet to be done, I can say nothing of the result. One of the Buckets.

Talbot county, March 13, 1845.

For the Southern Cultivator.

Cotton Culture—Successful Method.

Mr. Editor:—The subject of agriculture advocated by your valuable paper, the Southern Cultivator, is becoming every day more interesting. In all parts of our State we hear of experiments being made by our most enterprizing farmers, the success of which, suggests to others the importance of making similar efforts, and if possible, of improving those made already. By communicating to the public the success, or failure of our experiments, we not only open the way to insure success to others in their undertakings, but also set up a beacon, which will tend greatly to prevent many from running upon the rock of disappointment, and, not unfrequently, discouragement. Whether the publication of *my* manner of planting, manuring, and cultivating five acres of common pine land, will be of any benefit to the planting interests of Georgia, I will not presume to say; but must only hope, that others will pursue the plan with increased success.

I will state, in the first place, that my land would produce, without manure, about six hundred pounds of seed-cotton per acre, provided the season were favorable to its growth: and, in the next, that my cattle had been fed and penned on the land. I will now proceed with my manner of planting, manuring, &c. My rows, I ran off on the plan of Dr. Cloud, that is to say, three feet by five, running the narrow way with a scooter, and the wide way with a common shovel, and trench-plowing it with the same plow. I then applied ten ox loads of well rotted lot and stable manure per acre, depositing against every scooter furrow, a shovel-full to two hills, and following with a turning plow, covered the manure, by running a furrow on each side of that made by the shovel. This I did about the last of March. On the 5th of April, I planted my little field by opening the beds very shallow with a small scooter; and having first rolled the seeds in leached ashes, dropped against the scooter furrow, and over the manure, ten or twelve seeds in each hill, and covered them with a hoe. With the exception of a small portion of the field, there was a very good stand. After the cotton was up, and of a suitable size, I plowed the middles close and deep with a shovel, having first run round it with a scooter. I immediately followed with the hoe, thinned it to two stalks, and put to it a little dirt. After this we had a long drouth. When I considered my cotton out of danger from the cut-worm and other insects which sometimes prey upon it, I again, with the hoe, put a little earth to it to prevent its falling, and thinned it to one stalk. This was the last of May. We then had a heavy rain; the ground becoming very wet, several days passed before I plowed my cotton: for I never thought it was good policy to plow soon after heavy rains. The after cultivation consisted of two plowings with the sweep, and sufficient hoeing to keep the cotton free from grass. The result of which was, my field yielded 2060 pounds per acre, being 10,300 lbs. raised on the five.

My object was not so much to see what amount I could raise from one acre, but to make the most I could of my manure by spreading it upon five acres. I planted the Texan burr or bunch cotton. CALVIN LEARY.

Houston Co., Feb. 10, 1845.

For the Southern Cultivator.

Manure.

MR. CAMAK:—I am but comparatively a new farmer, and as my readings have not been much agricultural, I am a novice in husbandry: nevertheless, I shall go by the best knowledge I possess of this primitive and fundamental science and *profession.*

Every farmer, by strictly reflecting and meditating on his business, fully as much so as the lawyer on his *tomes*, the doctor on his pharmacy, and the mechanic on the *improvability* of his machinery and structures, cannot fail to become somewhat of a Kliyogg, a peasant in Switzerland, who renevated exhausted hill-lands, and rendered himself and household thereby affluent. He was called the rural Socrates.

But in general every body is attentive to his business but the farmer. Having an extensive Western country, a Texas, a Florida, and even an Oregon and a California, to settle; living contiguous to gold mines, &c. &c. &c., the American farmer, especially around about this section, appears to be the *last man* that will attend properly as he ought to his occupation! As necessity is not only the mother of invention, but also of careful and assiduous enterprise, never, I fear, until our spare regions of luxuriant tracts of land be *surcharged* with a redundant population, will the Georgia farmer begin to imitate the Yankee, or the English and French agriculturist. Still something may be done by those who are determined to abide and die on the soil of their native State.

The first and *almost the only* necessity here, is with regard to manure. My maxim is: *take care of your fences and the crop will take care of itself:* and a consecutive addition is, and no less cogent: *take care to provide abundant and well preserved manure and your cribs will always have enough*, not only to subsist upon, but to sell.

In a hilly region, so subject to washing during *every* heavy rain, whereby the rich soils of newly cleared grounds, no longer supported by the natural growths and leaves, are carried off in, and even in opposition to, the plow ridges—leaving nothing but red clay to meet the contemplation of the planter, giving growth, mainly, to broom straw, it is virtually impossible for any one to thrive without manures—and yet how few of our people ever think of manuring such wastes, good alone for brick-making. The cry is Westward Ho!—and fields are cleared and then exhausted, and the inhabitants are, at the crack of the wagon whip, moving for Alabama, Mississippi, &c.

Soon Alabama and Mississippi will be reduced to the same extremity; and if the emigration be for Texas, in spite of its alluvial deposits, the same thriftless culture will make that bountiful country too a waste! Not to use manure is too improvident for Providence to bless. Resource there is none, whatever, if men do not *manure* and improve their *hills*, except cheating or stealing. And I have no doubt, many in the calendar of crimes owe the origin of their folly to inattention, at the outset, to agriculture—at the time of clearing land to keep it always rich—hence want, &c.

Manure is the grand consideration: without that at the basis of every project, you may talk as long as you please about planting, plowing, harrowing, &c., nothing else would do. The best invention of ingenuity as to plantation *tools*, the best horses and mules, are of a very inconsiderable value. And he must be "moon struck," or "have eaten of the insane root," who relies on the latter without the former.

Luckily for us, who live on these old red gullied hills, sometimes nearly precipitous, all is a *compact clay*, and will not slide like sandy or loamy grounds; and being thus so tenacious, manure, deposited and well covered or plowed in, *will be retained for years by the stiff clay*, and repay fertilely the labors of the farmer. If a plentiful supply of this vital property of our fields could be obtained, the wastes around us would bloom like a garden.

But it "*cannot be obtained!*" Of course then the argument drops to the ground. It cannot, indeed, be obtained by inadvertent ignorance. It can be made, however, and accumulated by industrious wisdom; for the deriving and preservation of manure is an art and a science, no less than chemistry itself—one quality of which it is.

Guided by the advice of Sir Humphrey Davy, that heat and dryness evaporate the fertilizing properties of manure unless limed or gypsumed; and by that of Dr. Justus Liebig, that water is very decomposing; and decomposed manure, otherwise than in the ground, covered for cultivating vegetation, looses its strength—the sal ammoniac, which is the living principle of all vegetables—the wise and sedulous farmer would collect all the manure he can at his stable, barn, and in his yard, on a wet day, and deposit them all under some good booth or shed, fit for use when the planting season arrives. They would then be free from drying, and exempt from extraneous water, and retain their own radical moisture.

An improvement on this plan would be, to apply some bushels of lime, gypsum, or plaster of Paris, to the heap, just as it is shovelled out of the wagon. This I intend to do so soon as I can command money that I can call my own, by virtue of owing no man any thing but love, and a good example, wherewith to purchase these indispensable articles. Yours,

J. J. FLOURNOY.

Wellington Farm, Jackson co., Feb., 1845.

Agricultural Meeting in Putnam.

HELD, MARCH 18, 1845.

At a meeting held by the citizens of Putnam county in Eatonton, in accordance with previous notice, to form an Agricultural Society, and also to appoint delegates to represent this Society in the contemplated Agricultural Meeting o be held in Milledgeville on the fifth Monday in this month—upon motion, Samuel Pearson, Esq., was called to the Chair, and C. S. Credille requested to act as Secretary.

After some appropriate remarks, Wm. Turner, Esq., submitted the following resolutions, which were adopted, to wit:

Resolved, That this meeting form itself into an Agricultural Society, and proceed to the election of President, a Vice-President and Secretary; the latter of whom shall be Treasurer.

Resolved, That the Society forthwith appoint one delegate from each district in the county, to represent this Society in the proposed Agricultural Meeting to be held in Milledgeville on the fifth Monday in this month.

Resolved, That a committe be appointed to draft a constitution for the government of this Society, to be reported for consideration at our next meeting.

The Society then proceeded to the election of officers, in accordance with the first resolution; whereupon, Samuel Pearson, Esq., was elected President, John Farrar, Vice-President, and C. S. Credille, Secretary.

They also appointed the following delegation to the contemplated Agricultural Meeting in Milledgeville—Wm. McKinley, Wm. B. Terrell, Wm. Turner, Samuel Pearson, Alexander B. Harrison, Robert Ladd, Wm. Garrett, Pleasant J. Mullens, Lewis H. Linch, Wm. Farrar, Alexander C. Maddux, Wm. Hearn, John Copeland, Irby Scott, John A. Cogburn and Nathan Bass.

On motion, the Chair appointed a committee of five, viz:—Wm. Turner, Esq., A. D. Gatewood, B. W. Johnston, Thomas Turner, jr., and Nathan Bass, to draft a constitution.

On motion, the first Tuesday in next month was appointed for our next meeting.

The list was then opened for the reception of members, and a large and very respectable number had their names enrolled.

Resolved, on motion, that our proceedings be published in the Milledgeville papers and the Southern Cultivator.

The Society then adjourned.

SAMUEL PEARSON, Pres't.

C. S. CREDILLE, Sec'y.

BUTTER.—There are few departments of rural industry, in which there is so much room for improvement, as in the business of *converting milk into butter!* This will be admitted, readily, by all who reflect, on the very small proportion, which really pure, well-flavored butter bears, to the whole quantity exposed for sale in the common market, or to that which is produced in the country.

The defective quality of butter arises no less from want of care or skill in the management of the milk—probably much more from that cause—than from any effect upon the milk, resulting from the difference in the pasture and food of the cow; although the latter has, doubtless, a powerful influence So sensible are they of this influence in Scotland, that we observe among other curious objects, never thought of in this country, a premium has been offered there for the best essay *on the influence of food on milk and butter.* We cannot but suppose, that the superiority of the butter in the Philadelphia market, arises, in a great degree, from the nature of the pasturage; consisting of long established "English grass" meadows. He who will take the trouble to make the calculation, will be struck with the increase of national wealth which would accrue from an improvement in the quality of our butter, from whatever cause, that should add a few cents to its selling price, without saying any thing about the increase of the quantity which could be easily obtained, by more careful milking, and a better system of dairy management.—*N. Y. Albion.*

WINTER BUTTER.—Mr. Judge Kimball, of Lindon, Vt., has shown us some excellent butter made in December last. It is yellow as most of the tubs that are made in June.

Mr. K. tells us he scalds his milk before setting it for cream; and his mode of scalding is to heat a quantity of water in his boiler and set the milk pail in the hot water—not boiling—till the milk has become thoroughly warm. It is then set in pans in a dairy where the heat is kept uniform at about sixty degrees.

We think this is a better mode of making winter butter than scalding or freezing the cream. —*Massachusetts Ploughman.*

A GOOD COMPOST FOR SANDY LAND.—Take 10 loads of stable or barn-yard manure, 5 loads of clay, 10 bushels of ashes, and 20 bushels of lime, mix the whole well together, let it remain in pile a few days, turn it over, when it will be fit to apply to the land.

The above quantity will make a better dressing for an acre of sand than twenty, or even twenty-five loads of stable or barn-yard manure alone, and will last longer. Let any one who may doubt, try it, and they will be convinced of the truth of what we say.

EGYPTIAN CORN.—Robert W. Williams, of Tallahassee, Florida, in a letter to the editor of the American Agriculturist, dated Nov 13th, 1844, says: "One word about Egyptian corn. It is now green, with a crop of from five to eight heads from each root more than half matured. This, should it mature, will be the fourth ripe seed that has been gathered from one planting. From the manner it continues to send up shoots from the old root, I am induced to try if it will not rattoon next spring, by protecting it this winter.

"The low price of the great southern staple is having the happy effect of causing proprietors to give more of their personal attention to their plantations; and, as a natural consequence, producing a taste for the science of their profession, and a demand for agricultural publications and improved implements."

From the Boston Plowman.

Horse Breaking.

There is a difference of opinion among horse dealers in regard to the time when you should commence showing your authority over the motions of the young horse. Some contend that they can be better broken after being allowed to run perfectly free for three or four years; while others insist that there is danger of their becoming self-willed if they are not compelled to submit at an earlier age. One point is certain: it is best to let the colt run perfectly free until the time comes when you have the leisure to control him completely and effectually. Half-breaking is worse than no breaking; orders once given must be obeyed or orders would be better withheld.

The first step to be taken, in breaking a young horse, is to convince him most satisfactorily that his halter is stronger than himself. If he breaks his first rope he will never forget it; you may fasten him afterwards a hundred times with a timber chain and he will make a hundred attempts to break it—because his memory is better than his judgment. He must not be suffered to break loose, at the first tying, on any consideration whatever. We often see very gentle horses that will stand quietly in harness for hours, if you attempt not to fasten them; yet they will give your halter a try as soon as they find you have attempted to make them fast. This will never be the case if you have done your duty in halter breaking.

HOW TO MAKE A HORSE GO.

The next step is to teach a horse to move at your bidding. For unless you can do this it is of little consequence whether you can fasten him or not. A well broken horse will move when you desire he should, either forward or backward.

You must be extremely cautious how you issue your first orders to "move." You must not expect to be able to drag your horse after you until he has become used to following—you cannot even "lead him to drink" unless he wills to follow, and his will should be won by kindness, unless you prefer to rule always by brute force.

After your colt is fairly halter broken—after he has been made fully sensible that your power, at the post, is superior to his, you will do well to coax him to move, either by inviting him to eat something agreeable, or to follow some agreeable company. You may tie his halter fast about his mother's neck, and he will walk by her side; or you may tie him to the shaft of the wagon to which she is harnessed, and let him travel with her.

In some districts we find colts of four months old travelling with much regularity and order by the side of the mother that carries the family to meeting in the chaise. The colt's halter is made fast to the fore end of the shaft, and he is kept out of mischief, more effectually than some children are, during the whole of the service. Colts that have been taught to go to meeting are half broken; whereas if they were allowed to run perfectly free, going to meeting would be of no service.

Now your colt is taught to stand and to move at your request; after much repetition he will acquire such a habit of obedience that it will be natural and easy to him. Before he is old enough to draw a load you can place a harness on him and let him become used to that. He should never be allowed to draw hard when young. Nor should any burthen, heavier than a saddle, be placed on his back before he is three years old. Some owners will not allow a grown man to ride before the colt is four.

BEST AGE FOR BREAKING.

We cannot see but one objection to halter breaking while the colt is quite young, and that is the temptation to back him before his spine has become strong enough to bear a great weight. The owner must guard against such an abuse, and he will then have a horse more kind, more gentle, more safe, and more certain in draft, than if his colt were allowed to run wild till three or four years of age. In addition to this, the labor of breaking will be found less if you commence with the first summer; and young colts bear restraint with less repining and loss of flesh than full grown colts.

When you first put a young horse to drag a load, be quite sure it is a light one. Never let him conjecture that his load can keep him back. Teach him to proceed till you command him to stop, and mind that he stops on ground where he can readily start again. Speak plainly and distinctly to him. Say "whoa" when you mean whoa, and say "go" or "come," or something that sounds quite differently from whoa, when your meaning is different.

We have had high spirited horses that would stop at once, by the word of mouth only, when the harness failed and the reins were broken—when the sleigh upset, and when the chaise broke down. With such horses you feel more safe than when you depend wholly on the rein, or your blind bridle. You have a double chance of safety in case of accident.

BACKING OUT.

Horses as well as broken oxen should be taught the art of backing. How much we are troubled to back some carriages out of a shed! A young horse should be taught to walk backward, while in a cart or chaise, where the ground descends and where he can easily follow. It is almost as easy to teach him to go back as to go forward. Speak to him—say "back," plainly, and use such plain language as an Irishman can understand.

From the Boston Cultivator.

Poultry.

A correspondent in Richmond, Me., contemplating to keep a large number of fowls, makes inquiries as to the best breeds, mode of management, the number that may be kept together, the best grain raised in Maine for food, &c. &c.

Although we have kept various breeds of fowls, we cannot determine which is best, and if inquiry be made of those who pay much attention to the subject, we find that opinions are as various as they are about the kinds of cattle. If we consult our poultry books, they only describe the different varieties, leaving the reader to make his own decision. It is the same with fowls as with different kinds of cattle, one excels in one thing, another in another. It is difficult to find all the desirable qualities united in one breed.

The Polands or *Top-Knots* are among the most noted birds. They are middling size, very beautiful, good layers, excepting in cold weather, and not inclined to sit. Their flesh is excellent, but not good for the market, as their legs are black. They are rather tender, and the young chickens not so easy to raise as those of the hardy races. This bird is seldom found pure in New England, where people are noted for attempting improvements by mixtures.

The Dorking's are a famous breed, combining several good qualities. Good layers, sitters, nurses, and their flesh is good. Their legs are generally of a light or flesh color, having been bred in England where this color is preferred, yellow being the most objectionable color in that country. These are seldom found pure long after they have been imported. Some prefer the large white, others say they are too coarse, and give their preference to the small white, still leaving room for other opinions in favor of the speckled variety.

The Buck's County is a large, hardy race; and though the chickens have hardly any feathers till they are 4 or 5 weeks old, being as ugly looking as a toad, yet they are hardy. This bird is large. We have seen capons in this market from Pennsylvania, about 18 months old, that weighed, dressed, 19½ lbs. a pair. They often astonish the *Natives* who inquire, "what fowls are these?" being puzzled to tell whether they are *turkeys* or *geese*, never thinking that they are hens. When these chickens are about half grown, they are as large as other birds nearly full grown, and will sell well to persons who do not know what is good to eat neither before nor after it is cooked. Their flesh is hard and coarse-grained, and they are long in coming to maturity. They will answer for soups, broth, and stews. They are not very good layers and their eggs are small for fowls of a large size.

The Game breed is the best fighters. But since men have left off fighting themselves, they are not inclined to rear fowls for cruel sports. They are good layers and are remarkably hardy. Their flesh is the finest of any. But they are so pugnacious that the male chickens often kill one another. A little touch of this breed is well in the chieftain of a flock, to give him a marshal bearing. We have a noble *crow biddy* which has a tincture of this blood; but he does not fight, for he never runs after those who are disposed on his appearance to trust to speed for safety. One-sixth or one-eighth of this breed is enough in a class of animals that have as high a *sense of honor* as a duelist.

The Boobies are valued by some, but we think that they are too clumsy and coarse; they lay small eggs for large fowls, and they are tender; the chickens are difficult to rear.

The Guilderlands are called fine fowls, but they are as yet but little known, and their peculiar qualities are not well defined.

The Russian or *Siberian* fowls are called excellent layers. They are of a very grotesque appearance, having feathers resembling the beard of a Jew, and quills or feathers on their legs. But little is known of them in this country, and being scarce they are difficult to obtain.

As to food in Maine, we believe that roots will be the cheapest, such as potatoes and carrots, using some pumpkins with them, and while hot, after boiling, stir in meal and bran. When grain is plenty, it is most convenient to use that as the principal food, especially in cold weather. In some large poultry establishments in Europe, roots are the principal food.

We have heard and known several cases of keeping many fowls together, say several hundred, and almost invariably failures have taken place from the fowls being sick, or not laying enough to pay expenses. Whether the want of success has been owing to mismanagement, or to evils that naturally result from large flocks, we cannot tell. We should think it advisable in case of keeping large numbers, to divide them into flocks of about 50, or less, each. It may answer to have 100 in a flock, but we think they will not do so well as a smaller number.

Reward of Industry.——The Eufaula (Alabama) "Shield," of the 1st instant, says:—We were shown on Saturday last, a beautiful set of Silver Castors, which were awarded by the Apalachicola Chamber of Commerce to Col. A. McDonald, of this place, for the best lot of cotton of twenty bales, sold in that city during the last season. The castors are plain and neat, costing $101 in the city of New-York. Thus has the worthy Colonel been rewarded for his industry and skill—and as an inducement to others to direct their attention more to the quality than the quantity of their cotton, we will state that Col. McDonald's premium cotton commanded, when sold, at least two cents more than the highest market price for good cotton. For his present crop nine cents have been offered in the city of New York and refused. Had every planter in the cotton-growing region, pursued Col McDonald's plan of raising cotton, no one can begin to estimate the advantages the country would now be reaping. When will the people learn wisdom?

Sore Backs or Galls on Horses.—Rub white lead in sweet oil until a good paint is made, and apply a coating of this to the injured place. Milk will do where no oil is to be had. It is one of the most effective applications.—Some for the same difficulty use a solution of vitriol in water; but, in most cases, the white lead is preferable.—*Far. Cabinet.*

Horticultural Outline.

AN OUTLINE of the first principles of HORTICULTURE, by JOHN LINDLEY, F R S. &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.—[CONTINUED]

III.—STEM.

57. The stem is that part of the plant which is developed above-ground, and which took an upward direction at the period of generation.

58. It consists of a woody axis, covered by bark having stomata (131) on this surface, bearing leaves, with leaf-buds in their axillæ, and producing flowers and fruit.

59. The points where leaves are borne are called *Nodi;* the spaces between the leaves *Internodia.*

60. The more erect a stem grows, the more vigorous it is; and the more it deviates from this direction to a horizontal or pendulous position, the less is it vigorous.

61. Some stems are developed under ground, such as the Tubers of the Potatoe and the Cormus of the Crocus; but they are known from roots by the presence of leaves, and regular leaf-buds upon their surface.

62. Stems increase in diameter in two ways:

63. Either by the addition of new matter to the outside of the wood and the inside of the bark, when they are *Exogenous;* ex. Oak;

64. Or by the addition of new matter to their inside, when they are *Endogenus;* ex. Cane.

65. In Exogenous stems, the central portion, which is harder and darker than that at the circumference, is called *Heart-wood;* while the exterior, which is softer and lighter, is called *Alburnum,* or *Sap-wood.*

66. The inside of the bark of such stems has also the technical name of *Liber.*

67. The Heart-wood was, when young, Alburnum, and afterwards changed its nature, by becoming the receptacle of certain secretions peculiar to the species.

68. Hence the greater durability of Heart-wood than of Sapwood. While the latter is newly formed, empty tissue, almost as perishable as bark itself, the former is protected against destruction by the introduction of secretions that become solid matter, which is often insoluble in water, and never permeable to air.

69. The secretions by which Heart-wood is solidified are prepared in the leaves, whence they are sent downwards through the bark, and from the bark communicated to the central part of the stem.

70. The channels through which this communication takes place, are called *Medullary Rays* or *Silver grain.*

71. Medullary rays are plates of cellular tissue, in a very compressed state, passing from the pith to the bark.

72. The wood itself is composed of tubes consisting of woody fibre and vascular tissue, imbedded longitudinally in cellular substance.

73. This cellular substance only developes itself horizontally; and it is to it that the peculiar character of different kinds of wood is chiefly due.

74. For this reason the wood of the stock of a grafted plant will never become like that of its scion, although, as will be hereafter seen, (IV,) the woody matter of the stock must all originate in the scion.

75. The stem of an exogenous plant may therefore be compared to a piece of linen, of which the weft is composed of cellular tissue, and the warp of fibrous and vascular tissue.

76 In the spring and autumn a viscid substance is secreted between the wood and the liber, called the *Cambium.*

77. This Cambium appears to be the matter out of which the cellular horizontal substance of the stem is organized.

78. In Indigenous stems, the portion at the circumference is harder than that in the centre; and there is no separate bark.

79. Their stems consist of bundles of woody matter, imbedded in cellular tissue, and composed of vascular tissue surrounded by woody fibre.

80. The stem is not only the depository of the peculiar secretions of species, (67,) but this is also the medium through which the sap flows in its passage from the roots in the leaves.

81. In Exogenous stems, (63,) it certainly rises through the alburnum, and descends through the bark.

82. In Endogenous stems, (64,) it probably rises through the bundles of wood, and descends through the cellular substance; but this is uncertain.

83. Stems have the power of propagating an individual only by their Leaf-buds. If destitute of Leaf-buds, they have no power of multiplication, except fortuitously.

IV.—LEAF-BUDS.

84. Leaf-buds are rudiments of branches enclosed within scales, which are imperfectly formed leaves.

85. All the leaf-buds upon the same branch are constitutionally and anatomically the same.

86. They are of two kinds, viz: *regular* or *normal,* and *adventitious* or *latent,* (119.)

87. Regular leaf-buds are formed at the axillæ of Leaves.

88. They are organs capable of propagating the individual from which they originate.

89. They are at first nourished by the fluid lying in the pith, but finally establish for themselves a communication with the soil by the woody matter which they send downwards.

90. Their force of development will be in proportion to their nourishment; and, consequently, when it is wished to procure a young shoot of unusual vigor, all other shoots in the vicinity are prevented growing, so as to accumulate for one shoot only, all the food that would otherwise have been consumed by several.

91. Cutting back to a few eyes is an operation in pruning, to produce the same effect by directing the sap, as it ascends, into two or three buds only, instead of allowing it to expend itself upon all the others which are cut away.

92. When leaf-buds grow, they develope in three directions; the one horizontal, the other upward, and the third downward.

93. The horizontal development is confined to the cellular system of the bark, pith, and medullary rays.

94. The upward and downward developments are confined to the woody fibre and vascular tissue.

95. In this respect they resemble seed; from which they differ physiologically in propagating the individual, while seed can only propagate the species.

96. When they disarticulate from the stem that bears them, they are called *bulbs.*

97. In some plants, a bud, when separated from its stem, will grow and form a new plant if placed in circumstances favorable to the preservation of its vital powers.

98. But this property seems confined to plants having a firm, woody, perennial stem.

99. Such buds, when detached from their parent stem, send roots downwards and a stem upwards.

100. But if the buds are not separated from the plant to which they belong, the matter they send downwards becomes wood and liber, (56,) and the stems they send upwards become branches Hence it is said that wood and liber are formed by the roots of leaf-buds.

101. If no leaf-buds are called into action, there will be no addition of wood; and consequently the destruction or absence of leaf-buds is accompanied by the absence of wood; as is proved by a shoot, the upper buds of which are destroyed and the lower allowed to develope. The lower part of the shoot will increase in diameter: the upper will remain of its original dimensions.

102. The quantity of wood, therefore, depends upon the quantity of the leaf-buds that develope.

103. It is of the greatest importance to bear this in mind in pruning timber trees: for excessive pruning must necessarily be injurious to the quantity of produce.

104. If a cutting with a leaf-bud on it be placed in circumstances fitted to the development of the latter, it will grow and become a new plant.

105. If this happens when the cutting is inserted in the earth, the new plant is said by gardeners, *to be upon its own bottom.*

106. But if it happens when the cutting is applied to the dissevered end of another individual, called *a stock,* the roots are insinuated into the tissue of the stock, and a plant is said to *be grafted,* the cutting being called a *scion.*

107. There is, therefore, little difference between cuttings and scions, except that the former root into the earth, the latter into another plant.

108. But if a cutting of the same plant without a leaf-bud upon it be placed in the same circumstances, it will not grow but will die

109. Unless its vital powers are sufficient to enable it to develope an adventitious leaf-bud, (119.)

110. A leaf-bud separated from the stem, will also become a new individual, if its vital energy is sufficiently powerful.

111. And this, whether it is planted in earth, into which it roots, like a cutting, or in a new individual, to which it adheres and grows like a scion. In the former case it is called *an eye;* in the latter, *a bud.*

112. Every leaf-bud has, therefore, its own distinct system of life, and of growth.

113. And as all the leaf-buds of an individual are exactly alike, it follows that a plant is a collection of a great number of distinct identical systems of life, and consequently a compound individual.

114. Regular leaf-buds being generated in the axillæ of the leaves, it is there that they are always to be sought.

115. And if they cannot be discovered by ocular inspections, it may nevertheless be always inferred with confidence that they exist in such situations, and may possibly be called from their dormant state into life.

116. Hence, wherever the scar of a leaf or the remains of a leaf can be discovered, there it is to be understood that the rudiments exist of a system of life which may be, by favorable circumstances, called into action.

117. Hence, all parts upon which leaves have ever grown may be made use of for purposes of propagation.

118. From these consideratione it appears that the most direct analogy between the animal and vegetable kingdom is with the Polypus of the former.

119. Adventitious leaf-buds, are in all respects like regular leaf-buds, except that they are not formed at the axillæ of leaves but develope occasionally from all and any parts of a plant.

120. They are occasionally produced by roots; by solid wood, or even by leaves and flowers.

121. Hence roots, solid wood, or even leaves and flowers may be used as means of propagation.

122. But as the development of adventitious buds is extremely uncertain, such means of propagation can never be calculated on; and form no part of the *science* of cultivation.

123. The cause for the formation of adventitious leaf-buds is unknown.

124. From certain experiments it appears that they may be generated by sap in a state of great accumulation and activity.

125. Consequently, whatever tends to the accumulation of sap in an active state may be expected to be conducive to the formation of adventitious leaf-buds. *[To be continued.]*

AN ACRE.—An acre of land contains—4 roods, (or quarters,) each containing 40 poles or perches or rods; 160 rods, 16½ feet each way; 4,840 square yards of 9 feet each; 43,560 square feet, of 144 inches each; 174,240 squares of 6 inches each, each containing 36 inches; 6,272,640 inches, or squares of one inch each.

STUMP LIFTER.—What is the best kind of machine for taking out stumps? Many contrivances have been got up for the purpose of clearing fields of stumps. One of the most common in this section is the wheel and axis, mounted on high posts so as to lift the stumps up. The Albany Cultivator has a cut of one which it says cost $300 or $400, and which has cost the inventor, first and last, $10,000, to bring to perfection. This appears to be an excellent machine, but although it requires but a single horse to pull up a stump of the largest rate, yet it costs too much for "these diggins."

We have seen the following very simple plan of stump clearing, adopted with good success.

Take a strong, stiff, hard wood stick of timber, say fifteen or twenty feet long and six inches in diameter. Cut around the stump and take off some of the roots. Then place the timber upright against the stump, and chain them together strong. From the upper end, which is now in the air, let the chain pass to the axletree of a pair of cart wheels, to the tongue of which a pair of strong oxen are attached. When all is ready, start the oxen along, and the stump "*keels over*" as easy as you capsize a cabbage in a garden.—*Maine Farmer.*

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., MAY, 1845. No. 5.

Mode of Cultivating Tobacco in the Island of Cuba.

Your nurseries are the first to be attended to, in your preparation for a crop, by selecting at the proper season a rich and tolerably moist piece of new ground, and prepare it by burning it off very clean, and breaking it up. The seed is then to be sown broadcast upon it, and when they are up, they are to be overlooked daily, to see that the cut-worm does not commit ravages among the young plants; and as fast as the plants arrive at a proper size, they are to be transferred to the Tobacco field, to make room for the smaller plants of the nursery. As casualties frequently arise to destroy some of the nurseries, it is necessary to guard against a probability of not having a sufficient number of plants, by making three or four nurseries, at an interval of one or two weeks each. Much attention should be observed to keep both your nurseries and field very clean, particularly of grass, and for that reason new lands are preferred for both. In Cuba, they plant on an even surface, and disturb it as little as possible with the hoe, only picking out the grass or weeds which spring up. The plants, when transferred to the field, are to be planted in squares, at about from two to three feet apart, according to the strength of the land. The high lands in Cuba are such as produce the quality of Tobacco, both as to strength and color, that suits the American market best, and such lands correspond nearest to our high hammocks. The greatest enemy to the plants, both in the nursery and in the fields, (while small,) is the cut-worm, which has to be looked after early every morning, and wherever they have eaten the plants, they are to be found and killed, either on the plant or on the ground near it. When the plants get to be larger, then the large green Tobacco-worm is to be constantly guarded against, and the suckers also continually broken off as fast as they appear, and when the Tobacco is judged to be of a sufficient height, it is to be topped and allowed to mature for cutting. The time of maturity is ascertained by the leaves changing gradually their color, beginning at the bottom leaves, from their deep green growing color, to a yellowish green; but if this is not sufficiently obvious, and you deem your Tobacco ripe, you may test it by crushing together the tip of any of the upper leaves, which, if it snaps, is a sign of its being ripe; but on the contrary, if it does not snap, it is not fully matured. When ripe for the knife, it is cut down near the ground, leaving two suckers, which have been spared a week or two prior, ready to grow up and produce a second crop, and also a third crop may be realized in the same manner. The Tobacco is to be conveyed carefully in wide thongs of cowhide to the house, to be hung up; a shed is preferred, with free space for ventilation beneath, and after tying the plants together, two to each string, and leaving space enough between them to insert a wooden peg, you hang them up, by intruding them above each rafter up to the ridge of the house, being careful not to hang them so near that they will touch or crowd each other in drying, or your Tobacco will mould. Also when the weather is moist, you must make small fires enough under it, to keep out the moisture, but not enough to heat your Tobacco. When the leaves are perfectly dry, the whole are to be taken down, and placed in a press for a few hours, the object of which is, if the Tobacco is too dry to strip off without breaking the leaves, that they may become soft and pliable, but great care must be taken that it does not heat, and it must be strictly examined, by inserting the hand to ascertain that it becomes not too hot. The press is made by putting rails or poles crosswise of each other, in form of a rack, and placing cow-hides under, over and around the Tobacco, and placing upon it something somewhat weighty. It is then to be stripped leaf by leaf from the stock, and being selected, the wrappers from the fillers, to be tied at the butts, and prepared for market. It is sometimes usual to put it again in press after being stripped.—*Floridian.*

Tanning on the Plantation.

Tanning leather, for the use of the plantation, is an item of good management that should not be overlooked by any planter. Nor would it be as much overlooked as it is, if the simplicity of the process was generally known—that process, I mean, that will suffice for making leather for home use. The *tanner* by profession, in order to prepare an article that will command a good price in market, and have a merchantable appearance, puts the hides and skins through a greater number of manipulations; and, that he may work to better advantage, has his arrangements on a more extensive scale.

The vats, tools, and implements really needed, are few and simple. Four *vats* will generally be found all-sufficient; one for a *pool* of fresh water, and for *baiting;* one for *liming;* another for *coloring;* and a fourth for *tanning*. The best size, in the clear, is seven feet long, four and a half feet wide, and five feet deep. They should be placed so as to be easily and conveniently filled with water from a spring, running stream or cistern. Dig the holes 9 feet, by 6½ and 6; if the foundation is clay, the depth need not be over 5 feet. Form a stiff bed of *clay mortar* in the bottom, on which to lay the floor, and on it erect the sides and ends of the vat, of plank of almost any kind, sufficiently thick to resist the pressure from without—two inches will be thick enough. When this is done, and the whole nailed fast, fill in the vacant space round with *well-tempered* clay mortar, ramming it effectually: it is on this, and not the planks, that dependence is placed for rendering the vat perfect. When well made, a vat will be good for a long lifetime—the *ooze* preventing the decay of any but the top round of plank. Such a vat will hold 15 large beef hides (30 sides,) besides a number of small skins.

The material used for tanning, is the bark of the red or black oak, stripped when the sap flows in the spring, stacked and dried—of which, about four pounds are supposed to be necessary to produce one pound of leather. There is an article occasionally used, called "catechu," which is an extract made from the wood of a mimosa-tree, a native of India, half a pound of which answers the same purpose. Galls, willow bark, the bark of the Spanish chesnut, and common elm, as also sumach, are all used by the tanner. It has been recently found that the root of the palmetto answers an equally good purpose with the best oak bark.

Bark has to be ground as wanted; or if the quantity needed is small, and it is not thought advisable to incur the expense of a *bark-mill* (from $10 to $18,) it may be pounded in a large mortar, or beat up on a block. It will require one third more of *pounded* than of *ground* bark, to afford equally strong *ooze*, which is the infusion of bark.

The principal tools requisite, are a *fleshing-knife, currier's knife*, a *brush* like a stiff horse-brush, and a *fleshing-beam*. The fleshing-beam is made by splitting in two a hard-wood stick of about a foot in diameter; inserting two stout legs, some thirty inches long, in one end of the split side, so that the other end rests on the ground, with the round side up, the elevated end being high enough to reach the workman's waist. A fleshing-knife may be made by bending an old draw-knife to suit the *round* of the fleshing-beam.

The skins of bulls, oxen, cows, and horses, are called *hides;* those of calves, deer, sheep, &c., are known as *skins*.

Fresh and *dried* hides receive the same treatment, except in the washing process. Those that are salted and dry (and no hide should be dried with less than from two to four quarts of salt being rubbed on the flesh side—dried without salt, it is extremely difficult to soften them,) require to be steeped, beaten, and rubbed, several times alternately, to bring them to a condition sufficiently soft for tanning.

Green or fresh hides must be soaked in pure water from 12 to 24 hours, to extract all the blood, &c., and soften the extraneous fleshy matter, which must then be removed—throwing one hide at a time on the fleshing-beam, *grain* or hair-side down, and scraping or shaving off with the fleshing-knife, which must be somewhat dull, or the skin is apt to be cut. They are then put in the *liming-vat*, which is supplied with strong lime-water, by filling the vat a little over half full of water, and adding thereto four bushels of unslaked (or of air-slaked) lime, or at the rate of two-thirds of a bushel of lime to the barrel of water. This will suffice for fifteen hides; each time that they are removed and a fresh lot of hides put in, add another bushel of lime, which will keep up the strength for a twelve month. Before using, stir the lime well up, and while it is thus mixed with the water, put in the hides evenly, so that the lime will settle on every part of them. They are to remain here from ten to fifteen days, or for three or four days after the hair will rub off with the finger completely and with ease. While in the liming-vat, they must be moved up and down every other morning, to expose them to the air, and to the equal action of the lime. Being now ready for unhairing, cut each hide in two, by slitting them along the centre of the back with a knife, forming them into *sides*. Throw ten or twelve of these sides on the fleshing-beam, and strip the hair off with the knife; and as they are unhaired, throw each one into the vat of fresh water to bait or soak. When the lot of sides and skins in hand have been all unhaired and thoroughly washed, throw them again, and at once, on the fleshing-beam, with the *grain* or hair side up, and *wash them over* (rub and press them) with the knife until all the gummy or mucilaginous matter is worked out. This should be repeated two or three times during ten or twelve days, being each time baited anew in fresh water. And this *working over* must only be done when the sides feel soft and smooth to the touch; as they will at times, from some unexplained cause, feel rough, at which time they must not be *worked over*. While they are thus *baiting*, they must not be neglected, or they will soon spoil. Tanners are in the practice of adding 1000th part of sulphuric acid (oil of vitriol) to the last *bait*, which has the effect of swelling the pores and distending the fibres, and thus rendering the skins more susceptible to the action of the ooze: forty-eight hours generally suffice for this last *baiting*.

In the meantime, some good strong *ooze* should be prepared for the first *tanning* process, called *coloring*. Fill a vat a little more than half full of water, and add bark, in the proportion of one and a half bushels of *ground*, or two bushels of *pounded* bark, to the barrel of water, which will bring the vat up to about two thirds full. When the bark has soaked from four to five days, the sides are put in, and allowed to remain fifteen days; during which they must be *once* well and carefully *fleshed* and *worked over*, and must be drawn up and down every morning, for the first week at least, and the bark well *plunged* or stirred up, to have them *color* evenly.

After this, the vat being now two thirds full of this same *ooze*, after drawing out the hides, lay a

good coating of fresh bark, of say an inch thick, on the top of the water, on which it will float; lay on this a side, spread out evenly; and if it has to be lapped over in any part, lay on more bark until it is all well coated, taking care to place those at the bottom of the vat now, that were at the top last time. On this side lay an inch coating of bark, and on that another side, and so on, with alternate layers of bark, until the vat is full, or the sides all laid away.

In this, which is called the *first bark*, the sides must lie four weeks. They are then drawn out, and the spent-bark, taken out with a *skimmer* or *drainer*. The sides are then replaced as before, with alternate layers of fresh bark, in the same ooze, which has acquired some additional strength, notwithstanding the amount of tanning and extractive matter contained in the bark, that has become intimately combined with the animal fibre of the hide. In this *second bark* they remain six weeks undisturbed, when they receive a *third bark*, in the same way, in which they are left another six or eight weeks. Three *barks* will suffice to tan deer, hog, calf, and other small skins; four *barks* will make good sole leather, but five are preferable.

The *tanning* process being completed, *sole* leather is taken out of the vat, rinsed effectually, and dried in the shade, hanging the sides up by two of their corners to joists, where they remain until wanted. Those sides intended for upper and harness leather, (which are those of cows, &c.—the largest and thickest bullock hides being used for sole leather,) as also deer, hog, and other small skins, being thoroughly rinsed, are spread out on a strong table, with the grain or hair side up, and scoured with a stiff brush, like a very stiff horse-brush, occasionally throwing on pure water, until *all the ooze* is scoured out. Tanners use the edge of the stone, made smooth, to assist in rubbing out the ooze, and all the water that can possibly be rubbed out. They also use what they call *a slicker*, being a dull edge of copper of about six or seven inches long, set in a piece of wood, to serve as a handle.

After they are all served thus, and rubbed as dry as possible, the table is cleaned off, and the skins thrown back upon it, *grain side* up, and are rubbed with tanner's oil (cod-fish oil) as long as the leather will receive it. Harness leather must be completely saturated. As they are oiled, fold them up and lay them aside. When they are all gone over, lay one on the table at a time, flesh side up, and with a rag rub on all the *dubbing* that the leather will absorb. Thin hides require but a small quantity; harness leather must have a heavy coating.

Dubbing, which consists of equal parts of tar and tallow, melted together, and well mixed, must be made the day previous to being used. Lard *may* be used in place of tallow, but will require a lesser proportion of it. Each side of leather is then hung up by two corners to joints, there to remain until perfectly dry, or until wanted. If iron or steel touches a hide during the process of tanning, when in the least wet, or even moist, it will discolor it, forming an indelible black mark.

To *blacken* harness or other leather, take the skin when completely dried, and if any greasy spots appear, showing that more oil or dubbing has been applied than the leather could absorb, wet the spots with a little strong ooze, and scrub them out with a brush. Then apply a good coat of *copperas*, (sulphate of iron) dissolved in ooze, until the leather has a good color all over. After this, when dry, put on another good coat of oil. The leather may then be smoothed off with a rounding edge of polished steel, or glass, or stone. T. Affleck.

Ingleside, (Miss.) Sept. 19, 1843.—[*Am. Agr.*

Yellow Locust.—If you have but little fencing timber fit for posts on your farm, sow a few pounds of yellow locust seed, and when the plants are two years old they may be transplanted. In twelve years from the time the seed is sown you may begin to cut them for posts. Say you, twelve years is a long time to wait; but you should recollect, that every farmer has some spot where they might be grown, and that, as fencing is a dear article, every farmer should endeavor to grow his own timber.

In Setting Trees, do not place them deep, and let the earth around them remain concave that it may catch the water.

Corn-Stalk Sugar.

To Col. A. G. Summer, Editor South Carolinian:—

Dear Sir—When I saw you last, you asked me for some directions for cultivating Corn-stalks and making Sugar. I transcribe you an article, containing much useful information on the subject, from the Saturday Courier, published in Philadelphia. I now take pleasure in complying with my promise, to furnish you with my own experience.

DIRECTIONS FOR CULTIVATING THE CORN-STALKS, AND MAKING SUGAR.

"In various portions of the country, the cultivation of Corn for the manufacture of Sugar, continues to excite attention. The public are seeking information upon the subject, as the discovery that Sugar can be made from the stalks of Corn, is of recent date. We take pleasure in presenting our readers any facts that may be of importance, upon the subject. Dr. Naudain, of Delaware, who has had opportunities to gather knowledge upon the various experiments that have been made, presents some views which will not fail to be regarded with interest.

"With regard to the culture, it is stated that Corn should be planted as Broom-corn is commonly planted, very close in the row, probably a stalk every three or four inches. The tillage will be the same as for Broom-corn. When the young ears begin to appear, it is necessary to pluck them off carefully, and to repeat the gathering as often as necessary, so as *to prevent the formation of any grain*. Because, if grain be allowed to form, it takes all the Sugar from the stalk. About the time the corn begins to harden, the making of Sugar should be begun.

"It is not necessary to say anything about a proper mill to crush the stalks and separate the juice, because mills of the cheapest kinds only should be employed now, until the business would fully warrant an expensive outlay. It would probably be found that the common cider mill, with plain cylindrical nuts, would be quite sufficient for the farmer who would raise a fourth or half an acre of Corn for Sugar, for his family, and this quantity would be quite sufficient for satisfactory experiment.

"When the juice is separated from the stalk, about a tablespoon full of whitewash, made of the *best quick lime*, and about the consistence of thick cream, should be added to each gallon of the juice, and then the boiling should commence. The scum that rises should be carefully removed; and the juice, if this process has been properly conducted, will be quite clear, nearly colorless. Then commences the process of evaporation; and when the juice has boiled down in about the proportion of eight gallons to one, the boiling will be completed, and it may be poured out into a shallow, tight wooden box to grain.

"It has been ascertained, although as yet the reason is not known, that if the juice be boiled in a deep vessel, like the common cooking vessel, Sugar will seldom be obtained; while, if it be done in a shallow vessel, so that the juice at the commencement of the boiling shall not be more than three to five inches deep, Sugar would be obtained without difficulty. It has been ascertained, also, that the Sugar from Corn will not grain so readily as that from the Sugar-cane; and in some instances, it has remained more than a week after the boiling, before the Sugar was formed, and yet excellent Sugar was made.

"It should be particularly remembered, that the juice should be boiled as soon as separated from the stalk. It becomes acid very soon, and no Sugar can be made if the juice be allowed to stand two or three hours before it is boiled. The juice will even spoil in the stalk before it is ground, if the stalks be cut off a few hours before grinding. It is necessary, then, that every part of the process should be done with the greatest despatch. The stalks should be brought to the mill as soon as cut, and ground immediately. The vessel for boiling ought to be properly filled in two hours grinding, and the process of boiling down should immediately commence, and be continued until completed.

"Excellent Syrup, superior to the best Molasses, will be obtained by observing the above directions, and boiling five gallons of juice to one gallon.

"The juice of the Corn-stalk is very rich in Sugar, when cultivated in the manner suggested. Tested by Beaume's Sacharometer, the instrument used to measure the strength of syrups, the juice of the Corn-stalk weighs 10 to 10½ degrees, which is about the weight of the best cane in the West Indies, and is richer than the juice of the cane in Louisiana, which is seldom heavier than 8½ degrees.

"One gallon of juice will produce nearly 1½ pounds of Sugar; and one acre of good Corn will yield, if carefully expressed, from 700 to 1000 gallons of juice."

I have but little information to add to the above article. My kettle holds eighty gallons, though a sixty gallon kettle might answer the purpose, but probably it would be best to procure a shallow vessel, as above recommended for making Sugar. I made three boilings before I made good syrup, not boiling down sufficiently the two first boilings. Prepare yourself with a skimmer, a gourd with a long handle will do to remove the scum when it begins to boil, and for a short time after. Leave off skimming when you see the dark glutinous scum is pretty well removed. Also, prepare yourself with an iron ladle, with an iron handle attached to it about three feet long, (which any blacksmith can make,) perforated with small holes. Whoever attends the kettle must use this ladle, in raising the juice with it, when likely to boil over. When the juice boils down considerably, you will see the bubbles begin to show and burst on the surface. When you see a few such bubbles, if it be your object to make syrup, I think then is the time to take it out; but if you wish the syrup to granulate, boil till the bubbles become general on the surface. You can also test it, by dipping out some syrup with a tablespoon, and when it cools sufficiently, by taking it between your thumb and fore finger; and if it inclines to rope, it is syrup, but if it will rope about an inch it will granulate. You can boil rapidly at the commencement while the juice is thin, but as it thickens boil with more moderation. If you boil too rapidly after the bubbles begin to burst on the surface, you will certainly burn it, and it will give it a candy taste. If you cannot get lime conveniently, lye will answer the purpose. I should say, put in about a half a pint of lye to every fifteen gallons of juice. Throw in the lye or whitewash made from the lime, immediately after you quit removing the glutinous scum. When you have boiled to satisfy yourself, take out the syrup and put it in some shallow vessel to cool. I am inclined to think, when the juice has been extracted from the stalks by a wood mill, that if they were chopped up and boiled in water, good vinegar could be made from them. I advise you to build a wood mill. The expense is trifling. You can get a mechanic in my neighborhood, who will build you one for twenty dollars, by furnishing him two assistant hands; otherwise, send over a common mechanic, and after looking at mine, which is a good model, you can have one made at home. I advise you to plant your Corn for experiment in bottom land (if not rich, make it rich by improvement) in drills, from four to six inches in the drill, and the drills from thirty to thirty-six inches wide. Now, sir, I close my crude directions, by wishing that you may win in this race, and that we may all win, and that another article of general consumption may be added to the products of South Carolina.

Yours respectfully, James S. Pope.

Island Ford, Edgefield Dist., S. C., Feb. 1845.

☞ *We* sow half a bushel of corn (cost 33 cents) on two acres planted with corn—on the surface. We thus coax the birds to come and see us, and we make it their interest to meddle with nothing that is planted. It costs us less than twine, or tar, or feathers on a pole.—*Plow.*

Butter.—Difficulty in Churning.

Mr. Cabinet—Please to ask your folks, instead of writing so many things which we know already—and some we don't want to know—to turn their attention to the department of *female husbandry*, and instruct us a little in that.

In the days of our grand-dames—as many a legend tells us—when witches were almost as numerous as cats, and quite as mischievous, riding broomsticks on their errands of mischief, the good housewife frequently encountered the greatest difficulty from their malicious interference with her household affairs; unless her stable door and "that dear cot her home," were protected by the potent charm of an old horse-shoe, the horses' manes and tails would be twisted into *cues;* the cows would either be sucked dry, or their milk turned to blood, or when churned would not make butter; her vinegar would not stay in the barrel, nor her soap in the tub, nor could she even supply its loss, unless she used the precaution to stir the soap pot with a *sassafras* stick, *top down*. In those perilous times, stern necessity devised many means to break the spell, to burn the witch, or to douse her into scalding water. But to us who are young, this is mere matter of history—fabulous history it would seem—for no sooner did the people cease their efforts to *keep the witches out*, than they made the discovery that there were none to *get in*. Oh, pshaw! I sat down to inquire about churning, and here is a homily on witchcraft.

It is a fact unfortunately too well known, that in small dairies of one or two cows, perhaps cows which have been milked for several months, there is often much difficulty experienced in churning the cream into butter, especially in cold weather—sometimes the cream is converted into a thick froth, and will not *break;* at other times, the butter forms into small pellets resembling fish eggs, and will not *gather*. Now it is no trifle to have all the trouble and labor of gathering the cream, and churning a whole day, perhaps two or three of them, and have to eat your buckwheat cakes without butter at last. Formerly it was only necessary to expel the witch, and all was right; but now-a-days, there is no witch, and we don't know what to do.

One thinks her cow is too poor to churn for and exchanges her for one no better. Another can't get butter because her cows are fed on turnips or pumpkins. A third condems oats' straw as feed for cows, and who would not agree with her in that; and some think that even the oats themselves, ground either alone, or with corn, make inferior butter or none at all.

Now, all this may or may not be so. We think there is some difference in cows, and in cow-feed too; for we see a great difference between the milk of different cows, and of the same cows under different keeping. Still, as the complaint seems only to prevail in winter, we think that winter may have something to do with it, especially as our own cream will churn readily one week, and hardly at all another, cows and food the same.

Now, what do your Cabinet folks say to this? you often talk about chemistry. Now can't you tell us what is the chemical process of converting cream into butter, what constitutes the difference between the two; and what are the essential conditions necessary to effect the change? Do tell us where the cream-pot should be kept in cold weather? How it should be stirred and managed? What put into it? How the churn should be prepared, &c. &c.

Do tell us all about it, and oblige a whole heap of Young Wives.

[It would afford the editor no small gratification, if he were able to remove a difficulty, which has from time immemorial, for aught we know, perplexed and annoyed, not only "heaps of Young Wives," but also any quantity of *old* ones, who had thought that in most matters they had cut their wisdom teeth. We must, however, leave this to wiser people, and hope some of our readers will be able to render assistance in the premises. There is an excellent article under the head of *Butter*, in the Farmer's Encyclopedia, which is too long for the Cabinet, and to which we can only refer. We can very well sympathise with those who are worried in this way, having many a time watched with no little chagrin, the prolonged and fruitless labors at the churn, for six or eight, or even twelve hours: and then, after all, if the *buckwheat cakes* were not eaten *dry*, they might as well have been, for the stuff that was produced when the butter did *come*, it indeed it came at all, was not worthy of the name of butter, and hardly that of decent *grease*. Perhaps there is no better plan for having butter in winter, and little difficulty in the churning of it, than to feed the cows well with Indian meal and green food, as carrots, turnips, potatoes, &c., and to keep the milk or cream at a moderate temperature. A friend in Jersey, and by the way, an excellent house-keeper, remarked to us a few weeks ago, that she kept her milk and cream, during the winter, altogether in a closet in the kitchen: thus, at a constant temperature, from 55° to 65°, it readily soured, and she had no difficulty in *getting* her butter; and the quality of it, when she does *get* it, ourselves are particularly fond of testing. This plan of keeping the milk warm, is, we believe, practised to a very considerable extent, by our large and nice dairy people on this side the Delaware.—*Ed. Far. Cabinet.*]

[The following is from the Ohio Cultivator, recently established by Mr. Bateham, formerly proprietor of the Genesee Farmer. He seems to be mightily tickled with having got two *lady* contributors to his columns, and well he may be, since few of his brother editors are so fortunate as to get *one*. He prefaces "Emily's" contribution with the following remarks, the *spirit* of which is imputable to the fact that the writer is (fortunately or unfortunately?) a *single* man, though *doubly blessed* with female correspondents.—*N. E. Farmer.*]

"*The Campbells are Coming!*"—Stand aside, gentlemen! front seats always reserved for the ladies! We felt quite sure that we should have the assistance of the ladies in our enterprise, and, sure enough, here it comes! 'Tis true, they are naturally a little coy at first, and need some *coaxing;* but when they *do* become enlisted in a good cause, it is sure to go ahead. We have, therefore, no longer any fears about the success of our undertaking. The Ohio Cultivator will not only be sustained, but eminently successful in accomplishing the great object for which it is designed.

We have received two communications from female contributors, both of them of a plain, practical character, aiming at utility rather than amusement. The first is from a farmer's daughter, and we think will be useful to many of her sex at the present time:

BUCKEYE MODE OF MAKING BUTTER.

Mr. Editor—Having read in the second number of your truly valuable paper, that no one had contributed for the department which you are so kind as to appropriate to the use of ladies, I feel inclined to put in my mite, small as it is, in the hope that it will encourage others of my sex, for I think it is a pity that they should neglect so good an opportunity for exercising their talents, and "showing their quality."

My object in writing is, to inform your readers that I have derived much assistance in the performance of my duties as a farmer's daughter, from reading agricultural papers. My father has taken the Genesee Farmer for several years, and I have found much instruction in its columns that has been of advantage to me: one instance of this kind I will relate.

I have for several years had the entire care of the milk department in my father's family. I therefore read, with great interest, whatever related to making butter and cheese, and I found much that was different from what I had been in the habit of practicing. One case of this kind was, directions for making butter in winter, according to what is called the Russian method, by which it was said butter could be made in winter as sweet, and with as little churning, as in summer. So I set about trying the experiment, and the result exceeded my expectations. My new practice is as follows:

Before I go out to milk, I put a kettle, say one-third full of water, and large enough to let the milk pail into it, on to the stove, where it will get boiling hot by the time I have come in with the milk. I then strain the milk into another vessel, and wash the pail, (which should always be of tin,) then pour the milk back into the pail, and set into the kettle of boiling water till the milk becomes scalding hot, taking care not to let it boil, then pour it into crocks or pans, and set it away in the cellar for the cream to rise in the usual way. As little time should be occupied in this heating process as possible: hence the advantage of having the water ready hot when the milk is brought in.

Cream procured in this way, will seldom require more than twenty minutes churning, while by the common practice, the poor dairy-maid may have to churn for hours, and then, perhaps, have to throw it away, as I did myself on two occasions, before I happened to gain this valuable piece of information.

Respectfully, &c. Emily.

P. S.—(A lady always adds a postscript.) I forgot to say, that if you get a "Buckeye" wife, and she makes butter for you in winter according to this method, you will find it but little inferior to that made in summer. E.

Kindness to Animals.

The following, which we copy from the Massachusetts Ploughman, we commend to the special reading of every one who has charge of beasts of burthen. The example of the owner of the runaway oxen alluded to, cannot be too generally followed. If kindness, instead of the brutal treatment usually meted out to dumb beasts by their drivers, were resorted to, we have no doubt that many of the faults and tricks to which they are subjected might be overcome.

Mr. Editor—In passing through the town of S——, a few days since, I stopped at the residence of a distinguished farmer of that town; it so happened during my short stay, his steers which he was working at the time, by some means, escaped him and ranaway. After much running and trouble, they were overtaken and brought back, which done, the good man very deliberately and good naturedly stepped into his corn barn and brought out several clever ears of corn and gave them to eat; at the same time patting them on the sides, saying, "There *Buck* and *Bright*, take *that* and *that*, and know better than to run away from me again." The steers seemed to forget their skittishness at once, and became tame and familiar. They indicated as much as to say, "Master, we were afraid, wherefore, we ran away; but now, we believe thee to be our friend, and shall no more fly from thee."

There, thought I, is a lesson of moderation and kindheartedness worthy the regard of all those who have the care and management of dumb beasts. And it is here *noted* for the special consideration and behoof of all such as are in the constant habit of maltreating their domestic animals. What a contrast this to the manner of some, who, instead of forbearance and kind dealing, upon every occasion of waywardness in their horse or ox, fly at him, cudgel in hand, and deal "death and damnation on his defenceless head like a very Turk!" How many noble animals have had their courage broken down and rendered spiritless by such brutal treatment—it is worse than *brutal*, for no brute animal will treat his fellow so unnaturally! How many colts and steers have been thus spoiled in training to service! "The merciful man is merciful to his beast!"

Nor are others less culpable who leave their cattle exposed to the inclemency of winter weather, without shelter, and a sufficient and proper supply of food. Man, take care of thy beast and be kind to him, else his voice may be heard in heaven testifying against thee!

Respectfully, B. F. Wilbur.

From the Mobile (Ala.) Register & Journal.

Indigo.

That a new system of planting must be adopted in the South, is a singularly general opinion. For individuals to discover their errors, is not entirely a common occurrence; but for a whole country to be convinced of an erroneous course, is assuredly singular, and a flattering omen of the probable correction of error. The least informed of our citizens appear to have picked up, within a few months, the solid reasons for a deviation from the track that we have been in for years, and admit the superior good sense of the Northern farmers in their plan of "mixed crops." This, with others, is certainly one of the lessons of practical wisdom, that the depressed state of things has taught our people, for the sheer fact is, this depression has set them to thinking.

The idea of a "full crop" of cotton, grew up with the article, in our planting community, and strange as true, it never was applied to any other production of agriculture throughout our country. Had the same idea got hold of the Northern and Western farmers, as regards the article of hemp, the same result would have followed, and long ere this, that plant would not have been worth raising.

Unfortunately for the South, the idea which we now can view as preposterous in the extreme, has in its result destroyed for the present the possibility of labor directed to the production of the great hitherto staple of the South finding a fair remuneration, and placed the country in the awkward state of embarrassment in which we find it. One assurance, however, of a better state of things, is that unanimity of sentiment and views in the community, as regards an immediate change of our course and the adoption of a wiser one.

A few days ago, I was forcibly struck with the absurdly extravagant inconsistency of the course the country has been pursuing, by observing a domestic incident. On sitting down to dinner, certainly not a sumptuous, but simply a comfortable one, I was astonished to see the number of States and Territories of the Union, with different parts of the habitable globe, that appeared to be called in requisition to provide for it. I saw before me a part of a ham from Westphalia, a middle of bacon from Ohio, a piece of Fulton Market beef, potatoes from Connecticut, with onions from Massachusetts, a pudding, the basis of which was produced in South Carolina, mustard from England, sweet oil from Florence, pepper from the East Indies, sugar from the West Indies, and coffee from Java. The desert, although simple, brought together the North and South—apples from Vermont, and oranges from St. Augustine, etc., and last of all a Bologna sausage, made of no one knows what, but all the way from Italy, consequently, like all other foreign preparations for the gourmand, must be superior. The production of Zerez in the way of liquid, and a little of France, in the form of cogniac, settled the account.

I confess I was left after a heavy dinner with the reflection that the *rationale* of all this could not be laid down, and as soon as possible I quit reflecting on the subject.

My last paper suggested to the planting interest the addition to their crops of INDIGO. This dye-stuff, it must be recollected, we import annually to a large amount, and this consideration, added to the fact, that no substitute has been found for it, the vast number of fabrics it is necessarily attached to, and the increase of our manufacturing establishments, most certainly offers a rational encouragement to direct our labor to its production. And to other considerations, that the labor required for its production, embraces but a short portion of the year, is light as any other cultivation; and admits attention to other valuable productions of agriculture, and last, but not least, the freight or transportation of this article is almost nominal.

The last consideration to those who notice the expense and the time required in the different transportations necessary to bring the article of cotton to market, will be kept in view and duly appreciated. A large amount in value can be put into a small package, and by keeping in a dry state, this article does not deteriorate with age.

From a communication made by a dyer of no small celebrity in the North, it is evident that we have a superior climate and soils for the production of this dye-stuff, in addition to which the writer of this article had sent to him a sample of cotton fabric, the blue colors of which was given by the production mentioned in a paper heretofore, and which, for a transparent hue, could not be excelled. A future paper will give what may be to some new, and who may not be particularly acquainted with the mode of cultivation, the best soils and most approved mode; also, the process of preparing the coloring matter for market.

SOUTH ALABAMA.

From the New England Farmer.

Necessity of supplying the Soil with the Constituents of the Crops grown on it.

The new light which the improved state of science is throwing on agriculture, must be hailed by all *thinking* farmers with joy. At present this light is restricted in its radiance, but few, comparatively, out of the ranks of the learned, feeling its beneficial influence. But the time seems to be approaching—let us bid it speed—when in the culture of the earth, *science* will guide practice, and good farming, the most profitable farming, become an art which will require the skilful exercise of intelligent MIND, more than the exercise of physical power, to pursue it with the greatest success.

Chemistry, the patron-genius of agriculture, is now lending its aid as it never before lent it, to dispel the darkness which has too long enveloped the farmer in his pursuit, and teaching him to see, and enabling him to comprehend, the true processes by which his crops and animals are formed, and the necessary conditions required to make the one heavy and the other fat, at the least expense and with the most profit. The desirable light is being constantly diffused by scientific men, particularly in England and Scotland, in lectures and communications through the press, and thousands seek it as eagerly as they do their own prosperity, and, indeed, their prosperity depends in an important degree upon it.

To no one, we think, are the farmers on either side of the Atlantic, more deeply indebted for efforts to benefit them by imparting valuable scientific knowledge, than to Professor Johnston, of Scotland. The following abridged report of one of his late lectures before the *Dumfries Farmers' Club*, on the necessity of returning to the soil the constituents of the crops taken off, I think will interest many of your readers:

"The different substances of which plants are composed, must exist in the soil on which they grow: according to the nature of the plant to be reared, so ought the land to be manured. Thus, while wheat grain contained only two per cent. of ashes, hay contained ten per cent. Hence, the wheat required a much larger amount of combustible aliment than hay. It was true that the whole of the combustible matter was not obtained directly from the soil, as a large portion was derived from the air; but from five to ten per cent. of the straw of wheat was obtained from the soil: hence the provision made in leases, that no straw should be carried off the land. Different kinds of hay carry off different quantities of inorganic matter from the soil, and consequently have different effects upon the land.

"Every plant grown, requires, in accordance with the nature and composition of the soil, the proportion of the ingredients in its ashes. If no alteration of crop is made, nature will become exhausted in some of her resources, and the plant for want of requisite nourishment from the soil, must die. We have facts to prove that nature will not forever grow the same plant on the same soil. The Black Forest consisted first of oak, then of pine, and now it is again covered with broad-leaved trees; and as with trees, so with crops; and as on a large, so on a small scale.

"Different modes of husbandry have been adopted. Instead of oats being grown fifteen or twenty years on the same soil, the rotation of three white crops and six years' grass was adopted: this also, has become antiquated, and now the preferable alternation of white and green crop is adopted. Alternating crops, and adding such manures as have been carried off by preceding crops, is the only profitable mode of cultivation, while nature will also assist by the going on of certain circumstances, such as the decomposition of minerals, &c.

"A soil containing just sufficient lime for a luxuriant crop of rye-grass, would be far deficient for either clover or lucerne. The soil must contain in abundance what your crop specially requires, and consequently the necessity of selecting the manure to suit the crop wanted.

"The ground becomes exhausted in many ways. By cropping too long with either one kind or different kinds of grain and straw, it becomes exhausted of some of its soluble matter by the action of the rains, just in proportion to the wetness of the soil. By the application of proper manures, the waste may be replaced. Feeding on the ground will replace a portion of the waste of solid matter, by the dung voided by the animals; but a great portion of the *soluble* is lost, both by being, to a small extent, irrecoverable, and because of the direct waste by carelessness or ignorance. Those soluble or saline substances, are principally contained in the urine of cattle, and just in proportion as it is lost, so is the direct waste. Guano is not a more valuable manure than the urine of cattle. By building suitable tanks, the whole of the barn-yard saline might be preserved, and 900 lbs. of good solid matter, equal to the best Peruvian Guano, would be the annual produce of one cow. We have frequently been astonished at the results of certain saline substances when scattered over unhealthy plants, and by the first shower washed into the soil and immediately consumed by the plant as its proper and necessary food; and just in proportion to the ease with which it gets the substances upon which it is supported, and of which it is composed, will it vegetate and flourish.

"To resume: Suppose any of the substances of which a plant is composed, to be already in the ground in sufficient proportion, then any addition cannot do good. Suppose soda to be in sufficient quantity for hay, any addition would be unprofitable for a rye-grass crop, while it would be of immense benefit to clover or lucerne. And again, some soils contain it in sufficient quantity for every variety of crop, consequently any addition would be unprofitable. Hence the reason of so many conflicting opinions respecting the utility of various manures. One tries gypsum, in whose soil it is deficient, and finds it an invaluable manure; another applies it to his soil, which is already well supplied with it, and pronounces it worthless.

"Milk contains so much bony earth, that in 75 years, a cow pastured on an acre of land, will carry off a ton of bones. Hence, (the Professor said,) some lands used for dairy purposes in Cheshire, had, in the course of years, deteriorated to such a degree that they were not worth more than from 5s. to 10s. per acre, just because the cows pastured on them had carried away all the bone out of the soil. Bone-dust was at length applied as a top dressing, and the results were so astonishing, that the land increased 700 per cent. in value, and the rector's tithes were increased five-fold. Any or all other manures, had the soil wanted bone, would have proved ineffectual. The bones added just what had gradually been taken off in the lapse of years, in consequence of the peculiar husbandry of the district."

FRUIT IN THE FAMILY.—Is it not strange, in a country so capable of producing fruits of almost every kind in abundance, that so few have apples or any other fruit for the winter nights? It is a fact, perhaps not known to all, that fruit constitutes the best desert after dinner, and it is most wholesome for every one. Too often farmers think, they will not live long enough to enjoy the fruit if they were to plant orchards; but they should recollect peaches will bear in two or three years from the bud, apples in three or four, and pears in a little longer time; and even if the older people should not live to enjoy all their labor, they should do something for posterity. Let the aged give a good example to

the young, and the next generation will do better than the present. But little ground is necessary for an orchard, and nothing pays so well for the labor and expenses. Moreover, the farmer who regards appearances, should be ashamed of a place naked, and free from fruit trees. Nothing, indeed, is so ornamental as luxuriant fruit trees loaded with their annual treasures.

From the Tennessee Agriculturist.

Wool.

We have the satisfaction of knowing that our efforts to draw the attention of the farming community of our own immediate region to the important subject of wool growing, is being realized, and that they are awaking to a sense of the vast resources that are presenting themselves through sheep raising, and also of the increasing value of the mountain lands in this State adapted to this purpose.

A few facts connected with the history of other countries, when brought before the notice of the farmers of Tennessee, and indeed of the whole of the Southwestern States, if considered with care, will, we think, induce many of them to revive their system of sheep husbandry, and extend them to their utmost limits.

The growth of wool has never been undertaken by any country or by any people, without returning to that people all the blessings to be enjoyed on this earth, that peace and plenty could bestow. The political situation of Spain may for a time, and no doubt will, operate against that prosperity which she has so long enjoyed through her wool trade; and it is probable that her flocks may comparatively degenerate, through the anarchy and confusion that reigns through her once fair provinces. In this respect, she stands a warning to every true patriot, though it is satisfactory to know that even this confusion had not taken place until the civilized portion of the globe have availed themselves of the treasures once possessed by Spain alone, but now happily spread to nearly every corner of the earth.

One reference that we will make to exemplify the results of a judicious system of sheep husbandry, is to that of Germany, standing as she does before the world, as the greatest exporting wool country known. It is to be borne in mind, that previous to the year 1765, Saxony was not a sheep raising country, and that it was entirely owing to the enlightened policy of her then ruler, who enforced his views, especially amongst his own tenantry, making it a part of his agreement with those to whom he rented, that they should keep a certain number of sheep. And let us now see her condition. It appears from the parliamentary documents, that the wool imported from Germany into England, in the year 1841, amounted to 20,953,775 lbs., being more than a third of all the foreign wool, including all the colonies, imported into that kingdom in the course of that year.

Let us also look at the wool producing colonies of England. That of New South Wales, established in 1787, under all the disadvantages of her convict and criminal population. In the year 1841, (a period of 54 years from her first settlement,) she imported into England 7,993,060 lbs. of wool; while her more infant establishment of Van Dieman's Land, sent into the mother country 3,507,531 lbs.—and it is worthy to remark, that the first ship landed in that island did not take place till 1807. The total amount of wool imported into England during the year 1841, was 56,170,974 lbs., (which is presumed to be equal to the amount grown in that country)—making a total of 112,341,948 lbs. It also appears that there was, at the close of the year, 6,912,060 lbs. of foreign wool in bond, and, presuming there was about the same amount of home grown wool unmanufactured, the amount used in the manufacturing establishments of England for 1841, would be as near as possible 100,000,000 lbs.

We have not at hand any report of the amount of wool grown in the United States in 1841, though we have of that of her imports, which, it appears, was 11,409,764 lbs. In 1839, the wool grown in this country was 34,802,114 lbs.; and the probability is, that the amount was not much increased in 1841, which, if we take as a data to work upon, we have a total of 47,211,878 lbs., being nearly one half the amount manufactured by England that year.

Our imports of manufactured woolen goods, from England alone, in that year, amounted to £1,521,880, or $1,366,353—so says the parliamentary report. What amount we imported from Germany, France, &c. we are at present uninformed of. That France is manufacturing extensively, and that she is short of the raw material, we are assured, from the fact of her having agents through the whole Western and Southwestern States, engaged in the purchase of every quality of wool; and, taking all these circumstances into consideration, we have this state of things presented before us:

First, that as a pastoral people withal, and beyond the necessary resources under our control, we do not grow sufficient wool for our own use, but import upwards of $10,000,000 worth of manufactured woolen goods yearly to meet our demand for that article, besides a large proportion of the unmanufactured material. That, as a commercial people, upon which we pride ourselves, we are too careless to take advantage of and meet the wishes of a good customer for an article which we can raise in the greatest abundance, and at a certainly larger amount of profit than any people. Will not our farmers reflect on these things? Once again, with a view to drawing their attention to the subject, we inform them that every farmer in the State can have cash for every ounce of wool he can raise, at more than remunerating prices; that one house in Nashville alone, is authorized to purchase 1,000,000 lbs.—indeed, an unlimited amount for French exportation; that home consumption must necessarily increase; that, with ordinary attention, the quality and staple of the wool itself will be so improved as to produce a greater return; that our particular section of country is better adapted to sheep raising than any other in America; that our climate is such that we can do all Spain or Australia can accomplish; that, indeed, nothing is wanting but the judicious action of the farmers of Tennessee in the improvement of their breed of sheep, and an expansion of their flocks, to insure themselves and the State at large a position unequalled in the annals of agricultural history. C. F.

From the American Farmer.

Washington's Opinion of Agricultural Life

It is refreshing to us, and we hope it is to every lover of freedom, to read anything from the pen of Washington—and still the more refreshing, when it may happen to be upon the subject of Agriculture. In the belief then, that the following opinion of the farmer's life, from the Father of his country, may serve to reconcile every tiller of the soil to his lot, we give it insertion. But why need we say, that it may serve to reconcile the tillers of the soil to their lot? Surely there is no man owning a farm who is discontented with his position; for, of a truth, if there be one condition more than another, which any man might desire without incurring the sin of covetousness, it is to be the owner of a good farm, well stocked, to be out of debt, to have a good wife, and a family of children around him. There are other situations where a man may possibly make more money. The merchant, for instance, may realise more profit in a month, than a farmer would in half a life time. But then, where one merchant *dies rich*, there are ninety-nine who become bankrupt—and then, their gains, if gains they make, are realized amidst the cares, anxieties and tortures of the mind; for their's is a life of hazard and uncertainty, dependent upon so many contingencies for success, as, in numerous instances, to make even the most brilliant success, a dear price for the wear and tear of mind and the laceration of feelings. While the owner of a fertile farm, unless avarice be his besetting sin, has everything around him to gratify all the aspirations of his heart, sweeten the pathway of life, and make him happy. Come what may—drought or rain—luxuriant crops or short ones—high prices, or low ones—if he be prudent and frugal, the bosom of the earth, in its generous yieldings, will always afford to him and his, both food and raiment, and a little to spare, either to be laid by for a rainy day, or dispensed to his fellow man, in "binding up the wounded heart, or pillowing the aching head;" and what more, pray let us ask, does man want while he may be permitted to remain on earth? He that wants more is not imbued with that becoming sense of gratitude which is due to the author of his being. Riches, we are aware, have their attractions, and often weave around the brow of the undeserving chaplets which but ill become it. We are aware also, that although an eminent philosopher hath said that "knowledge is power," it would have been much nearer the truth, had he said, that *wealth* is power—but with this belief firmly impressed upon our mind, by the daily evidences of tame submission to the power of money by which we are surrounded—still, we would not exchange that glorious state of independence which belongs to the thrifty owner of a homestead of two or three hundred acres of good land, for any other condition. Although such an one may amass wealth slowly and moderately—though he may realise but a competency, still that wealth, or that competency, is earned by the most pleasurable, healthful and virtuous of all human pursuits.

But as we find ourself running riot under the influence of enthusiasm, we must cry halt, and introduce the opinion which Washington entertained of the calling of an Agriculturist.

In one of his letters to *Arthur Young*, Gen. Washington used the following language:

"The more I am acquainted with agricultural affairs, the better I am pleased with them; insomuch, that I can no where find so great satisfaction as in their innocent and useful pursuits. In indulging these feelings, I am led to reflect how much more delightful to an undebauched mind, is the task of making improvements on the earth, than all the vain glory which can be acquired from ravaging it by the most uninterrupted career of conquest."

Nutritive Qualities of Tea.—M. Peligot states that tea contains essential principles of nutrition far exceeding in importance its stimulating properties; and shows that, as a stimulant, tea is in every respect the most desirable object of habitual use. One of his experiments upon the nutritive qualities of tea, as compared with those of soup, was by no means in favor of the latter. The most remarkable products of tea are: 1st, the tannin or astringent property; 2d, an essential oil to which it owes its aroma, and which has a great influence on its price in commerce; and 3d, a substance rich in azote, and crystalizable, called *theine*, which is also met in coffee, and is frequently called *cafeine*. Independently of these three substances, there are eleven others of less importance, which enter more or less into the compositions of tea of all the kinds imported into Europe. What was more essential, as regards the chemical and hygienic character of the plant, was to ascertain the exact proportion of the azoted (nitrogenized) principle it contains. M. Peligot began by determining the total amount of azote in tea, and finished by finding that it was from 20 to 30 per cent. greater than in any other kind of vegetable. M. Peligot states that by reason of this quantity of azote, and the existence of cafeine in the tea leaf, it is a true aliment.

Fruit.—The demand in England for American fruit is likely to become a matter of considerable importance. A large quantity of apples was sent there last season and paid well. Many orchards of five, ten and twenty thousand trees have lately been planted in the Hudson River Counties, with a view of growing apples for export to foreign countries. We see no reason why peaches from New Jersey, and other Atlantic regions where they will grow, cannot be sent to England by steamers, and arrive in good condition.—*Newark Advertiser.*

Manures.

We extract the following excellent remarks from an article appearing in the South Carolina Temperance Advocate:

In the application of manure we should have an eye to its permanent benefits. We should guard against its waste: and that method is to be preferred which best secures us against this.

There is a popular opinion that manure *sinks:* that although it may be wasted, to a certain extent, by evaporation, the principal waste is occasioned by its actually descending into the earth, by the action of rains, until it gets beyond the region occupied by the roots of the crops to be cultivated, and ceases to do them any good.

If this were so, to any practical extent, it would be a very good thing: for it would deepen the soil; and we should have nothing to do but to plow deep, and turn up the manure again before it sinks too far; when it would have its former effect upon the crop, until it should sink a second time. And this operation might be again repeated, with the like beneficial results. It would follow, too, that the pervious soil would be the most valuable for manuring; because it could sooner and more easily be made deep.

But is the popular opinion true, that manure is wasted by sinking? I shall proceed, in the first place, to prove that it is not; and then, to show the wrong practices that have flowed from it, and will continue to flow from it, so long as it holds possession of the popular mind.

That manure does not sink beyond a proper depth, may be easily ascertained by very simple experiments and by a very little reflection.

Let any one who doubts, put a spigot in a common cider barrel, knock out the head of it, and fill it with clean sand, nearly to the top. Then let him pour upon the sand the most impure liquid manure he can find. He will be able to draw from the spigot nearly pure water. The impurities, which constitute the manure, will have been detained by the sand, by filtration, within a short distance of the top of the barrel.

It is upon this principle that farmers are in the habit of clarifying their cider. It is also a well known method among grocers for freeing their liquors of objectionable matter; and every confectioner habitually employs it in his business.

If we look to the operations of nature, we shall recognise it there. If the impurities, on or near the surface of the earth, were carried down by rains, we should never be able to get a palatable drink of water. But the beneficent Parent of all good, has, in the beautiful arrangements of an all-wise Providence, so ordered it, that the rain which descends upon the surface of the earth, shall be drained of all its own impurities, and of those it encounters near the surface, by passing through the superior strata; and it gushes out, pure and transparent, in refreshing springs and wells.

I take it for granted, that whoever bestows a little reflection upon these things will be convinced, that the opinion that manure sinks beneath the reach of the roots of cultivated plants, is entirely erroneous.

It is an indubitable fact, however, that after a time, manure does cease to produce any sensible effects? I think it occurs by evaporation. Perhaps a few simple experiments will establish this.

If you enclose a portion of manure in a box, and place it where it shall not be exposed to the action of light and heat, it will retain its fertilizing qualities, for almost any assignable time; and will even acquire, from the atmosphere, (if accessible to it,) an addition to them. But, if you place it on a board or stone, or in a tin box, open at the top, but enclosed at the sides, (a method which I select, as rendering it certain that no part can sink, though it may escape at the top,) and then expose it to the rain and sun, or to the sun alone, it will, in a very short time, become entirely inert, and its escape will be rapid in proportion to the intensity of the heat to which it is subjected.

There are other proofs. Every body has observed the rapid deterioration of land, exposed to the sun, without the benefit of trees, or of a crop, to shade it.

Having thus learned that manure is not wasted by *sinking*, but by *evaporation*, this may be the proper place to inquire the reason of the well known fact, that, when covered at the same depth, it is wasted sooner in sandy than in clay land. This depends upon the superior heat of the one over the other; which, of course, causes a more rapid evaporation. And this, again, may be ascertained by a simple experiment.

If, at any given hour of a summer day, you insert a thermometer in two contiguous soils, one abounding in sand and the other in clay, or insert it in two boxes, the one filled with sand, the other with clay, you will find the temperature of the former to be several degrees higher than that of the other. The necessary inference from this I have already stated.

We have now seen the popular notion of manure sinking, is an error. That on the contrary, it evaporates. We have seen that this arises from heat; and that this abounds more in sand than in clay.

The universal practice, which has followed that popular erroneous opinion, has been to deposit manure shallow in the sand, from an apprehension that it might sink, and, of course, would sink more rapidly in that kind of soil, which is more pervious than in clay, whish is less so. And so long as this abstract notion that manure sinks, prevails, so long will this practice prevail, as the necessary consequence of it.

I have shown that *manure does not sink, but evaporates:* and evaporates more rapidly from sand than from clay. What is the necessary inference? Is it not *that the practice of making a shallower deposit in sand than in clay, should be* EXACTLY REVERSED? The danger of evaporation being greater in the former than in the latter, the deposit should be deeper to avoid it.

I might extend this paper by other practical remarks and inferences; as, for instance: that the evaporation of manures being established, it is of importance in all cases where other circumstances will permit, to deposit them deeply, not only with a view to the permanent improvement of the soil, but to prevent the unhealthy contamination of the air by the deleterious gases escaping, by evaporation, from the fertilizing matter. Liebig's work, and that beautiful little treatise, "*Popular Vegetable Physiology*," might have been consulted with advantage by all, but I would particularly recommend the latter as containing the science of the former in a more attractive form, and in a style level with the plainest understanding. COATSWOOD.

MAKING COMPOST.

Capt. Abel Moore's Statement to the Committee of the Middlesex (Mass.) Society.

The importance of manure to the farmer is so apparent, that the manner of increasing it, in quantity and quality, without reducing the value of the same, becomes a matter of interest to all who are engaged in agriculture; and it is a well established fact, that manure can be more profitably used as a compost, than in any other way.

My attention was particularly drawn to the subject of making compost manure, about five years since, for at that time I could not purchase stable manure, without paying more for it, than the real benefit derived from its use. About that time, I built a barn 80 feet long, by 40 feet wide, with a cellar under the whole of it, and I then began making compost in a way that proved more profitable than I had previously found. I began by fixing troughs in the cellar, under the holes were I put down the manure, with hogsheads placed under the same to receive the urine from the cattle, and when full, I placed a bed of loam and peat mud and emptied the urine on to it, and set them again.

I have always kept hogs in my barn cellar, and, for the last three years, have kept two yoke of oxen, seven cows, one bull, and two horses, through the year. I tie up the cattle in the barn every night to save the manure; and in addition to the above, I have usually wintered from twenty to twenty-five head of young and fat cattle, and oxen.

For the last two years, I have adopted a new method, which I think is better than any other that I have tried. I always kept at hand a plenty of good loam and peat mud, both in my barn-cellar and barn yard. I have windows opening from the cellar into the yard, through which I put down most of the loam and mud, and place it under the holes where the manure is put down, and after it has remained there about one week, I spread it over the hog-styes in the cellar, which are 80 feet long by 24 feet wide; but before spreading the loam or mud, I sow corn on it, which will cause the hogs to root and turn the whole over.

So valuable do I consider urine for compost manure, that I have barrels placed in my sheds to receive the urine from the house, which are emptied on to the manure heaps when full; and also, I have plank troughs made on runners, placed under two privies, and when they are partly full, I hitch on a yoke of oxen and draw them to the barn cellar, and bury the contents in the loam and mud.

At intervals of a few weeks, I mix in lime, salt and plaster, at the rate of about one bushel each of lime and salt and a bushel of plaster to a cord of the compost. Lime aids the fermentation, and the salt and plaster, I believe, have beneficial effects on most of my lands.

I always fork over my manure very light before using it, and cast it out of the cellar and yard twice a year.

There can be no better economy in the making of compost manure, than by adopting a course of using the urine of cattle to the best advantage. Filling up the hog pens with loam and mud at about the same time, and allowing it to remain until it is wanted for use, does not, in my opinion, answer so good a purpose as putting the loam, &c. in as fast as it becomes saturated with urine. In the one way, your compost is well mixed with the droppings and urine of the cattle, and in the other the droppings are all on top before it is forked over, and but partially saturated with the urine.

The urine of cattle, I think, possesses as strong and enriching qualities, when properly applied to loam or mud, as their droppings.

Peat mud can be easily rotted and fit for making compost, by digging the same in the summer or fall of the year, throwing it into moderate sized heaps and allowing it to freeze and thaw during the winter.

Very truly yours, &c. ABEL MOORE.

From the New York Farmer.

The dung of horses, sheep, and of cattle generally, act as fertilizers only in proportion as they are combined with certain soils. On sandy, calcareous soil, they are very profitable—such soils being deprived of the silicate of potash, and of the phosphate; while on a dry soil, rich in potash, or on a soil formed of the ruins of granite, of porphyry, or clingstone, these manures are of little value. On the contrary, poudrette is an excellent fertilizer of such soils.

The efficacy of urine as a manure is well known in Flanders. In China, the people are prohibited by law from throwing that and the excrement away. China is the country of experiment; ages have given to the people discoveries of all sorts, which Europe achieved, but could not imitate; for the Chinese books give no scientific accounts; they give mere receipts for their operations. The last half century has, however, given us not only the knowledge which enables us to equal them in many arts, but to surpass them; and this advance among us is due to the judicious application of chemistry. But how far in the rear is our agriculture still, when compared with the Chinese. They are admirable gardeners; they know how to give each plant its proper education; to prepare for it its appropriate soil. Among them agriculture has attained the highest degree of perfection. In that country, which differs from ours in natural fertility of soil, they attach very little impor-

tance to the dung of animals. Among us, we have written huge volumes, but made few experiments. In China, they never manure their grain crops, except with human excrement—while we scatter over our land the dung of animals, full of all manner of weeds, the seeds of which are undigested by the animals, and which spring up with great power among our useful plants. We need not be astonished, then, that in spite of all our efforts, the noxious weeds cannot be extirpated from our fields. A celebrated botanist (Ingenhouse) who visited China with the Dutch embassy, states that it was impossible to find in a Chinese field of grain, one single weed.

In agriculture, the grand maxim is to give back to the soil in full measure (no matter in what form) all that is taken from it by the crop; and to regulate that, by the wants of each particular plant. The time will soon come, when we shall no longer manure our lands with the solid manures, but with solutions exactly suited to the crop desired.

Of dry horse dung, upwards of 70 per cent. is mere water. The dung of a horse well fed with chopped straw, oats and hay, I found to contain, when dry, only ten per cent. of the solid parts of those substances. Therefore, in carrying upon your farm two thousand pounds of horse dung, you carry on to it fifteen hundred pounds of water, about four hundred pounds of vegetable matter, and only about one hundred pounds of the salts necessary for another crop of hay, straw and oats, which your horses have eaten. These salts are essentially composed of phosphates of lime and of magnesia, and silicate of potash; the latter salt should predominate in the soil, while the phosphates abound in the grain.

[*Translated from the Revue Scientifique et Industrielle, by* H. Meigs.

From the Albany Cultivator.

SAVING MANURES.

The effluvium or gas, arising from decomposing animal or vegetable substances, though exceedingly disagreeable to our olfactory senses, is the congenial food of growing plants.

Arthur Young said, many years ago, "he who is within the scent of a dung hill, smells that of which his crops would have eaten if he would have permitted it." Sir Humphrey Davy demonstrated this. He placed a quantity of fermenting manure in a retort, and ascertained that it gave off a liquid containing a large proportion of salts of ammonia. Seeing this result, he introduced the beak of another retort filled with similar dung, under the roots of some grass in the garden, and "in less than a fortnight, a very distinct effect was produced on the grass, upon the spot exposed to the influence of the matter disengaged in fermentation; it grew with much more luxuriance than the grass in any other part of the garden." It is hence obvious that by permitting the escape of the gas evolved during fermentation, the valuable portions of the manure are dissipated in the atmosphere.

"The loss of *gaseous manure*," says Mr. Hannam in his excellent essay on the Economy of Waste Manures, "arises from the escape of the carbonic acid and the ammonia, of the vegetable and animal matters in the manure heap, during the process of fermentation and putrefaction; both of which gases are essential in the nutrition of vegetables. * * * When this evolution of ammonia and carbonic acid takes place under the root of a plant, it is what we want; but when it takes place, as is generally the case, months before the compost is used, the manure is robbed of its most valuable constituents."

"It is worthy of remark," continues Mr. Hannam, "that the richer manure is in nitrogen, the more serious the loss is; as the more nitrogen a substance contains the more prone it is to ferment and throw off ammonia." The observation of every farmer will corroborate this; for all have noticed that the richer the manure the stronger the odor arising from it.

The most effectual means, probably, of preventing this waste of the gaseous portion of manures, would be to apply them to the soil before fermentation takes place. In this case the gases would be taken up by the growing crop.—Stable or barn manure, is sometimes deposited in cellars, where, from the low temperature, and seclusion from the air, it undergoes little or no change. Thus kept, it retains its original strength, and is much more powerful and enduring in its effects, than that which has undergone decomposition in the open air. But there is often so large a portion of undecayed vegetable fibre, (litter, &c.) in manures, they cannot conveniently be applied in a green state. Besides, for some crops, the action of green manures is not quick enough; and for other crops, as wheat and other small grains, they tend to promote too great a growth of straw, and increase the liability to rust.

It becomes, then, necessary under certain circumstances that manures should pass through a state of fermentation before they are applied to the soil, and the question is, how can this object be accomplished without loss?

Reason teaches, and experience proves, that substances must be mixed with manure, which will absorb the gaseous portions as they are generated. *Earth* is a good absorbent. If a dead animal be enveloped in the earth before putrefaction commences, and allowed to remain so until the carcass is decomposed, the earth will have absorbed the nauseous fumes occasioned by the decomposing animal matter, and will be found rich in those principles which constitute the food and growth of vegetables. This example teaches that mixing soil with manure or covering the manure heap with a layer of soil while undergoing fermentation, will preserve much of its value which would be otherwise lost. There are other substances which are preferable to common soil—such as charcoal, (which will absorb ninety times its own bulk of ammoniacal gas, and thirty-five times its volume of carbonic acid gas,) and peat or swamp muck. The latter in many parts of the country, can be had in the greatest abundance, and it is, beyond doubt, one of the best means of augmenting the farmer's stock of valuable manures. In its composition and absorbing power, it much resembles charcoal—being principally the carbonaceous matter of decomposed vegetables. Every farmer who can conveniently obtain peat or muck, would do well to place a layer of it under all his manure heaps—to mix it with barn or stable manure in forming composts, covering the piles with a coating of it to prevent the waste of the gases, and throwing it liberally into the stalls of horses and cattle, to absorb the urine. Results will show that the labor thus bestowed in the use of swamp muck, will be rewarded a hundred fold.

Other substances are used as *fixers* of ammonia, &c., which act somewhat differently from those above mentioned—such as gypsum, and various kinds of acids. The theory of their action is, the ammonia, being an alkaline gas, will by combination with any acid, form a neutral salt. Gypsum is a combination of lime and sulphuric acid. When this is applied to fermenting manure, the sulphuric acid of the gypsum leaves the lime and unites with the ammonia, the acid having a stronger affinity for the ammonia, than for the lime with which it was combined. Mr. Hannam in the essay before referred to recommends that the manure heap be covered with peat or some absorbent, and "this coating kept well saturated with sulphuric acid and water, say a weak mixture of ten gallons of water to one of acid." Mr. Hannam adds, that any other acid which may be obtained at a cheaper rate, will act as well, as the ammonia will combine with any acid. Either the application of gypsum, or the acid solutions mentioned, will soon affect such a *fixture* or combination, that little or no smell can be perceived.

In regard to the use of *salt*, which has been by some recommended as a fixer of ammonia, Mr. Hannam says—"My own observation teaches me to prefer acid to any salt, as it is equally cheap, more easily used, and is, therefore, likely to be more efficacious."

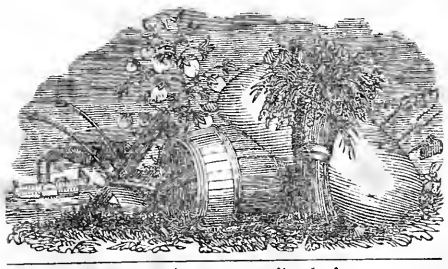
To Prevent Rust in Wheat.

From the Farmer's Register.

"As far as my observation extends, lime is an effectual preventive of the rust. Putrescent manures and clover lays, on the contrary, almost always induce it if the season be at all unfavorable at the critical period of ripening. The reason I take to be this: putrescent matter, by furnishing more food than the plant can elaborate, produces a state of plethora, which results in the extravasation of the sap at the season of greatest vigor. This indeed I understand to be the theory. The tendency of lime is to check this redundancy of growth, by providing in some way the specific food of the plant. Whether this be done by enabling it to decompose carbonic acid with greater activity, or by furnishing it with silicate of lime, or by contributing to the development and formation of the grain, rather than to an exuberant vegetation, cannot perhaps be determined. When I was in the great wheat growing district of western New York, some years ago, I saw fields of wheat that I was told would yield twenty-five or thirty bushels to the acre, which I could not have supposed, from any previous observation, would have produced more than ten. The soils of that region, being of a diluvial formation, are so rich in calcareous matter, from the former attrition of the lime rocks scattered over the country, that they frequently effervesce with acids. The stem had so little blade that it appeared almost naked. Plaster of Paris, which has been recommended as a protection against the rust, though it be lime in another form, does not contribute much to the formation of grain. Its tendency is eminently to increase the bulk of vegetable growth, and therefore, when it acts on wheat, to induce rust and mildew. To guard against the rust then, such application to the soil appears necessary as would afford specific nourishment to the seed. In every analysis of wheat there is found a portion of lime. There are also some manures that furnish the specific ingredients, but those only, I believe, which are concentrated in their energy. I have read nothing lately which sheds more light on the distinction I have attempted to draw, between manuring for the grain and manuring for the straw, than the detail of some experiments with guano, by J. E. Teschemacher, of Boston, and contained in his address to the Horticultural Society. Some plants treated with guano, the balsam for instance, produced very inferior flowers; but not a flower missed bearing its seed vessel, and every seed vessel was filled with perfect seeds; while other plants of the same species and growing under the same circumstances, with the exception of the guano, had only a portion of the seeds perfect in each pod, though the flowers were very fine.

"There is a neighborhood in Maryland which I occasionally visit, the inhabitants whereof form a little community of intelligent and industrious farmers, who mostly belong to the same society of which I am a member, namely that of the Friends or Quakers. They do their own work; and when one works with his own hands, he is more likely to make both ends meet. They find it to their interest to haul lime from six to ten miles to apply to a soil by no means naturally fertile. The crops of wheat on their limed lands are invariably good, and but little affected by rust.

"A few years ago, a friend of mine, in an adjoining county, planted an acre or two of ground in pumpkins. The vines were so much infested with bugs that he sprinkled caustic lime over the leaves for the purpose of destroying them. In the fall the lot was seeded to wheat, and at the ensuing harvest the locality of every hill was conspicuously visible. In each spot where the lime had been applied, the straw was bright and of a golden color, without the least appearance of rust, while in every other part the wheat was completely ruined. If it is not too late in the season, I would suggest the trial of a small piece of ground with lime or ashes, if it was no more than a few yards square. Ashes would be as beneficial as lime, for they afford potash.



The Southern Cultivator.

AUGUSTA, GA.

THURSDAY, MAY 1, 1845.

Correspondents.

It would not be a very difficult task to make the Cultivator a scientific paper, filling it with the speculations of philosophy, and extracts from Chaptal, Davy, Liebig, Johnston, Boussingault, and others. But this is not what the country wants just now. A paper so made up would not find many readers, simply because what would be offered to be read, would be too far removed from the every day business of the planter. What we want now, is a plain account of the experiments of men of plain common sense. There are now but few persons engaged in tilling the soil who do not believe that old processes may be varied with certain benefit to the crop and profit to its owner: and thus believing, they are very likely to make experiments of some sort or other, and note the results. When they meet their neighbors on public occasions, these experiments and their results are the subject of conversation, unless party politics should happen to exclude every thing else. It would not be much trouble, of a long winter night, or a rainy day, to write out an account of these experiments for publication in the Cultivator. Now, this is just what we want: that our planters shall enlarge the sphere of their conversation, and besides talking with their immediate neighbors, shall talk through the pages of the Cultivator with men engaged in the same pursuit, one hundred miles distant; that the planter on the Savannah River shall talk and compare notes with the planter on the Chattahoochee, and he of the mountains with him of the sea coast, without leaving their own firesides. But, you say you can't write. You can talk, though; and all you have to do is to banish the idea so prevalent, that when you take pen in hand you must get on stilts, and go hunting big words in the Dictionary, wherewith to construct high sounding sentences: thus trying to write in a style and manner altogether different from that you use when talking to your neighbor. Banish this notion altogether; take your pen, and put down on paper, just *what* you would say to your neighbor—just *as* you would say it when speaking of your experiments, and you will then succeed to a certainty. If there should be some errors in spelling and grammar, never mind that—we will take care to have every thing right in that respect.

When the country shall have become deeply interested in the results of experiments thus detailed, then will be the time to bring forward the science of the matter; then men will begin to be anxious to know the plain why and because of these results. Then we may venture to introduce a larger portion of philosophy into the pages of the Cultivator. But, for the present, for the great mass of our readers, we want just such articles as our paper of to-day contains, over the signatures of our correspondents; these we can safely recommend as specimens of what planters should write about, and of the way in which it should be written.

When we shall be able, with the Albany Cultivator, to boast of having three hundred correspondents, most of them practical, working planters, and shall have such a subscription list as will warrant our incurring the expense necessary to make the Cultivator, in other respects, what we wish it to be, we shall feel that we have not lived altogether in vain.

Silk.

We have received the specimens of domestic silk referred to in the letter of our correspondent, Mr. Cassidey, in another column. They are deposited in the store of Messrs. Newton & Lucas, Athens, for the inspection of those persons who take an interest in such matters. All who have seen them, pronounce them to be very beautiful.

We have on hand, and shall insert soon, perhaps in our next number, "A brief History of the Silk Culture in Georgia," by the Rev. Wm. B. Stevens, of the University of Georgia. It is a very interesting account of the efforts of the Trustees to establish that culture in Georgia; and having the advantage of being compiled from the records of the Colony, every statement in it may be received with implicit confidence in its accuracy.

The Agricultural Press.

Since our last publication, we have received the first number of the "Arkansas Farmer," published, monthly, away over yonder at Little Rock, by J. Gish, and edited by an association of practical planters. It is a very creditable publication, indeed, to all the parties connected with the getting of it up; and if the planters of that region will only read it carefully, they cannot fail to be very largely benefitted by it.

Then there is the "Plow Boy," a brisk, lively, good humored little fellow that "comes whistling o'er the lea" from Cincinnati. He proposes to give you a lecture, monthly, on all that appertains to the life, occupation, and well-being of a farmer, and asks you only twenty-five cents a year for it.

And from Cleveland, Ohio, we have the first number of "The Western Reserve Magazine of Agriculture and Horticulture," a very neat and well filled octavo of 24 pages, monthly, and pictures to boot, at one dollar a year, by F. R. Elliott.

The Albany Cultivator acknowledges the receipt of thirteen thousand subscribers from 1st January to 1st April—just one thousand a week, all paying too in advance. This is creditable to Northern farmers, and shows clearly that they perfectly understand the secret of keeping the people of other States who don't read tributary to them. When will Southern planters act with so close a regard to their own interest, as to extend the like amount of patronage on the Southern Cultivator?

More Rasping.

The two pictures in the last number of the Cultivator, of Southern planters and their economy, so admirably drawn, resembled the originals so exactly, that we are sure our readers would like to have more of them. Accordingly, we have selected another, not a whit inferior, in point of accuracy, to the other two. See the extract below, from Mr. Gregg's essay.

It would be a very interesting matter to ascertain exactly what has become of the proceeds of the cotton crop of Georgia, since it first became an article of cultivation here, or even for the last ten years. Suppose that, for the period last named, the average crop has been two hundred and fifty thousand bales, of three hundred and fifty pounds each, and that the average price has been ten cents per pound. This would give a gross income, for the ten years, of eighty seven and an half millions of dollars. Now, what has become of this immense amount of wealth, created by the culture of cotton in a single State? It is certainly not to be found among ourselves. We must look for it in Kentucky and Tennessee, New York, Boston, Lowell, &c. Indeed, over the whole of the Northern States there may be found decisive evidences of its lavish expenditure. And it would be a very curious matter to ascertain exactly how much of it has gone West, how much North and East, and how very little of it is where it ought to be, that is, among ourselves, who created it.

In this matter of absenteeism, by which so large a portion of the product of Southern labor is transferred to the North, without a substantial equivalent, if there were any reciprocity, between the North and the South, the result would not be so ruinous to us. But though we go North yearly, and spend our money there profusely, who ever heard of Northern people coming South and doing the same thing among us. Oh, no—they are too keen for that. Even those who are compelled to come South during the winter, on account of health, often contrive by engaging in some business or other, to return in spring better off than when they left home. Their plan is to stay at home, unless compelled to seek a milder climate in winter; or if they do travel for pleasure, to go any where but to the South: thus taking care to keep up the drain upon our resources, getting from us all they can, both by their own efforts and by the system of national legislation they have forced upon us, and keeping all they get. Nor are they to be blamed for all this. They are but obeying the dictates of what has always been human nature. They are only doing what people have done in all ages of the world, since the words "property" and "money" were first known, and the things signified by them, understood. It is we of the South, who have been such simpletons as to allow ourselves to be fleeced in this manner, who ought to be scourged from folly. Mr. Gregg says:

"One would not suppose that the South was laboring under embarrassments, if he were to

see the crowds that are continually thronging the Northern cities and places of amusement. I have heard the number variously estimated at from 40 to 60 thousand in one summer. Taking the lower estimate of the two, and allowing for the expenses of each individual $300, (and this is certainly below the mark,) we shall have $12,000,000 transferred yearly from the South to the North, by absenteeism. As bad off as we know South Carolina to be, yet we are certain she furnishes her full *quota* of this immense sum. Go where you may, in the city or out of it—in what direction you please, and you can scarcely set your foot into a railroad car, in which you will not find some half dozen persons from this State. The register book of every fashionable hotel that I visited, exhibited a large share of names, with South Carolina attached to them. Nor are our people remarkable for their economical habits, as the bar-keepers will inform you, that their wine bills exhibit liberality even to wastefulness. You may see them, too, flying around cities, in the finest and most costly equippages that money can procure, and while a *millionaire* of New York is content to ride in an *omnibus*, from Wall-street to the upper part of the city, many of these persons, not worth ten thousand dollars, would be ashamed to be seen in such vehicles. With tailors, milliners, mantua-makers, &c., these persons are considered to have gold without measure, and it is a perfect *windfall* for them to meet occasionally with one. You cannot step into a furniture store, carpet warehouse, or dry goods establishment, where fine silks and laces are sold, without meeting persons from our State, making lavish expenditures and purchasing thousands of articles of wearing apparel, which are not worn until they return home, where the same articles can be obtained in stores of our own tradesmen, at cheaper rates than those at which they were purchased at the North.

"At one tailor's establishment in Boston, I was informed by the propricter, that his sales for the last year, to Charleston alone, amounted to upwards of $50,000, and this year he expected they would reach $80,000. How much trade others in Boston in the same business receive from Charleston, and what amount falls to the lot of the fashionable clothiers of New York and Philadelphia, cannot be estimated, but there is little doubt, that the amount would be found quite sufficient to support three or four fashionable establishments in our own city."

Subsoil Plowing.

We cannot impress too strongly on the minds of our readers the importance of subsoil plowing. In the Southern part of the United States, so liable, of late years, to long and parching droughts, it may be set down as being very nearly the first element of success. Manure is essential—just as essential to the well being of plants, as are corn and hay for animals. Yet, if there is any thing that will enable us to do with less manure than would otherwise be necessary, it is subsoil plowing; simply because, by loosening the soil to a greater depth, it furnishes to the roots of plants a more extensive range, in which to collect their food, and gives them a power of resisting drought which no one will believe possible until he shall have seen it.

We cannot get subsoil plows here except at a very heavy and unreasonable expense for transportation, there being no manufactory of the article at the South yet, so far as we know; and perhaps those made for Northern soils, even if we could get them readily, would not suit our purposes, in our light and exhausted soils. The best substitute will be to use a good turning plow to the depth of the top soil. In the bottom of the furrow run two or three times, as deep as it can be made to go, what is usually known as a coulter; turn the next furrow of top soil on to the subsoil thus loosened; then use the coulter as before, in the bottom of the new furrow—and so on, through the whole field. So great is the benefit of thus loosening the subsoil, that we have seen it confidently stated that the produce of any soil would be doubled by this process, without a particle of manure.

If any one would like to see subsoiling, as we have described it, effectually and neatly done, he has only to visit the plantation of Judge Dougherty, near Athens.

"By cultivation," says the American Farmer, from which we quote what follows, "the potash on the surface, originally existing in most soils, is taken up by the growing plants, and unless such soils be periodically *ashed*, in the course of a series of years, that portion of the land within the reach of the roots, must become deprived of this necessary element of its fertility, and hence it is, that soils which were once renowned for their wheat-producing qualities, cease to yield that grain in such quantities as to render its culture profitable. Without potash be present, the sand of the soil cannot be dissolved, and as that is the essential principle in the formation of the outer crust of corn-stalks, as well as that of all the families of small grain, as wheat, barley, rye, &c., the exhaustion of cultivation must either be supplied by the application of *ashes*, or some other alkaline substance possessing the attribute of dissolving the sand, and forming the compound called the silicate of potash, or the culturist must draw upon the *subsoil* for a supply. Hence, then, it is obvious, that there is no other way left, of procuring such supply from beneath the surface, in the first instance, but by breaking up the *subsoil*, and bringing it within the *indirect* chemical action of the solar and atmospheric influences, and ultimately of turning portions of it up to be *directly* acted upon by the same powerful agents; thereby not only commingling an important ingredient with the theretofore exhausted surface soil, but deepening the bed of the plants, and thus enhancing the range whence they derive their sustenance.

"If the subsoiling of land was productive of no other good effects than those we have alluded to, it would be worth four times the cost it may occasion. But there are other beneficial resulting effects. In *moderately* moist lands, by the process of percolation, which it encourages and augments, subsoiling serves to relieve the roots of the superabundance of water which, in tenacious clays, always abounds, and imparts to them the medium of healthful existence. We mention in this connection 'moderately moist lands,' because where they may be what is technically called *wet lands*, subsoiling might prove not to be an effectual means of draining, and it might be found necessary and proper to drain such lands by *covered or open drains*, prior to the operation of subsoiling. But even in wet lands it would be found highly efficacious, because, although the operation might not be sufficient of itself, yet it would prove of infinite service. By deepening the soil, moisture, in times of drought, would be much longer maintained than in shallow tilth, as it is a well established fact, that its tendency is upwards, and that that tendency is encouraged by the voltaic action of the roots—therefore, as a necessary consequence, the plants would draw a supply from the subsoil long after the moisture in the surface soil would have been abstracted by the sun and air.

"Having thus briefly stated our views of the good effects of subsoiling, we would be permitted to ask some of our agricultural friends, to make experiments to test the efficacy of subsoiling. This may be done by subsoiling an acre of corn ground, and simply plowing the adjoining acre, manuring and cultivating both alike, and measuring the product of each. We do not profess to be a prophet, but we will venture the prophecy, that the subsoiled acre would yield one-third more than the one which was not—and surely if an operation which will cost no more than the ordinary plowing of an acre will add so much to the production of the soil, no man should hesitate to make an experiment, because his *interest*—that great lever which propels mankind onward to exertion—will be inevitably promoted by it."

The Alpaca.

Mr. Allen, of the American Agriculturist, says: "Keeping Alpacas on the mountain ranges of the Southern States, would yield the planters large profits, and compensate them for the low price of cotton on the seaboard." Mr. Hatch, of the Western Cultivator, says: "In Virginia, North and South Carolina, and Georgia, there are mountains and highlands enough, if converted into walks for the sheep of the Andes (Alpacas,) as would, in a very few years, add a million to the annual income of those States."

We have here, from two remote and widely different quarters, New York and Indiana, at the same time, an indication of a new pursuit for the people of the South. That the introduction of the Alpaca would be attended with very great advantages, if it should succeed, we have no doubt. The wool is in great demand for the manufacture of the very fine and peculiar cloth so much prized by the ladies, three and an half millions of pounds having been imported into England last year.

The Alpaca is represented to be a very gentle, docile and graceful creature, living and thriving on coarser food than common sheep require, and enduring the winter better. Indeed, the principal difficulty attending the attempt to introduce them into England, is thought to arise from the excessive luxuriance of English pastures. But even with this disadvantage, the animal is found to come to maturity sooner, by two years, in England, than in the Peruvian mountains; and the fleece is increased from ten to seventeen pounds. Their flesh, when young, is eatable—the carcass weighing about 180 lbs. But the wool is the chief article of value, being fine, soft and silky, and commanding high prices and ready sales.

Alpacas can be bought of the Earl of Derby, near Liverpool, for about two hundred dollars per pair. But they can be brought from their native country at less expense. The first cost and expense of transportation to the shipping

port, it is said, will not exceed $5 per head; cost of transportation to a port in the United States, is supposed not to exceed $20—making cost in Charleston or Savannah, $25. To this, should be added the expenses of a native shepherd, who should, in all cases, be got to take charge of the animals during the voyage.

English noblemen and farmers are bestowing great attention on the introduction of the Alpaca into England and Scotland; and thus far, their efforts have met with extraordinary success. Why should not our planters be eager to engage in an enterprise, that may add so much to the resources of our country? The only serious impediment that we can see in the way, discouraging every thing like enterprise in the business of wool growing, or the introduction of the Alpaca, comes from the multitude of worthless dogs with which the country is infested. Mr. Chiles, of Harrodsburg, Kentucky, recently lost seventy select fine wooled breeding ewes in one night, by dogs. It can't be too often repeated, that before our people undertake raising either Sheep or Alpacas, with any reasonable expectation of success, they must be supplied with the shepherd's dog. Of this most faithful and most useful animal, we add hereunto an account taken from the Salem Register, Ohio, into which paper it was copied from a late English work:

THE SHEPHERD'S DOG.

The shepherd's dog in his own department is a perfect miracle of intelligence. He understands the sign, the voice, the look of his master. He collects the scattered sheep at the slightest signal, separates any one that is indicated from the rest of the flock, drives them wherever he is told, and keeps them all the while under perfect control, less by his active exertions than by the modulations of his voice, which expresses every tone from gentle instruction to angry menace. These are his ordinary performances, visible every day in a thousand pastures. But he can do greater wonders. It chanced one night that seven hundred lambs, committed to the keeping of the Ettrick shepherd, broke loose from his control and scampered away in three divisions over hill and plain. "Sirrah, my man," said Hogg mournfully to his *colly*, meaning it for an expression of grief, and not for a direction, "they're awa." Silently and without his master's knowledge, for it was too dark to see, the dog left his side, while the shepherd passed the hours till morning in a weary and fruitless search after his wandering charge. At the dawn of the day he was about to return home with a heart full of despair, when he caught a sight of Sirrah guarding at the bottom of a deep ravine, not, as he at first supposed, one division of the lambs, but the whole of the vast flock, without a solitary exception. "It was," says James Hogg, "the most extraordinary circumstance that had ever occurred in my pastoral life. How he had got all the divisions collected in the dark, is beyond my comprehension. The charge was left entirely to himself, from midnight until the rising of the sun, and if all the shepherds in the forest had been there to have assisted him, they could not have effected it with greater propriety." On another occasion the same famous shepherd saw a dog, when it was utterly dark, put upon the path of a ewe that had been lost by her owner near a neighbor's farm, and which was supposed to have mingled with her fellows that were feeding in the surrounding pastures. "Chieftain," said the master of the dog, pointing to the spot from which the sheep had gone off, "fetch that, I say, sir—bring that back; away." And away he went, and back he brought, in half an hour, the identical sheep. A sheep-stealer, who was at last discovered and hanged, used to carry on his trade by secretly signifying the particular sheep that he desired out of a large flock, as he viewed them under the pretence of purchasing, to his dog, who, returning by himself a distance of several miles at night, drove the selected sheep, which was undoubtedly the fattest, to his fastidious owner. Both Scott and Hogg relate this picturesque story more circumstantially from the annals of the Justiciary Court, in Scotland. Sir Thomas Wilde knew an instance in which three oxen out of some score, had mingled with another herd. "Go fetch them," was all the instruction the drover gave his dog, and he instantly brought along with him those very three. A cattle dealer, accustomed to drive his beasts for nine miles to Alston, in Cumberland, once for a wager, sent them alone with his dog. The animal perfectly understood his commission. He kept the straight road, ran, when he came to a strange drove, to the head of his own to stop their progress, put the beasts that blocked the path upon one side, then went back again to the rear to hie on his charge, and thus adroitly steering his way and keeping his herd together, he carried them safely to the destined yard, and signified their arrival by barking at the door of the dwelling.

Agricultural Education.

Even in North Carolina they are going ahead of us in the business of agricultural education. An agricultural school has been recently established in Ashe county, in that State, under the patronage of Bishop Ives. The establishment comprises about five hundred acres of land, with the necessary buildings. The pupils are required to labor, only so much as may be necessary to illustrate practically the principles they are taught in the school. In all the branches of a liberal education, the course of instruction is thorough. The expenses are one hundred and twenty-five dollars per year, for tuition, board, washing and fuel.

In connection herewith, we copy from the Southern Planter a letter from Bishop Ives to the Editor:

Raleigh, March 12, 1845.

My Dear Sir—Many thanks for your very interesting and useful publication, which I have received; also, for the straw cutter, which I hope soon to receive. The progress in agricultural knowledge and improvement, is most gratifying. The evidences of increased interest in the subject here, are striking. The book merchants, Turner & Hughes, inform me, that during the late sitting of our Legislature, more books on agriculture were disposed of than had been for the *previous seventeen years*, the length of time in which they had done business in this place. This is encouraging, not only to the worldly economist, but to the Christian minister, for I regard the cultivation of the soil as intimately connected with the religion and morality of a country. My own observation has led to this conviction, and hence, in an attempt to do something for the spiritual interests of our roving mountaineers, I have felt it my duty to endeavor, first of all, to break up their habits of idleness and hunting, and infuse among them a spirit for the improvement of their rich, but neglected lands. Indeed, I look to the change of feeling now going on in favor of agriculture in this State, as one of the most promising signs of the times, both in regard to the physical and moral advancement of the people.

Excuse these quite unintentional remarks. At a future time, I may take up this subject in earnest, with a view to aid in the impression which your deserving periodical is slowly, but surely producing in favor of agriculture.

With the truest regard, your friend and servant, L. S. Ives.

We cannot close this article more appropriately, than by making an extract or two from an address delivered in October last, by Ralph R. Phelps, before the Hartford County (Connecticut) Agricultural Society; by the way, one of the very best of the very many good essays on domestic economy and home education, which we are indebted to the Yankees for.

Speaking of the disposition of young men "to leave the farm for a profession, a clerkship, a trade, or even a pedlar's trunk or cart," he assigns, among the causes of the prevalence of this spirit, "false ideas of honor and respectability, surly, morose and scolding habits of parents," and "the rough, uncouth and comfortless appearance of many farmers' houses and out-buildings." Mr. P. then proceeds to point out a remedy, as follows:

"Let no farmer's wife think her children too good to labor; but on the contrary, let her strive early to fix habits of industry. Let every mother teach her sons, that while labor on the farm is honorable, idleness, ignorance and vice alone bring reproach. And when this lesson is thoroughly impressed on the mind of her son, and corresponding habits are formed, that son will be likely to make an efficient man and a useful citizen, whether he be following a profession, or be engaged in the more safe and more pleasant pursuit of agriculture. But when the mother, without this lesson, and without these habits, undertakes to make her son a gentleman, she is far more likely to make him a loafer.

"Let parents labor to give all their children a good education. Let the absurd notion, that a farmer needs no education, be banished from every dwelling. There is no pursuit where intelligence and a well cultivated and a well disciplined mind is more necessary, than in the proper management of the farm. Let the mind be enlarged by a knowledge of history, political economy, and especially the sciences connected with agriculture. Let the young farmer enrich his mind by general reading. Let him thoroughly understand our political institutions; and be able to judge of his political rights and duties, without the aid of some demagogue, who had rather devote his time to watching over the public interests, than to the pursuit of honest industry. In short, let the farmer be able to reason, to examine and to judge for himself, and he will soon take the elevated rank in society to which his calling entitles him, and he will no longer have the opportunity of complaining that professional men have too much influence. This will have a great tendency to attach farmers' sons to their homes and to their farms."

For the Southern Cultivator.

Deep Plowing.

Mr. Camak—By your request, I give you the result of a trial made by myself the last year in deep plowing. Having received, late in February, several varieties of wheat, distributed from the Patent office, I immediately prepared a small piece of ground in the following manner: first, I ran a good turning plow and followed in the same furrow with a long scooter. I attended to it in person, and am certain that the ground was thoroughly broken, to the depth of *both plows*. The wheat, as I feared, was too late, and was destroyed by the rust. A thick coat of crab grass came up and was suffered to grow until August, when it was cut and cured—making, on about a quarter of an acre, three cart loads of most excellent hay of unusual length, measuring three feet and upwards. Indeed, it was the thickest and most luxuriant plat of grass I ever saw.

The land was *without manure*; the season was unusually *dry*, so much so, that I made but little over half a crop of corn. I had another piece of land left for the purpose of making hay, which I know to be a great deal richer, having had the drainings of the horse-lot for years.

This received one single plowing, but did not produce grass high enough to cut. These facts led me to reflect upon the cause of the difference between the product of the two pieces, without intending it as a comparative experiment. The result, together with the attending circumstances, satisfied me that the superior yield of the *unmanured* piece could be attributed alone to the thorough and *deep* plowing it received in the spring. Very respectfully,

WILLIAMS RUTHERFORD, Jr.

Cowpens, Walton Co., March 21, 1845.

For the Southern Cultivator.

Bread-Stuffs--A Contrast.

The consequences of an abundance of Bread-Stuffs on the prosperity of a Country, contrasted with an absence of that plenty and cheapness.

Any one who has occasion to visit the Northern States, observes, on returning homeward, a fact that startles him, in the difference presented to the eye, in the two sections of country. *There*, he sees an appearance of comfort; men of very moderate means live in neat houses; those of greater wealth in splendid ones; there seems to be a place for every thing, and every thing is in its place. *Here*, the picture is altogether different; people seem to regard their places of abode as necessary evils, and pay as little attention to making them either neat or comfortable as possible. They seem to esteem a house and its fixtures like an Arab does his tent, as something that is to be occupied for only a brief moment, and any pains and expense in adapting it to comfortable living, as an unnecessary waste of time and money. As to ornamenting the grounds around it, with trees and shrubbery, such an idea does not seem to have occurred to the occupant.

There, if you have occasion to stop at a house in the country, you find at the table, food prepared properly; and butter, milk, and seasonable vegetables are set before you. *Here*, you have that eternal dish—fried bacon, or pork, if it is winter, swimming in grease, "and nothing else," except "long *collards*" and bread. The owner may have his principal wealth in cattle, to the amount of many hundred, as is the case in some places, and if it is winter or spring, he has not an ounce of butter to offer you, and rarely even milk enough to put in your coffee.

Inquire the price of building a house *there*, and the amount is small. *Here*, the cost is so great, as to deter any one from building a good one, any where else than in a large town. It would be thought extravagance to entertain the idea in the country.

There is a cause for this disparity in the condition and appearance of these two sections of the same country. What is that cause? This question has been often asked in our presence, and the answer has always involved some abstrusity wholly irrelevant to the subject, in our view of the case. Are we less intelligent than our neighbors? Has a genial sun rendered us less capable of the use of our mental faculties than they? This will hardly be admitted. The real cause, from its very obviousness, seems to have been overlooked, in searching after remote ones. *It is because they produce bread and meat in abundance, and we do not.* That there are other auxiliary causes, in the way of unequal revenue laws, &c. which tend to raise one section and depress another, we doubt not; but the radical cause is the one we have stated, we believe.

In order to see its effect readily, let us suppose you have a house to build. You must have lumber, brick and lime; a carpenter is to be employed to build the house, a bricklayer to make the chimnies and plaster the walls. The sawyer asks you a price for the lumber that appears high, when taken in connection with the plenty and cheapness of water power and pine timber, but he solves the difficulty very soon, by telling you the price he has to pay for corn, to subsist himself, his hands, and his mules, which haul the stocks to the mill and the lumber away from it. Each mule, purchased from a Kentuckian, costs him $75 or $80, and the corn to feed them costs him, to assume the current rates in Macon at this date, 75 cents per bushel. It is easy to see the effect of this on lumber. The same reasons apply with the brick-maker, and lime-burner, precisely. Then go to the carpenter and bricklayer and tell them the price of building a house and a chimney and of plastering at the North, and ask them why they cannot afford to work at the same rates. They will tell you that living is cheap at the North, it is dear here. And you have a solution of the whole mystery, and build your house at twice the cost which would be necessary, if you lived in a country where provisions were plenty and cheap.

But here the farmer turns upon us, and asks, What is to become of me if I can get but 25 cents for my corn? We answer, that with an abundance of corn at that price, and every thing else at a proportionate rate, you will live more plentifully, more comfortably and independently in every respect; yourself, and the whole face of the country and its population, from the pettifogger to the pig, inclusively, will be better off and happier. What is the difference to the farmer in dollars and cents, if he gets 25 cents for his corn, and can build a house for $400, or if he gets 75 cents, and the house costs him $1200? It is as broad as it is long, so far as cost is concerned. But as to his comfort and the general prosperity of the country, there is a great difference.

There is this essential difference in the habits of a Northern and a Southern man. *The one*, whether in Connecticut or in Georgia, if he removes here permanently, thinks in the first place of making himself, as Baillie Nicol Jarvie says, "what he calls comfortable." Then he looks out as keenly as other men for the ways and means of getting rich, but he must be comfortable while he is doing it. Every thing must be neat and *tidy* about him. *The other*, without any systematic economy, is indifferent about the present, and lives altogether in the hope of realizing a fortune in the future, when he expects to live as he pleases. And when that time arrives, habit has grown to be second nature, and as to the enjoyments of life he is no better off than when he began—"Always to be, but never blest.—Frequently careless even in his personal attire, and always slovenly in the arrangement of his house, out-houses, gates, fences and grounds.

With every element of prosperity a country could ask, we of the Southern States are the most dependant on others, of any people within our knowledge; and the face of the land presents to a stranger the most poverty-stricken aspect of any that meets his eye anywhere.—This is a humiliating confession from a son of the soil, "one to the manner born," but however disagreeable, it is a truth that must be known and felt by all before the evil can be obviated. We scourge our lands by continuous crops of cotton, without a year of rest or rotation, and buy every thing; while others improve their lands and make every thing at home they can. Not to speak of wearing apparel, and other like articles of necessary use, every one of which, coarse and fine, is made elsewhere, and is a source of drain to the industry of this section. But look on your tables and see if your meat does not come from Tennessee; look at your plows and see if every mule that draws them is not bought of Kentucky; even the horses which draw your carriages come from there.

Many pursue a line of policy on this subject, the very reverse of their own interests, from a mistaken idea of what their true interest is; others do so from sheer inertness and a want of reflection; some from being deluded by maxims applicable to particular situations and necessities, and not capable of general application. The Island of Malta imports all its bread stuffs, and why? Because it is a rock, and incapable, from its want of soil, as well as size, to raise them. Is that the case here? England imports bread stuffs and yet prospers;—and what is the reason? By her gigantic power having, through a credit system of her own, made herself the heart of the monetary world, she can display an appearance of prosperity, in despite, and not by reason, of that deficiency, in the capacity of the realm, to produce provisions sufficient for its accumulated population. Some of the West India Islands, and some plantations on the Mississippi, do not raise their provisions, but the reasons which may be good there, do not hold here. We, to be prosperous, must make bread and meat plenty and cheap. Turn the question as you will, it resolves itself into this.

In a succeeding article, we discuss the question of raising our own meat, and endeavor to show that it is the present, as well as prospective interest of the farmer to do so. J. B. L.

Macon, Ga.

For the Southern Cultivator.

Can a farmer buy his meat cheaper than he can raise it at home?

It is a common place remark with a class of slip-shod sort of planters, that "a man can buy his meat cheaper than he can raise it." At some particular junctures, when corn is high and meat low, this may be momentarily the case, if cotton happens to bear a fair price at the time. Taken for a series of years, this maxim is devoid of truth, and ruinous to individuals and the country in its effects. And what guaranty has he that the supply of meat from abroad may not fall short, as has been the case this year with mules? And no circumstance tends more to bring about that result, than the late very low prices, which are calculated to dishearten the Tennesseean, and prevent his bringing the former quantity to market. This year meat has been unusually low, and that very fact may add 50 per cent. to its price another year, and the meat buying farmer will find himself at the mercy of the Tennessean. To reason by analogy this will very likely happen. Any one can recollect that in 1843, good mules sold here for $30 to $35, and the same description brought $75 this past winter. What safeguard has the planter who raises neither meat or mules, against these periodical revulsions in the market of those articles?—revulsions dependant on the laws of supply and demand, which his helpless situation prevents him from averting from his own door. A planter who raises corn, near a large market town, may sometimes make money by selling his corn at a high price, which usually happens once or so in a season, and buying his meat. But the great mass of farmers live at a distance from a market, and have no such advantages. But if even this one turns speculator and sells corn to buy meat, he will find, in an average of years, he will make but little by it.

Let us examine the question of meat-buying closely. Say two acres of land will produce a bag of cotton weighing 400 pounds; this, at five cents, will be $20. What would this same two acres of ground produce, if cultivated in corn and fed to four hogs of a year old? We have estimated that it produces 800 weight of seed cotton to the acre, according to the above calculation, and land which yields that much cotton will bring 40 bushels of corn. Well, that would be 40 bushels of corn, which, fed to four hogs of a year old, at the rate of ten bushels to each, would make each one weigh certainly 175 pounds net. Multiply this by four, and we have 700 pounds of pork as the result, which, at three cents per pound, is $21—a difference of a dollar against the theory of "it is cheaper to buy than to raise,"* with the additional advantage of placing the farmer above the contingencies of a short supply and high prices.

Since we began this article, in looking over our papers, the following apposite remarks of the Albany Cultivator, on the subject of the pork market, has met our eye, and we transfer it here as a corroboration of our suppositions. We had supposed, in the usual course of things, this fluctuation *might* take place, and it seems that in fact *it has taken place* sooner than we expected:—

"DEFICIENCY IN THE SUPPLY OF PORK FOR 1844.—We are not surprised at the falling off in the amount of pork slaughtered in the West last season. From 1838 to 1841, it is well known that an excitement, amounting almost to a mania, prevailed through the country in relation to hogs. Improved breeds were sought after with great avidity, and in many instances very high prices were paid, particularly for Berkshires.—The natural consequence of this excitement was, first, that unusual numbers of hogs were reared and fattened, and of course the pork market was glutted. The unprecedentedly low prices of pork in the western markets, for the years 1841 to 1843, proved almost ruinous to those farmers who relied on that article for their chief income. Many farmers were forced to sell their hogs for no more than a dollar and fifty cents per hundred, 'dead weight,' and in some instances for less. They could not stand such low prices, and hence followed the second result of the former

*Let practical farmers examine all the above calculations, and make such alterations as may suit the yield of their land, and accord with their experience, and they will find that we are not far from right in the main.

excitement, viz: the raising of but a small number of hogs, and the falling off in the quantity of pork killed in the western country last year. We see it stated in various papers that the amount packed at Cincinnati last year was less by one-third than for the year previous. At St. Louis it is said the decrease is still greater; and through the State of Illinois there is said to have been a falling off of from one-third to one-half. In Ohio the falling off was much greater, as we are informed, at the interior slaughtering places, than at Cincinnati. In the Scioto valley, for instance, where the number slaughtered at nine places in 1843 was 121,800, the number for 1844 is only 48,350. It seems probable, from present prospects, that pork will command at least remunerating prices the coming fall, and those farmers who had the foresight to see this, and have wisely provided themselves with a sufficient stock of a good breed of hogs, will be likely to reap their reward."

So we may expect an increase of price, for some time to come, and the same causes which have produced this reaction in Ohio, will probably develope themselves in Tennessee a year later, in time to affect the next winter's supply of pork here. Now let us suppose that the planter, who purchased his meat last winter at three cents, should have to pay five cents for it the next, and see how our calculation above will stand affected by it. The 700 pounds of meat at that increased price would be worth $35, which would be a difference of $15 against his anti-meat raising system. And while these serious changes are taking place, may there not be a decline in cotton?—Such things take place occasionally, as he is aware; and, instead of purchasing his meat with cotton at five cents, or, in other words, giving a pound of cotton for a pound of meat, may not cotton fall to four cents? In that case it makes the difference stand against his theory at $19, or very near one hundred per cent.

We trust that we have shown, that if at particular times, for a short period at best, the planter does well to buy his supply of meat, with the proceeds of his cotton and corn, in the main that plan is destructive of his own interests, and in a high degree prejudicial to the general welfare and prosperity of the community at large. The farmer is truly the bone and sinew of the country. His prosperity makes all others prosperous, and his ruin is succeeded by a destruction to all other callings. If, collectively, the farmers of a country pursue a correct policy, which results happily to themselves, the whole land smiles; if they pursue the infatuated course, heretofore followed in Georgia, the country is clad in the lugubrious raiment of sack-cloth and ashes. When will the farmers of Georgia pursue their true interests, and raise the dejected head of their beloved State? J. B. L.

Macon, Ga., April, 1845.

For the Southern Cultivator.

The Bommer Method of Making Manure.

Mr. Editor—At the request of a friend, who entertains perhaps too favorable an opinion of my practical knowledge of planting, I send you, for publication, the following remarks on my experiment on the Bommer method of making manure. It was no part of my purpose, at the outset, to publish anything in relation to this process, which I knew was already in the hands of many who were every way more capable of performing this public service. This will account for, if not excuse, that want of precision in the results of the experiment, which could alone render it of the slightest importance to scientific agriculture. Where this precision is wanting, my individual opinion must go for what it is worth.

In the latter part of 1843, I purchased the patent Bommer method of making manure, and, in January, 1844, I put up a heap 30 by 40 feet, and 6 feet high, composed of leaves, straw, a large proportion of which was of corn-stalks, which I watered for about six weeks, according to the printed directions which accompany the patent. During this period, the weather was extremely cold and dry, which is considered the most unfavorable state of the atmosphere, for fermentation or decomposition. On examination of the heap, I found the materials had very unequally decomposed; that the most solid matters, as the corn and cotton-stalks, were but slightly decomposed, while the less solid, such as straw, leaves, &c., were rapidly rotting, though not thoroughly decomposed. Into the lye, with which the heap had been watered, I put four barrels lime, thirty pounds saltpetre, and two two-horse wagon loads of fresh stable manure.

About the first of March, one half of the heap was hauled out, on one part of a field of worn land, the other part of which I manured with lot and stable manure, and planted the whole field in corn. The yield was, I think, about double the usual crop; and the best judges that saw the field pronounced that part manured by the Bommer manure decidedly the best. The other half of the heap was hauled out on part of a cotton field, otherwise unmanured. In the spring and first part of the summer, there were periods of protracted drought, and the product of manured lands, whether with cotton seed, stable manure, or Bommer's manure, was not what might have been anticipated. But the decided superiority of the Bommer manure, imperfectly rotted as it was, over the stable manure, was so marked that the slightest observation could not fail to detect the difference in the size and vigor of the stalks and ears. Its effects upon the cotton was no less decided; and though I did not weigh the product, I feel assured that it was increased by the Bommer manure at least one hundred per cent. over the *unmanured* part of the field.

In February, 1844, I put up another heap; of the labor and time employed on which, I am enabled to give a more specific account. I had fifteen hands and two wagons engaged in this work; the materials employed were pine leaves, straw, and corn-stalks, all in a dry state, much the largest portion being pine leaves. The site was cleared of trees and shrubs, by digging up their roots. The vat was excavated, and the grate constructed, and 500 wagon loads of material were put on, and all in readiness for watering in eight days.

This may give an idea of the labor necessary to putting up the first heap, though greatly exaggerated as to the time and labor to be bestowed on any subsequent heap—for full half the time and labor was consumed in clearing the trees, excavating the vat, and making the grate, which need nothing but slight repairs to keep them serviceable for years. On this last heap, I used ten barrels of lime, four loads ashes, forty pounds saltpetre, four bushels common salt, and about four loads fresh stable manure. From this heap, I hauled on a cotton field about 300 wagon loads of as fine, rich, well rotted manure as I have ever seen, and have manured for the present crop about thirty acres in drill, filling up the furrow with the manure. I have applied the lye to my garden vegetables, with the most happy effects. Under its application, beets and cabbage plants thrive beyond any thing in my former experience in gardening. It is, indeed, to this mixture, I ascribe the chief efficacy of the manure, and the absorption of the largest quantity of the compound is of the greatest importance to the fertilizing property of the manure. The frequent and thorough watering is therefore of indispensable necessity. Disappointment awaits the farmer who does not give this part of the process constant attention. To obviate as far as possible, this laborious part of the process, I have used a common plank pump, of three inches bore, made by a common carpenter with a hose made of cotton or osnaburgs, which should be oiled or painted. With these appliances, three able bodied hands watered the heap, after it was fully saturated, in three or four hours.

In conclusion, I have no hesitation in declaring my opinion, that a planter may manufacture as much of this manure in the year as he can haul out in the next spring; that the labor and trouble of the method, when once fairly under way, is scarcely beyond what is incident to making manure of any other kind; that the expense is trifling, in comparison with the returns of the outlay; and I heartily and honestly recommend it to every farmer and planter, who wishes to increase the product of his fields, and render their improvement permanent.

Yours, &c. William Byne.

For the Southern Cultivator.

Silk.

Mr. Camak:—In order to induce my brother farmers to plant less cotton and turn their attention to something else, I would inform them, through your valuable paper, that I have been raising silk in this county for the last six years, and have found it a profitable and interesting employment. So well satisfied am I that it is the best agricultural pursuit now followed, that I have just completed an extensive cocoonry, and planted out five acres more of mulberry trees; and I intend to increase my stock annually. I have all my cocoons reeled, made into sewing silk, dyed, and put up in skeins, by my own family; and I find no difficulty in selling it at a fair price.

I am prepared for reeling extensively; and would give a fair price for cocoons delivered at Savannah, or at the twenty or thirty mile station, on the Central Rail Road. For good cocoons, of the present year's crop, cured by exposure to the heat of the sun, (which is much better than steaming or baking in an oven,) from which all the double and soft ones have been picked, and the floss taken off, I will give two dollars and fifty cents per bushel. A first rate article would be worth something more.

I send you a few skeins of silk as a sample of what has been done, and of what, (with a little care and attention) might be done, by almost any farmer in the State.

Your ob't. serv't. Hugh Cassidey.

Bermuda Grass.

To the Editor of the Southern Cultivator:

Dear Sir—Your much esteemed favor of 24th Feb. was duly received; and the reason for my not answering it before this, was, first, I have been much of the time since from home, and secondly, you have asked me for information on a subject which I consider of more importance to the agricultural interest of our State than any other; and on which, if it can be given satisfactorily, the man who does it will deserve, not *only the silver cup*, but the thanks and gratitude of our whole community. Its importance, therefore, caused me to hesitate whether I could give you the desired information, as I have not yet satisfied myself fully whether to look upon *Bermuda Grass* as a friend or enemy, a blessing or a curse. You have asked me to give you, in detail, both my opinion of the value of the grass and my plan to get rid of it, when we want the land it occupies for other purposes. Now, if I could tell you satisfactorily how to accomplish the latter, without too much expense, (if indeed it can be killed at all,) then there would be no difficulty in saying, that this grass would be invaluable. Not so much for grazing, as Mr. Spalding states, or for hay, as Mr. Affleck says in your January number, as for the great benefit to our worn out lands, by putting them down in this grass, while not in hoed crops, to keep them from washing, and for giving them a sod of turf to supply the place of red clover. The ten thousand roots and runners, with considerable substance, (as one of the above named gentlemen states,) afford valuable organic matter, to be turned under, when the land is fallowed, previous to a hoed crop, which I have found much improves the soil, when you succeed in killing and causing these roots, &c. to be decomposed in the earth.

This brings me directly to the task of giving you my little experience in killing it, when the land is wanted for other purposes. Some four or five years since, I had a favorite four acre lot, which had been entirely overrun by this grass, so as to be rendered useless for any other purpose than grazing. I concluded to try my hand in killing the grass in this lot, if I did not in other now large growing patches on my farm. I prepared myself with Ruggles, Nourse & Mason's celebrated four-horse plow; put four strong mules to it, in April, turned the sod over, (better to have been done in the fall so as to have the benefit of the frost,) let it lie a month, then harrowed it well with a heavy iron-tooth harrow, then drilled and planted the common cow-pea three feet wide, and cultivated well. The peas grew finely; I should think, off the four acres, I saved twelve or fifteen tons good pea-hay, pulled up by the roots when the peas were ripening. I sowed the lot down in wheat as soon as the peas came off. I took from the four acres, without manure, over one hundred bushels of clean wheat. By this time, by means of the pea crop, which was large, and succeeded by a wheat crop, also very good, I had so shaded the sun-loving Bermuda that I could

hardly see any of its roots, much less the above-ground runners. So great was my supposed triumph, that I crowed largely over my fallen enemy, and talked much of its value among my neighbors, and told them that I did not dread it, but rather intended to court a still more intimate acquaintance with it. After the wheat crop came off, I manured but lightly, fallowed and put the lot in readiness for Ruta-Baga. In July I commenced sowing in drills. I am certain I took from these four acres, over three thousand bushels of the finest turnips I ever saw grow in any country. After the turnips came off, I saw, in many places in the lot, bunches of the Bermuda. I then planted the whole four acres in squashes, and made a fine crop for my hogs, and as fine a lot of Bermuda as I had at the beginning! So, I thought I had killed it, but found I was mistaken. I now think I did not pursue the rotation of overshading crops long enough, to kill every root in the ground.

I have no idea it can be killed in any other way than by overshadowing crops by those who have much of it, without too much expense. As to killing it by any kind of plowing, or planting hoed crops among it, this is utterly impossible, and particularly on our red stiff lands, such as mine are. It is a great deal easier to manage it in light and sandy lands; though even in these, you do not exterminate it, but by constant culture you may keep it under so as to make crops.

I am now just commencing to try a new method of destroying this grass, and that is, by a rotation of peas and Jerusalem artichokes, or perhaps peas, wheat, and then artichokes. I have, from what I have seen of the artichoke, great faith in its being a valuable smotherer, for I would as soon try to drown a fish by throwing him in the water, as to kill Bermuda Grass by never so much working in the sun. Besides, if this will kill it, you do so with a most valuable crop for swine.

I have tried various other methods to kill this grass, with little or no success, and which it is needless now to mention, as to my mind there is no way so likely to be successful as by overshadowing crops, and that in succession for some two or three years; and when we shall be able to manage it, (if, indeed, we shall ever be,) it will be looked upon as a great blessing, which I must think a kind Providence intended it to be.

JOHN CUNNINGHAM.

Greensboro, (Ga) March 20, 1845.

Bowling Green Agricultural Society Fair.

The Annual Fair of the Bowling Green Agricultural Society will take place at Bowling Green, on Friday, the last day of October next, when the following premiums and honors will be awarded:

For the best acre of upland corn, a silver cup, value.....$3 00	Best bull, cup.....$3 00
2d best acre.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best acre of low-ground corn, cup.....$3 00	Best cow, cup.....$3 00
2d best acre.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best acre of wheat, cup.....$3 00	Best two year old heifer, cup.....$3 00
2d best acre.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best acre of oats, cup.$3 00	Best spring calf, cup..$3 00
2d best acre.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best acre of sweet potatoes, cup.....$3 00	Best boar, cup.....$3 00
2d best acre.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best half acre of turnips, cup.....$3 00	Best sow, cup.....$3 00
2d best half acre..1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
For the best three year old colt, silver cup..$3 00	The heaviest hog under eighteen months old, in proportion to age, cup.....$3 00
2d best colt.....1st honor	2d heaviest.....1st honor
3d best.....2d honor	3d heaviest.....2d honor
Best two year old colt, cup.....$3 00	Best conterpane, cup.$3 00
2d best.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best spring colt, cup..$3 00	Best eight yards of domestic jeans, suitable for gentlemen's wear, cup.....$3 00
2d best.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor
Best brood mare, cup $3 00	Best article of Negro clothing, cup.....$3 00
2d best.....1st honor	2d best.....1st honor
3d best.....2d honor	3d best.....2d honor

The Society have set apart ten dollars to be awarded by their committees, to articles manufactured by the ladies, not enumerated in their premium list, such as capes, collars, caps, &c. or any fancy article made by a lady.

JOHN W. MOADY, *President.*
William Jewell, Secretary.

Farmers' Convention.

MILLEDGEVILLE, 31st March, 1845.

The Agricultural Convention of the State of Georgia assembled this day at 12 o'clock, M., at the Court-house in this city. Delegates from the counties of Morgan, Cobb, Paulding, Putnam and Baldwin, appeared and took their seats; when, for the purpose of organization, on motion of Maj. Wm. Y. Hansell, a delegate from the county of Cobb, Col. Herschel V. Johnson, of Baldwin, was called to the Chair.

The Chairman having announced that he was prepared to receive any proposition which the Convention had to make, Mr. Turner, from the county of Putnam, offered the following resolution:

Resolved, That His Excellency the Governor of the State of Georgia for the time being, be chosen President of "the Agricultural Association of the State of Georgia"—which was adopted.

It was *resolved*, on motion of Mr. Grantland, from Baldwin, that the Chair appoint a Committee to wait upon his Excellency, Gov. Crawford, and inform him of his appointment.

Whereupon the Chair appointed Messrs. Grantland, Turner and Harris that Committee.

The Committee having informed Gov. Crawford of his appointment, and conducted him to the Chair, after a few remarks relative to the objects of the Convention, he announced the body ready to proceed to business.

On motion of Mr. Harris, it was

Resolved, That Dr. John R. Cotting be appointed Corresponding Secretary, and Benj. T. Bethune, Esq., Recording Secretary of the Agricultural Association of the State of Georgia.

On motion of Mr. Jones, of Paulding, it was

Resolved, That the President appoint a Committee of five, whose duty it shall be to draft a Constitution for the Association, and to recommend to the Convention the various subjects which shall be appropriate for its consideration. The Committee named by the Chair, were Messrs. Jones, Turner, Johnson, Hansell and Spear.

The Convention then adjourned till four o'clock, P. M.

FOUR O'CLOCK, P. M.

Convention met pursuant to adjournment.

Judge Jones, Chairman of the Committee to draft a Constitution, &c. reported the following:

Art. 1. This Society shall be known by the name of the "*Agricultural Association of Georgia*," and shall be composed of the members of all Agricultural Societies or Associations which are, or shall be hereafter formed in this State; and its annual meetings, which shall be held on the second Monday of November in each year, in the city of Milledgeville, shall consist of a Convention of such delegates as each of said Societies shall send.

Art. 11. Its officers shall consist of a President, who shall be the Governor of the State for the time being, and as many Vice-Presidents as there shall be Agricultural Societies or Associations in the State; the several Presidents of which shall be ex-officio Vice-Presidents of this Association—Recording and Corresponding Secretaries—the Recording Secretary acting ex-officio as Treasurer.

Art. III. The object of this Association shall be to promote, by all proper means, the advancement of the Agricultural and domestic economy of the State in all their various departments.

Art. IV. At each annual meeting, there shall be an Executive Committee of five, appointed to receive the reports of such committees as this Association may appoint and such other matter as may be refered to them through the Corresponding Secretary, and to perform such other duties as may be required of them, or as may properly fall within their province.

Art. V. The funds of this Association shall be composed of such moneys as may be raised by voluntary contributions.

Art. VI. This Constitutionmay be altered or amended by a vote of the majority of the members present at any annual meeting.

Which report was received and adopted.

The Committee further recommend the appointment of the following committees:

1st. A Committee of——to report to the next annual meeting on the subject of the Agriculture of Georgia.

2. A Committee of—— to report on Grains.

3. A Committee of—— to report on Stock.

4. A Committee of —— to report on such plants as may be profitably introduced, and which are not now cultivated.

5. A Committee of—— to report on manures.

The Convention approved of the recommendation of the Committee, and on motion, it was *Resolved*, That the various blanks be filled by the Chair with the number three.

The President then stated, that, as it was necessary he should know the names of gentlemen composing the different Agricultural Societies in the State, to enable him to make judicious appointments, the committees would not be appointed until the various societies had been heard from.

Mr. Johnson offered the following resolution:

Resolved, That the Corresponding Secretary write to the respective Agricultural Societies of this State, informing them that their members are constituted members of this association, and that their respective Presidents are ex-officio Vice Presidents of the same; and that he request the said societies to furnish him with a full catalogue of their members, to the end that they may be entered on the records of this association, in the event of their being willing to become members thereof—which was adopted.

The following resolution was also adopted:

Resolved, That we recommend to the several societies of this State, to take into consideration the propriety of recommending to the next Legislature an appropriation for the purpose of procuring seed and grains of various kinds from different countries, for distribution among the various Agricultural Societies, and to report the result of such deliberation to the next annual meeting of this association.

The Association then adjourned *sine die*.

GEORGE W. CRAWFORD, *President.*
Benj. T. Bethune, Recording Secretary.

Cobb County Agricultural Society.

Pursuant to a previous notice, a large and very respectable portion of the citizens of Cobb assembled at the Court House in Marietta, on the 25th ult., with the view of organizing an Agricultural Association.

On motion, Hardy Pace and James Lemon, Esq's., were called to the chair, and Andrew J. Hansell, Esq., requested to act as Secretary.

The meeting was first addressed by Hon. John A. Jones, a delegate to the Convention about to assemble in the city of Milledgeville and *en route* to that point, in a highly interesting speech. H. R. Foot, Esq., was next called out, who ably discussed the propriety of an efficient organization of such a society, and the imperative necessity of an agricultural education. Jas. Lemon, Esq., one of the Chairmen, made an appeal to his fellow farmers of Cobb.

Col. Chas. F. M. Garnett, from the Committee to draft a constitution, &c., reported a constitution, which was unanimously adopted. The constitution was then signed by a number of our citizens; and on motion of Col. Garnett, the Society then proceeded to the election of its officers for the present year. On counting out the ballots, it appeared that the following gentlemen were unanimously chosen:

C. J. McDonald, President.

Vice-Presidents—H. R. Foote, Sam'l. Young, Wm. Harris, T. M. Kirkpatrick, Jas. S. Bulloch, Jas. Lemon, Hardy Pace.

William P. Young, Treasurer.

Andrew J. Hansell, Secretary.

On motion, Resolved, That Maj. Wm. Y. Hansell, be and is hereby appointed our delegate to the approaching Agricultural Convention, to be holden in the city of Milledgeville, on Monday the 31st ult., and requested to represent our Society in that body, which was unanimously agreed to.

On motion the Society then adjourned, subject to the call of the executive committee.

HARDY PACE, } *Ch'n.*
A. J. HANSELL, *Sec.* JAS. LEMON, }

Agricultural Society.

The Barbour County Agricultural Society met in the Town Hall, Eufaula, Ala., on the 15th March; the President, Col. McDonald, in the chair, John Gill Shorter, Esq., Secretary, pro tem.

The committee appointed last meeting to revise the constitution of the society, reported a substitute, which was adopted.

John A. Calhoun, Esq., Dr. C. Battle, and B. Gardner, Esq., were appointed a committee to draft by laws for the society, and to report the same to the next meeting.

Standing committees, to examine and report on crops, horticulture and improvement in mechanism, were appointed by the President, as follows:

To examine crops below Eufaula, Gen. R. C. Shorter, Mr. Wm. Abney, Mr. John W. Raines.

To examine crops above Eufaula on the river, Major Thomas Flournoy, Dr. C. Battle, Mr. A. McGehee.

To examine crops on the Barbour Creek, Mr. William DeWitt, Mr. James Tucker, Mr. Treadwell.

To examine crops on the Cowikee Creek, John A. Calhoun, Esq., Dr. A. P. Crawford, Gen. Wm. Wellborn.

Committee on Horticulture, John Gill Shorter, Esq., Mr. Wm. S. Paullin, Dr. William H. Thornton.

Committee on Mechanic arts, Z. J. Daniel, Esq., Mr. E. C. Holleman, Mr. W. Archer.

Messrs. B. Gardner, J. G. L. Martin and Thos. Cargile, were appointed a committee to select a suitable person to address the society at its next meeting.

On motion, it was ordered that the President also appoint four persons to discuss, at the next meeting, the following question: "What are the benefits to be derived from Agricultural Societies?" Messrs. Buford, Hemphill, Calhoun and J. G. Shorter were appointed debaters.

A letter from Dr. Richardson, to the President, was read, on the culture of cane and the manufacture of segars, and a sample of sugar raised by Dr. R. in Barbour county, shown to the society.

The society then adjourned to meet again in the Town Hall on the second Wednesday in May, the day of the Horticultural fair.

A. MCDONALD, President.
JOHN GILL SHORTER, Secretary *pro tem.*

Agricultural Meeting.

In pursuance of a previous notice a meeting of the Barbour County Agricultural Society was held in Glenville on the 22d inst, when, on motion of Major Denard, Col. A. McDonald was called to the chair, and George D. Conner was requested to act as Secretary pro. tem.

The Chair explained the intention of the meeting to be, to submit to the consideration of the citizens of Glennville, a hearty co-operation with the Barbour County Agricultural Society in its objects to improve and develope our farming resources, and of giving them the opportunity of adopting the new constitution of the Society, which was then read. On motion of Dr. Richardson, the constitution was adopted by a unanimous vote; an opportunity was then given for the admission of members under the constitution, and twenty-two additional names were announced.

The following gentlemen were appointed committees to examine crops and their condition, &c. in the vicinity during the ensuing season, and report at the next regular meeting of the Society.

1. On the Cowikee Creek, Dr. Dubose, Col. Sanford and Massalon Glenn.
2. On the Hachachubee Creek, Dr. Richardson, Major Denard and J. B. Baird.
3. In Browder's neighborhood, M. A. Browder, Malachi Ivey and Nathaniel Roach.
4. Glennville neighborhood, W. H. Owens, Dr. J. G. Byrd and Richard T. Morrison.

Committee on Horticulture, Dr. George D. Conner, A. S. Glenn, J. G. Conner, Thomas Denard and Dr. Flake.

Maj. Dent and Col. Ott were appointed a committee to examine the crops on the upper part of the South Cowikee, with power to appoint some other farmer to act with them.

After the regular business of the meeting had been disposed of, the President entertained the meeting in an appropriate manner, in explaining his views on the importance of well organized societies; their importance at the present time of the depressed price of cotton; the advantage of patronizing agricultural papers; the expediency of devoting special attention to the quality as well as quantity of our chief staple. The address abounded with most excellent suggestions relative to a well regulated system of farming, and was delivered with a zeal worthy of the occasion. It was listened to with interest, that gave evidence that it was highly appreciated by a larger meeting than common on such occasions.

Fifteen dollars were immediately handed in by way of a commencement in getting up a Fair next fall.

Glennville, Ala., March 22, 1845.

Breaking Young Cattle.

The people of New England, and none more than those of Massachusetts, have always been celebrated for the breeding and management of oxen, and as the following plan, from the pen of *Mr. Buckminster*, the enlightened editor of the Massachusetts Ploughman, appears to us to contain much good sense and sound philosophy, we commend it to our readers:

"It is sport, rare sport, for boys to yoke young steers, and fret them, till they are tame; and tire them down, till they are tame; to whip them hard for obstinacy---for moving too fast or too slow. Boys will teach them a bushel of tricks sooner than a peck of good manners. Boys must not handle steers till they have been handled by men; and men have not all philosophy enough to make steers kind and obedient.

There is not so much risk run in breaking steers as in tutoring colts. The ox is so patient he "will endure all things," even ill tutoring. In the yoke, in the centre of a strong team, he must go, will ye nil ye, and in time he will think it prudent to draw a moderate load rather than feel the lash or the goad.

But what a vast difference you find between oxen that have been properly broken and such as have loosely "borne the yoke in their youth," and had their own way at a hill or in the mire? Can they back a loaded cart, or will they know your voice at a plow?

Ill tutored oxen will fail you in your utmost need. They are as bad as untrained men at the raising of a broad side of a barn; they never draw even, and one is not ready to put forth his strength till his yoke fellow has exhausted all his store. Then you leave your loaded sled in the woods and go for the mare; or you unlade a part and hie home in a pet.

Oxen should never know but that they can draw any load you put them to, and they will never suspect it under a perfect teamster. He will never let them draw when he finds the load quite too heavy, and by crying out to them to stop when they cannot go he persuades them that they are stopped by his command alone.

Steers may be yoked at a very early age. When it is convenient, shut them up in a shed or strong pen, and gently place a light yoke on them there. Do not attempt to force them to march now, but wait till they have become used to this burthen. Feed them with something a little better than every day fodder, and satisfy them that you intend no harm. If your shed is large, it will be prudent to pass a rope around the hind part of their bodies to prevent their turning their yoke upside down, and making the near one the off ox. A rope will prevent this, for it will keep their hips as near to each other as their necks are. Some tie their tails together for this purpose; but a rope is better.

When your steers have become a little used to the yoke, you can put a chain on and let them be used to the clanking of the links. Chain them fast to a post in your shed, and let them feel that this front chain and the yoke are stronger than they are. They may stand for half a day chained fast, and you need to look to them only occasionally.

Now you should unyoke gently and let them have their liberty, evidently by your own consent. On the morrow, yoke them again in the same place and with the same care. Then yoke up your oxen, and driving to the shed, make fast your steers to the oxen instead of the post. Let the whole four stand awhile, that the steers may see no harm is intended.

Soon you may urge them forward close after the oxen, and without using a whip. Let them follow round and round the yard, chained to the oxen, never putting them to draw till they have learned to follow without fear.

After this exercise you can bring a light sled, or a pair of wagon wheels and tongue, and gently fasten your steers on this tongue. Let all stand a few minutes; then move forward gently, not to terrify the young fellows too much on finding a moving pole between them, and a pair of rolling wheels behind. Keep them in gear four or five hours to-day, having a rope on the horn of the nigh one to make both follow directly after the oxen.

In this way you can use your steers to follow your oxen without striking a single blow. For the only cause of obstinacy which we so often find in steers, is *ignorance* and *fear*. They know not what you would have, they fear giving offence, and they will prefer your lashing and beating to any motion they can make. You know this is the case, for, unyoked, you can drive one, or two, or a dozen, through any part of your field, and no one thinks it advisable to stand and endure the lash in preference to moving.

But you must teach your steers to lead as well as to follow your oxen. This requires skill, to prevent bad habits. When first put to lead they will incline to run from you, unless you have a rope on the near horn. But you will soon habituate them, *if you avoid beating*, to march straight forward; and they will suffer you to advance and come to their heads without attempting to sheer off, if they find you friendly. In a snow path you will find it more easy to make them tractable than in a plow field.

It is quite important that young cattle should be loaded so light that they can overcome all obstructions without great effort. They should not suspect that any load can stop them. If they have not been set, and whipped, and bothered, by vicious teamsters, you will find them ambitious to do all in their power for you on rising a hill, or in miry carting. You will command their whole strength without striking a blow, and you will be more sure of getting out of the mire than by the use of all the whips you can command.

But your cattle will not go; nor will they stop when you desire, unless you use good language to them; not Greek, or Latin, or Hebrew, but good plain English. You may use the Hebrew well enough, provided you understand it, and provided you alone are to be the driver. But if you do not; or if you intend that others, who know nothing but English, shall drive your oxen occasionally, you will find the "English Tongue" the "Only Sure Guide," as Perry said of his spelling book, when it treated of that tongue.

Those who have heard the language of various drivers will not think this an unimportant rule. Oxen must be more knowing than lads in Greek to get a clear idea from the sounds made in their ears by their uncivil drivers. The same rigmarole, harum scarum, *hi, hoi, whoi*, who-hay, is used whether the team is to move or to stop---to haw or to gee---to keep quick time or to back the load; and the astonished ox---the *native* ox---must wait till the goad quickens his ideas, or till the butt end of the handle on his nose has planted the seed for a wen, to disfigure his face, cause him pain, and shorten his life.

Should not the doctrine of *transmigration* be taught to cruel masters? Who would thus abuse an ox if he himself is to take his turn in the yoke and under the goad-stick?"

Horticultural Outline.

AN OUTLINE of the first principles of HORTICULTURE, by JOHN LINDLEY, F R. S. &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.—[CONTINUED.]

V. LEAVES.

126. Leaves are expansions of bark, traversed by veins.

127. The veins consist of spiral vessels enclosed in woody fibre; they originate in the medullary sheath and liber; and they are connected by loose parenchyma (7) which is full of cavities containing air.

128. This parenchyma consists of two layers, of which the latter is composed of cellules perpendicular to the cuticle, and the lower of cellules parallel with the cuticle.

129. These cellules are arranged so as to leave numerous open passages among them for the circulation of air in the inside of a leaf. Parenchyma of this nature is called *cavernous*.

130. Cuticle is formed of one or more layers of depressed cellular tissue, which is generally hardened, and always dry and filled with air.

131. Between many of the cells of the cuticle are placed apertures called *stomata*, which have the power of opening and closing as circumstances may require.

132. It is by means of this apparatus that Leaves elaborate the sap which they absorb from the alburnum, converting it into the secretions peculiar to the species.

133. Their cavernous structure (129) enables them to expose the greatest possible surface of their parenchyma to the action of the atmosphere.

134. Their cuticle is a non-conducting skin, which protects them from great variations in temperature, and through which gaseous matter will pass readily.

135. Their stomata are pores that are chiefly intended to facilitate evaporation; for which they are well adapted by a power they possess of opening or closing as circumstances may require.

136. They are also intended for facilitating the rapid emission of air, when it is necessary that such a function should be performed.

137. The functions of stomata being of such vital importance, it is always advisable to examine them microscopically in cases where doubts are entertained of the state of the atmosphere which a particular species may require.

138. Leaves growing in air are covered with a cuticle.

139. Leaves growing under water have no cuticle.

140. All the secretions of plants being formed in the Leaves, or at least the greater part, it follows that secretions cannot take place if Leaves are destroyed.

141. And as this secreting property depends upon specific vital powers with the decomposition of carbonic acid, and called into action only when the leaves are freely exposed to light and air (279,) it follows that the quantity of secretion will be in direct proportion to the quantity of Leaves, and to their free exposure to light and air.

142. The usual position of leaves is spiral, at regularly increasing or diminishing distances; they are then said to be alternate.

143. But if the space, or the axis, that separates two leaves, is reduced to nothing at alternate intervals, they become opposite.

144. And if the spaces that separate several Leaves be reduced to nothing, they become verticillate.

145. Opposite and verticillate Leaves, therefore, differ from alternate Leaves, only in the spaces that separate them being reduced to nothing.

How to make Soap.

MESSRS. EDITORS—If you think the following article worthy of an insertion in your valuable paper, it is at your service. I have seen a great many well written articles on Agriculture, Cookery, &c. &c, but as I do not recollect of seeing any thing written on "making Soap," I will give you the following, which is the result of *years* of experience:

First, set up your tub as usual, with sticks and straw, and then put your lime (slaked) on the straw to the depth of three or four inches—then take a long stick that will come a few inches above the top of the tub—wind a hay rope around the stick, nearly its whole length—let the stick go through the tub two or three inches, then you can draw your ley without putting your hands into it underneath. Put your grease into the kettle, and turn in about two quarts (or enough to cover the bottom of the kettle) of your strongest ley. Boil a few minutes, then turn in a little more ley, and continue to turn in as the ley boils over, until your kettle is about two thirds or three quarters full, when you can fill up the kettle, and after skimming the contents well, dip out and empty it into the barrel. Put in two pounds Rosin to one barrel Soap. If your ley is of sufficient strength, you will be *sure* to have *good* Soap. I have heard people complain a great deal that they did not have "good luck" in making Soap. Their ashes were not good or not made from good wood, or something or other. But if the above directions are carefully followed, I can assure them that they will have no reason to complain of "poor luck," or any thing of the kind.

N. B.—Clear grease does not require more than ten minutes boiling, but where there are bones, it takes longer time. Some people put lime in the middle of the cask or tub, but the main use of lime is to strain the ley, and make it pure—therefore it should be put on the top of the straw at the bottom of the tub. AN OLD HAND.

Grey, February 28th, 1845.

Grinding Grain for Animals.

The trouble and expense of grinding or crushing grain for animals, are generally much less than the saving that is made by this operation. Most animals eat their food, especially that which they prefer, rather greedily, and frequently swallow down grain without chewing or even cracking; this passes the animal without digestion, as is evident to any observer who has the care of stock, and fowls often live well upon the grain that thus escapes decomposition; and where such grain is suffered to remain in the manure, it is often seen growing luxuriantly, a living evidence of the waste in such a mode of feeding.

Economy is of the highest importance in every department of rural affairs. Some farmers may say that they cannot afford the trouble and expense of grinding grain. Then, of course, they cannot afford to pursue a more expensive way of feeding. As a matter of convenience many persons feed grain whole, without examining the subject, or once thinking how much they lose by it. Let such reflect a little, and they may be disposed to try the effect of ground food and judge of the result from experience.

Grain has grown after passing through the stomachs of horses, cattle and hogs. Sheep grind their food better; and fowls swallow coarse gravel, which, in the gizzard, serves the purpose of *mill-stones*, in grinding grain and other hard food, to powder, and the gravel is ground in turn, and its place supplied by a fresh lot.

Besides the saving of grain by grinding, as appears from its being better digested, as well as from numerous experiments, it is evidently better for the health of animals to have such food as will be readily digested, requiring less labor in this process, according to the views of a shrewd farmer who dismissed a hand who was a great eater, as he observed, it would require all his strength to digest his food.

At some of the agricultural warehouses are machines for grinding grain, which may be operated by a man or boy; and in the winter season, labor can frequently be applied to this purpose with very little inconvenience. One hour in this way, in a more leisure season, may save two hours in raising grain, in the busy time of planting, haying or harvesting.

Seed Wheat.

MESSRS. EDITORS:—We are told, that, in the Island of Jersey, (England,) where the farmers sell their *produce* and live upon the *refuse*, it is customary for them to tie their wheat in small sheaves, and by striking each twice or thrice across a barrel while lying on its side on the floor, a superfine sample of wheat is obtained for market, after which the sheaves are thrown by, to be clean thrashed in the evenings of winter by lamp light.

I have just met with the account of a farmer in Vermont, to whom his neighbors resorted for the purpose of securing seed wheat of superior quality; very fine in appearance, remarkably productive and of early maturity; he readily commanded three dollars per bushel, when the price of wheat was a dollar and a quarter, calling it the red and genuine *Barrel wheat*. But the secret was at last discovered; he used, before thrashing his wheat, to select the best sheaves, and striking them over the side of an empty barrel as it lay on the floor, three or four times before laying them down to be clean thrashed, he obtained in this very simple way a very superior seed, wheat, which the whole county coveted at a double price. Thus the largest and ripest kernels were separated and collected without labor or difficulty, and a profitable business was carried on, until his neighbors discovered how to make "Barrel wheat" for themselves. EDMUND LAWRENCE.

Newark, N. J.

VALUABLE AND SIMPLE MEDICINE.—When food is taken that causes oppression, the best remedy is hot water in which the rind of old cheese has been grated, to be drank freely. This simple remedy ought to be in the possession of every family, as it will generally afford speedy relief. Some fifty years since, a young lady died in this town from the effect of eating fruit. A post mortem examination was had, and some experiments were made; nothing was found to have so good an operation upon the contents of the stomach as the grated cheese rind. Soon after another lady was placed in a similar dangerous situation from the same cause. Her medical attendant prescribed the above remedy, and immediately relief was obtained. The medicine became popular with the past generation, and a lady of that age wishes us to publish it to this and succeeding generations.—*Portsmouth Journal.*

DRESSING WOUNDS AND ULCERS.—Dr. Langier's new method consists in applying on the surface of the wound or ulcer a solution of gum arabic, and on it a bit of goldbeater's skin; thus dressed, a wound an inch in diameter was reduced in the space of eight days to one-third or one-sixth of an inch in extent. Cicatrisation took place so rapidly that the granulations, covered with a thick epidermis, were as numerous and visible as before, but could be touched without causing pain. A wound produced by amputation of the breast highly inflamed about four and a half inches in length, and one and a half in breadth, under this treatment healed rapidly, and purulent secretion did not take place. He proposes applying this method to a wound left by amputation of the thigh.—*Medical Times.*

Ornamental Gardening.

In Colman's late writings on European agriculture, we find the following:—

"The cultivation of flowers and shrubs and vines is a remarkable and prominent feature in the landscape of England; and a circumstance which has given no little gratification to my national pride, has been the profusion of American plants, which are seen in the shrubberies and plantations and pleasure grounds, both public and private. Green-houses and conservatories are almost universal in the country where any thing like a garden exists; and the better class of houses surrounded and adorned with a great variety of flowering shrubs and plants, presenting through the season a charming succession of gay and brilliant ornaments. Even the laborer's humble cottage, too seldom, I am compelled to admit, any thing but a picturesque object, will occasionally have its ornamental shrubs adorning its doorway, and the ivy hanging its beautiful tresses over its window, forming as it were a mirror set in a frame of the richest green. The village of Marr, in Yorkshire, not far from Doncaster, and the village of Edensor, in Derbyshire, near Chatsworth, and the village of Lord Brownlow, in Lincolnshire, the best built, and by far the handsomest villages I have yet seen in England, to cottages of an excellent and picturesque construction, add those beautiful rural embellishments of vines and shrubs and flowers, and at the first sight compel a reflecting mind to admit the moral influence of such arrangements upon the character and manners of their inhabitants.

"I have said and written a great deal to my countrymen about the cultivation of flowers, ornamental gardening and rural embellishments; and I would read them a homily on the subject every day of every remaining year of my life, if I thought it would induce them to make this a matter of particular attention and care. When a man asks me what is the use of shrubs and flowers? my first impulse is always *to look under his hat and see the length of his ears.* I am heartily sick of measuring every thing by a standard of mere utility and profit; and as heartily do I pity the man who can see no good in life but in the pecuniary gain, or in the mere animal indulgencies of eating and drinking."

LIGHTNING AND MANURE.—The U. S. Gazette says, it has been discovered in England that electricity, real lightning, conducted by wire to the earth, greatly promotes vegetation, and hence many persons are enriching their grounds by this new stimulant. We hope good will come of it. This generation is certainly fulfilling its destiny. It is becoming the "utilitarian age" with a vengeance, which brings down from the clouds the lightning of heaven (*eripuit fulmen*) to manure the corn fields, substituting Jove's dread lightnings for stable manure. The guano trade will be broken up entirely, and a tempestuous season, with vivid lightning, will be worth forty muck heaps and stable yards.

And yet it is probably true, that lightning can be made to promote vegetation; that it can be conducted to the required spot, and made subservient to the desired object—and if so, man has another cause of gratitude to the giver; for he may now lay his head upon the main lightning, and render it not only innocuous, but directly and visibly useful. Let him, in the use of the element, not forget Him,

"Whose hand the lightning forms,
Who heaves old Ocean, and who wings the storms."

VOL. III. AUGUSTA, GA., JUNE, 1845. No. 6.

A BRIEF HISTORY OF THE SILK CULTURE IN GEORGIA.

By the Rev. WILLIAM B. STEVENS, of the University of Georgia. [From Harris's Memorials of Oglethorpe.]

One of the principal designs which influenced the settlement of Georgia, was the hope of thereby creating a silk-growing province, where that material, for which England had so long been indebted to France, Italy and China, could be produced in this colonial dependency.

As early as 1609, the subject engaged the attention of the adventurers to Virginia, and in a pamphlet, called "Nova Brittania offering most excellent fruites by planting in Virginia," published that year, the writer says:—"there are silke-wormes, and plenty of mulberie trees, whereby ladies, gentlewomen, and little children, (being set in the way to do it,) may bee all imploied with pleasure, making silke comparable to that of Persia, Turkey, or any other." In 1650, Mr. Samuel Hartlib published a work entitled "Virginia Discovery of Silk Wormes, with their Benefits," in which he endeavored to show that the raising of silk was a thing very practicable in Virginia, and even asserted that as a staple, it might be made superior to tobacco, in which opinion he was confirmed by the judgment of several others. That they made some advances in this culture, is evident from the fact that the coronation robe of Charles II., in 1660, was made of silk reeled in that colony, and even so late as 1730, three hundred pounds of the raw material were exported from Virginia. Tobacco, however, soon assumed and maintained the ascendency, to the exclusion of this more useful and beautiful produce.

In 1703, Sir Nathaniel Johnson introduced the silk culture into South Carolina, but the astonishing success which rewarded the casual introduction of rice into the plantation, about eight years before, precluded a just interest in the undertaking, and as a public and recognised commodity it soon came to nought, though several persons, more for amusement than profit, still gave their attention to it; and as late as 1755, Mrs. Pinckney, the same lady to whom the province was indebted for the first cultivation of indigo ten years before, reeled sufficient silk in the vicinity of Charleston to make three dresses, one of which was presented to the Princess Dowager of Wales, another to Lord Chesterfield, and the third, says Ramsay, who narrates the circumstance, "is now (1809) in Charleston in the possession of her daughter, Mrs. Horrey, and is remarkable for its beauty, firmness and strength."

But notwithstanding these failures and the known difficulty of introducing a new branch of agriculture into a country, as was evidenced by the compulsion which was necessary by Henry IV. to introduce it into France, against the united voices of the merchants, traders, and even in opposition to the Duke of Sully, and also the indifference manifested in England, notwithstanding the able proclamation of King James on the subject, commending its cultivation; the Trustees for the settlement of Georgia determined to make one more effort, which, if successful, would enrich both the province and the mother country. The views which they entertained, however, of making Georgia supplant every silk-growing country, were extravagant and erroneous; they expected, in fact, to supply all Europe, and to produce an article of equal strength, beauty and value, with any made on the Continent. The Piedmontese, thought they, who pay half their silk for the rent of the mulberry trees and the eggs of the worm, or the peasants of France, burdened with political difficulty and stinted for conveniences, could not cope with the settlers of Georgia, where the mulberry trees (morus alba) would grow in the greatest luxuriance, where timber for their fabrics was no expense, where room was abundant and the reward sure. By this transfer, in addition to a direct saving to England of over £500,000, which she paid for this article to foreign countries, twenty thousand people were to find employment in reaing it in Georgia, and as many more at home in preparing it for market

Among the first emigrants who sailed with Oglethorpe from England in November, 1732, was Mr. Amatis, from Piedmont, who was engaged by the Trustees to introduce the art of silk-winding into the colony, and who, for that purpose, brought with him several Italians and some adequate machinery. White mulberry trees were planted in a portion of land on the eastern border of the city, called the Trustee's garden; eggs were hatched, and silk spun "as fine as any from France or Italy." They soon, however, came to a mutual rupture, and the whole process was for a time suspended by the treachery of those employed, who broke the machinery, spoiled the seed, destroyed the trees, and then escaped to Carolina. Sufficient, however, had been wrought to test its value, and they were not discouraged by this inauspicious commencement. The Trustees still adhered to their design, and the more effectually to advance it, required of every settler that there should be on his grant, ten mulberry trees to each acre.

Mr. Camuse and his wife, both Italians, with their two children, and two other individuals, were now entrusted with this business, in which they were continued six years; the two first at a salary of £60 per annum, and the four last at £100, besides the rent of a dwelling house and garden.

In June, 1734, Gen. Oglethorpe carried eight pounds of raw silk, the first produced in Georgia, to England, which was followed by a small trunk full of the same article, on the 2d of April, 1735, and after being made into orgazine by the engine of Sir Thomas Lombe, at Derby, who said that it "proved exceedingly good thro' all the operations," was sent up to London on the 14th of August, 1735, when the Trustees, together with Sir Thomas Lombe, waited on her Majesty Queen Caroline, and exhibited to her the elegant specimen of Georgia silk. The Queen selected a portion of this parcel to be wove into a pattern, and being again waited on by these gentlemen and Mr. Booth, the silk weaver, on the 21st of September, she expressed "a great satisfaction for the beauty and fineness of the silk, the richness of the pattern, and at seeing so early a product from that colony;" and to express her pleasure at such a favorable result, a complete court dress was made from it, and on His Majesty's next birth day, she appeared at the levee in a full robe of Georgia silk.

On the return of Oglethorpe, in 1735, he renewed his endeavors to bring it into active operation. For the purpose of obtaining a sufficient quantity of seed, he allowed no silk to be reeled that year, but let the worms deposit their eggs. He required, also, that the Italian women should teach a number of the colonists, and thus render general the knowledge they could impart. The Saltzburgers at Ebenezer were the most forward to adopt his views, and in March 28, 1736, Rev. Mr. Bolzius gave one tree to each inhabitant as a present from Oglethorpe, and two of his congregation were instructed in the art of reeling, by Mrs. Camuse. But though Oglethorpe gave Mr. Bolzius trees, silk worms, and a book of instructions, yet he confesses that he felt no interest in the business, nor inclination to pursue it.

In July, 1739, Mr. Samuel Augspourger carried over a parcel of raw silk which he received from Mr. Jones, the Trustee's store keeper in Savannah, and which was declared by eminent judges to be "equal to any Italian silk, and worth full twenty shillings per pound."

On May 11, 1741, Mr. Bolzius in his journal states that twenty girls, during the last two months, succeeded in making seventeen pounds of cocoons, which were sold on Friday last at Savannah for £3 8s. During this year, General Oglethorpe advanced to Bolzius £5, for procuring trees, for which sum he obtained twelve hundred, and distributed twenty-two to each family in his parish.

On May 1, 1742, fourteen pounds and fourteen ounces were sold, which brought £2 19s. 6d. Nearly half of the silk worms died at Savannah, owing, as was then supposed, either to poisoned dew or warm weather.

December 4, 1742, General Oglethorpe sent five hundred trees to Ebenezer, with the promise of more if required. The indifference of the good Mr. Bolzius had by this time passed away, and he was now a zealous advocate for its extension. A machine was erected near his house, and two women succeeded very well, by which the people were stimulated to renewed exertions, and a public Filature was contemplated. The enterprise of these Germans, seemed to excite the envious disposition of Mrs. Camuse, with whom had been placed two women from Ebenezer; but the conduct of Mrs. C. in withholding information, rendered their acquirement inadequate, and Mr. Bolzius withdrew them from her charge. The first parcel of silk made, was sent to the Trustees, who expressed themselves pleased with its quality. In 1745, the weight of cocoons was two hundred and fifty-three pounds, and of spun silk sixteen and three quarters. In 1746, the weight of cocoons was three hundred and forty-four pounds, and of spun silk eighteen pounds. Early in this year a machine for winding, and coppers for baking, together with appropriate treatises on the art, were sent over by the Trustees, but the people were indifferent and apathetic.

The Germans, however, were as active as formerly, and Mr. Bolzius, in a letter to Von Munch, dated May 6, 1747, says, that "the people last winter planted more mulberry trees than for thirteen years before," for which he promised them a bounty of one shilling for every tree which yielded one hundred pounds of leaves. The silk balls raised at this place this year, were over four hundred pounds, three hundred and sixty-six pounds of which sold for £36 12s. 10½d. The amount raised in the whole colony, was eight hundred and forty-seven pounds of cocoons, and sixty two pounds of spun silk. In 1743, the Saltzburgers reared four hundred and sixty-four pounds, but their small trees were destroyed, and some of the larger ones injured, by the late frost. They this year succeeded admirably in spinning twenty-four pounds of raw silk, the want of a chimney and proper basins, which had impeded them before, in their rude building, having been remedied. The President, writing to Secretary Martyn, December 11, 1746, says: "The fundamental cause of its stagnation, is the unaccountable backwardness of some of our dames and damsels to employ themselves in attending to the worms during the time of feeding, which I have frequently taken notice of, and it cannot be imputed to the want of leaves."

During the same period only thirty-four pounds of spun silk were raised by the Trustees' agent in Savannah. Mr. Bolzius, under date of February 15th, 1749, thus writes: "The weather being now warm and pleasant, the mulberry trees have put forth their young leaves, and our people are now turning their minds towards making of silk," and then, after expressing his surprise that so few were disposed to this culture, adds:

"one reason for this reluctance, is ascribed to the circumstance that, by ordinary labor, about two shillings might be obtained per day, whereas scarcely a shilling could be earned in the same time by the silk concern." Seven hundred and sixty-two pounds of cocoons were raised, and fifty pounds thirteen ounces spun silk, and there were two machines erected in Mr. Bolzius's yard which drew off twenty-four ounces per day. On the 29th September, 1749, the Trustees promised £2 to every woman who shall make herself mistress of the art of winding in one year. And they also gave Rev. Mr. Bolzius permission to erect ten sheds, with clay furnaces, at an expense of not more than £2 each, and ten machines for reeling, at thirty shillings each, which he says could be made better than those at Savannah for £3; they also sent them ten basins, and the good Germans felt the impulse of this substantial encouragement. In 1750, though the people in other parts of the colony mostly relinquished the silk culture, the inhabitants of Ebenezer continued vigorously employed and interested in it.—On the 2d of June they received ten kettles from the Trustees, one of which, and a reeling machine, were given to each mistress in the art of spinning, and two of the best artisans received £5 for giving instruction to fourteen young women, to each of whom was bestowed £1, for attention and industry.

Over a thousand pounds of cocoons were raised at Ebenezer, and seventy-four pounds two ounces raw silk made, producing (the price being then thirty shillings) over £110 sterling. As illustrative of the luxuriant growth of the mulberry, it may be interesting to state that two trees in front of the parsonage, ten years old, measured three feet eight inches in circumference. In December of this year, eight more copper basins were received, and public confidence in the success of the undertaking seemed revived, notwithstanding Mr. Camuse and family had left the Province, and settled at Purysburgh in South Carolina.

On the 25th December, 1750, Mr. Pickering Robinson, who, together with Mr. James Habersham, had been appointed the preceding August a Commissioner to promote more effectually the culture of silk, arrived in Savannah.

Mr. Robinson had been sent to France, at the expense of the Trustees, to study the management of filatures and the necessary process for preparing the article for market, and thus, though no operative, was qualified to take the directorship of so important a branch of industry. His salary was £100 per annum, £25 for a clerk, and a tract of land was also granted him, which, in 1763, sold for £1500.

Mr. Robinson brought with him a quantity of silk worm seed, but all failed, save about half an ounce; the Commissioners determined at once to erect a filature, which should be a normal school to the whole province, and it was their opinion that it would be "a sufficient nursery to supply, in three or four years, as many reelers as will be wanted, when we make no doubt of many private filatures being erected, which can only make their culture a general staple." The dimensions were thirty-six feet by twenty, rough boarded, with a loft or upper story, for the spreading out of the green cocoons. It was commenced on the 4th of March, 1751. On the 1st of April, the basins were put up, and on the 8th of May the reeling began. To encourage the colonists, the Trustees proposed to purchase all the balls, and wind them at their own expense, and paid from 1s. 6d. to 2s. 4d. per pound for green cocoons. The Commissioners separated the cocoons into three sorts: 1st, perfect cones; 2d, the spungy and fuzzy; and 3d, the spotted, stained and dupions. This management, however, gave great offence to some of the residents in Savannah and Purysburgh, and Messrs. Robinson and Habersham requested the Vice-President and assistants to determine the respective prices and publicly announce the same, which they did on the 26th April, by a proclamation, wherein, by way of bounty, they promised to pay for cocoons delivered at their store in Savannah, the following sums, namely: for cocoons made by one worm, hard, weighty and good substance, 2s. per pound; for the weaker quality, pointed, spotted or bruised, 1s. 3d.; for dupions, (those made by two worms,) 6d.; for raw silk, from 1st quality cocoons, 14s. per pound; for that made from 2d quality, 12s.; the product of the double cones, 6s. per pound; and they also offered, if delivered at the filature, for best cocoons, 3s. 6d.; for middling, 1s. 8d.; and for inferior, 1s. 1d., a series of prices truly astonishing, when we reflect that the real merchantable worth of a pound of cocoons is scarcely ever 6d.

Experiments were made at the filature to ascertain the relative quantity of each of these qualities in a given weight of cocoons, and the results were, that in fifty pounds of green cocoons there were twenty seven pounds of the first sort, ten pounds four ounces of the second, and twelve pounds twelve ounces of the third. After curing or baking, these fifty pounds weighed only forty-six pounds five ounces, showing a loss in ponderosity of nearly eight per cent. Besides the arrangement above specified, the cocoons were still further divided for the purpose of reeling into white and yellow, and these again, subdivided into five each, namely: 1st, hard and weighty; 2d, little woolly and weaker; 3d, very woolly and soft; 4th, spotted and much bruised; 5th, double worms.

Mr. Camuse, son and daughter, who, it appears, gave the Commissioners no little trouble by their perverse conduct, returned to Savannah and were engaged to labor at the filature, at three shillings per day, at which Mr. Habersham exclaims, "monstrous wages!" The reelers now advanced with much proficiency, and five of them, on the 16th of May, wound off eleven pounds of cocoons each. The proportion of raw silk to the cocoons, appeared, on a variety of trials, to be nearly in this ratio:—

May 10,	1751,	55 lbs.	cocoons,	1st quality, produced	117⅞ oz.
" 11,	" 8	"	"	6-9 pr thread,	18½
" 13,	" 11	"	"	produced	21½
" 15,	" 55	"	2d	"	109
" 18,	" 20	"	"	"	24
" 22,	" 15	"	1st	"	20⅜
" "	" 10	"	2d	"	13½

The whole amount of cocoons raised in the province, was six thousand three hundred and one pounds, of which two thousand pounds came from Ebenezer, and four thousand pounds were made at Whitefield's Orphan House. Two hundred and sixty-nine pounds and one ounce of raw silk, and one hundred and sixty one pounds of filogee, were prepared, notwithstanding over three hundred and eighty pounds were lost by vermin, fire and mould. The expense of the culture was large this year, owing to the erection of the filature, &c., which swelled the sum to £608 9s. 8½d. sterling. The private journals of that day kept at Savannah and Ebenezer, acquaint us, in some measure, with the arduous nature of the Commissioners' labors, and the difficulties they encountered from the want of funds, the intractableness of laborers, the novelty of the attempt, the imperfections of machinery, and the bitter opposition of those who should have sustained and encouraged them. The public duties of Mr. Habersham prevented his constant attention to this business; but the whole time of Mr. Robinson was devoted to the filature, directing the sorters, aiding the novices, advising the reelers, and in every way exerting himself to obtain success. His engagement with the Trustees expired on the 30th of August, 1751, but finding that his intended departure depressed the friends of the culture, he was solicited by the local government to remain another year, and, generously sacrificing private to public interests, he complied with their request. Mr. Habersham thus speaks of Mr. Robinson: "I think him the most prudent as well as the most capable person I ever knew, to undertake such a work, and if he could be continued here, I doubt not but that he would turn out a number of well instructed reelers, who would be able to conduct filatures at Ebenezer, Augusta, and other parts of the province." So great was the confidence which the Trustees had in him, that he was appointed an assistant in the government at Savannah; an honor which he declined, and in the same letter stated: "If due encouragement be not given to the culture of raw silk, for the term of at least fourteen years, I positively cannot think of settling in America." These gentlemen recommended the building of a house, sixty feet by twenty-six, as a cocoonry, great loss having been experienced for the want of such a structure.

In 1752, Mr. Robinson returned to England, and his place was partially supplied by Joseph Ottolenghe, a native of Piedmont, and a proficient in his art, who came to Georgia on the 18th of July, 1751, and took charge of the filature in April, 1753. In a letter to Secretary Martyn, dated September 11, 1753, Mr. Ottolenghe says, that "there were fewer cocoons raised this year, as the worms mostly hatched before the trees leaved, and that, "the people were willing to continue the business." One hundred and ninety-seven pounds of raw silk were made this year, and three hundred and seventy-six pounds in 1754, besides twenty-four pounds of filosele. The people of Augusta became interested in this manufacture, and entered, with considerable spirit, into the undertaking, promising to send hands to Savannah, yearly, to learn the art of reeling: their enthusiasm, however, soon evaporated.

On the 29th of March, 1755, a certificate, signed by thirty-nine eminent silk throwsters and weavers, was given to the "Commissioners for Trade and Plantations," stating that after examining three hundred pounds of raw silk, imported from Georgia, "we do sincerely declare that the nature and texture is truly good, the color beautiful, the thread as even and as clear as the best Piedmont (called wire silk) of the size, and much clearer and even than the usual Italian silks;" and furthermore, "it could be worked with less waste than China silk, and has all the properties of good silk well adapted to the weaver's art in most branches."

In 1755, five thousand four hundred and eighty eight pounds of cocoons were raised, and four hundred and thirty-eight pounds of raw silk spun. The good effects of the filature were now happily evident in the increased interest of the planters in the subject, who sent both their daughters and young negroes to acquire the art of reeling. In 1756, three thousand seven hundred and eighty-three pounds and one ounce of cocoons were received at the filature, and two hundred and sixty-eight pounds of raw silk reeled.

The liberal policy of the Commissioners, who had no private ends to answer, caused them to recommend the establishment of additional filatures, and in their letter to the Trustees, June 12, 1751, they advise the erection of one at Ebenezer, and another contiguous to Savannah, but Mr. Ottolenghe opposed this course and arrogated to the one in Savannah the entire monopoly of the culture. Jealousy appears to have been very conspicuous in Mr. Ottolenghe's character, and his opposition to the Saltzburgers and depreciation of their efforts, arose from this suspicious trait. He aimed to render himself solely necessary, and aspersed everything which seemed to militate with his fancied superiority. This appears not only from letters of Governors Reynold and Ellis, but from his own correspondence, where this caution and fear of rivalry is plainly discernible. His course gave offence to the Ebenezer people, who had already erected a filature in their village; who had been at a great sacrifice to send their wives and daughters to learn the art of reeling in Savannah, and who had hoped to carry on the manufacture under their own supervision and for their own benefit. Mr Ottolenghe, however, overruled their views and required all cocoons to be delivered at Savannah, and to be reeled there. Each basin at the filature had two apprentices, besides others who were employed in sorting the balls, &c., and the various operations connected with the trade, employed nearly forty persons.

In 1757, over five thousand pounds of cocoons were received at Savannah, and three hundred and sixty pounds of raw silk spun, which, says Governor Ellis, would have been more, if the eggs had not failed; and in a letter, dated 11th of March, 1757, he says, "the raising of silk seems to be no longer a matter of curiosity, it employs many poor people, and is approaching towards a staple."

Seven thousand and forty pounds of cocoons were deposited in the filature in 1758, but while the friends of this business were rejoicing in the assured success of their experiment, they were saddened by the destruction of the filature, which took fire on the 4th of July, and was totally consumed. The wound silk, which had not yet been shipped, amounting to three hundred and fifty pounds, was saved, but several thousand weight of silk balls, together with much of the reeling apparatus, were destroyed. Another and more capacious building was immediately erected and was ready for use the ensuing season.

In 1759, ten thousand one hundred and thirty-six pounds of cocoons were raised in Georgia, four thousand pounds of which were from Ebenezer, and the proceeds of their culture alone, for the season, reached £700 sterling. The opinion of those engaged in the culture, as expressed to Dr. Jared Elliot was, "that it was more profitable than any other ordinary business."

The cocoons delivered at the filature in 1760,

weighed seven thousand nine hundred and eighty three pounds, and there were spun eight hundred and thirty-nine pounds. Mr. Ottolenghe was now honored with the full appointment of "Superintendent of the silk culture in Georgia," with a salary appropriate to his station.

Five thousand three hundred and seven pounds of cocoons, and three hundred and thirty-two pounds of raw silk were produced in 1761. Governor Wright, under date 13th of July, says: "The greatest appearance that ever they had here was destroyed in two nights' time, by excessive hard and unseasonable frosts, and there is likewise a degeneracy in the seed, as Mr. Ottolenghe tells me." These frosts occurred on the 5th and 6th of April. Parliament, this year, made a grant of £1000 towards defraying the expenditure for the silk culture, and it was annually renewed until about 1766. By means of this gratuity, Mr. Ottolenghe was enabled to give a high price to the rearers of cocoons, and thus sustain the encouragement so judiciously commenced.

In 1762, fifteen thousand one hundred and one pounds of cocoons were delivered at the filature, and one thousand and forty-eight pounds of raw silk reeled, which Mr. O. declared to be the finest and best silk ever produced in Georgia.

The year 1763 showed an increase of cocoons but a decrease of silk, there being fifteen thousand four hundred and eighty-six pounds of the former and only nine hundred and fifty-three pounds of the latter. The occasion of this disparity was a season of cold, rainy weather, towards the close of April, by which the later cocoons were injured, and rendered almost useless.

There were delivered at the filature, in 1764, fifteen thousand two hundred and twelve pounds of cocoons, notwithstanding the season was so unfavorable, that Gov. Wright mentions the case of one man who expected to make from five to seven hundred pounds, who only succeeded in raising one hundred pounds of cocoons. Eight thousand six hundred and ninety-five pounds were sent by the Saltzburgers, and the whole amount yielded eight hundred and ninety-eight pounds of raw silk.

In addition to the grant of Parliament, a society instituted in London, for the encouragement of arts, manufactures and commerce, offered certain premiums for the advantage of the British American dominions, among which were:

"For every pound of cocoons produced in the provinces of Georgia and South Carolina, in the year 1764, of a hardy, weighty and good substance, wherein only one worm has spun, 3d.; for every pound of cocoons produced in the same year, of a weaker, lighter, spotted or bruised quality, 2d.; for dupions, 1d." These premiums were to be paid under the direction of Mr. O., with proper vouchers that the same were raised in either of the provinces specified.

It was agitated in 1765, to reduce the price of cocoons from 3s. to 1s. 6d. per pound, a measure which produced much dissatisfaction, and as a consequence there was a considerable falling off in the amount of balls and silk, only twelve thousand five hundred and fourteen pounds of the former, and seven hundred and twelve pounds of the latter, together with seven hundred and twenty pounds of filosele being produced. To prevent the depression consequent on this reduction, Governor Wright suggested, that instead of so much per pound, as formerly, that the ten largest quantities should receive, the highest £50, the next greatest parcel £45, and so on, gradually decreasing with the decrease in weight, until you reached the lowest quantity, to which £10 would be awarded; thus, while the expense would be greatly lessened to the Trustees, the stimulus of reward would be sufficiently sustained. This advice was not adopted, though owing to the urgent remonstrances of those best acquainted with the business, the reduction in the bounty was only 9d. instead of 1s. 6d. On the 25th April, 1765, the following order was published in the "Georgia Gazette:"

"Notice is hereby given to all whom it may concern, that by direction of the Right Honorable the Lords Commissioners of Trade and Plantations, the price usually paid for cocoons is now reduced, and that no more than 2s. 3d. per pound will be paid for cocoons raised in this province, and delivered at the public filature this season.

"By order of His Excellency the Governor.

"Geo. Baillie, Commissary."

This bounty was still further reduced in 1766, when by order of the Board of Trade, only 1s 1d. was paid per pound. The dependence of this culture on the weather, was signally instanced this year, from the fact that though many who had hitherto raised cocoons, abandoned it at the reduction of the bounty, yet such a large crop had never been produced before; over twenty thousand three hundred and eighty pounds of cocoons being delivered at the filature, which, however, only produced one thousand eighty-nine pounds of raw silk, and eight hundred and fifty pounds of filosele. This amount of reeled silk was not at all proportionate to the weight of the cones, resulting, as Mr. Ottolenghe said in a letter to Governor Wright, October 2, 1766, "to the badness of the seed, and consequent inferiority of the worms." In 1760, the cocoons weighed only seven thousand nine hundred and eighty three pounds, and yet eight hundred and thirty-nine pounds of raw silk were spun; at which rate, the product this year should have been about two thousand pounds.

On the 26th of June, Henry Kennan made proposals to the Board of Trade, for carrying on the filature; but they were of a nature not at all advantageous to the culture, and Gov. Wright, in his reply, on the 21st of October, disapproved of the plan, and exposed the fallacy of his scheme, which was in consequence abandoned.

In 1767, ten thousand seven hundred and sixty-eight pounds of balls were raised, and six hundred and seventy-one pounds nine ounces of raw silk spun; the decrease of cocoons being caused, first, by withdrawing of the Purysburgh cocoons, which last year amounted to five thousand five hundred and fifty-one pounds; and second, by the reduction of bounty, so that while last year the cocoons were delivered in by two hundred and sixty-four different persons, only one hundred and sixty individuals were this year devoted to the culture. The silk, however, was of a better quality, and sustained its high reputation in the London market.

In 1768, another plan was proposed by Mr. Delamar, "in order the more effectually to establish the growth of raw silk in America." His proposal was, to pay a bounty of 20s. per pound on every pound of good, clear raw silk imported from any of His Majesty's dominions in America, to be paid on the price such silk might sell for at public sale in London; at the expiration of ten years, ten per cent. bounty was to be allowed; the ensuing five years at five per cent., after which time the bounty was to cease. This was the general feature of his plan; it was not, however, adopted, though in many respects its provisions were highly judicious and appropriate.

But this branch of industry and commerce was fast waning before the increasing culture of more sure and lucrative products, and only one hundred and thirty-seven different persons brought cocoons to the filature this year. Governor Wright in his official letter to the Earl of Hillsborough, July 1, 1768, says, "I am persuaded that few, or none but the very poorer sort of people, will continue to go upon that article.—Several substantial persons, who did mean to make it an object when the price was higher, have, to my knowledge, given it over. The reason, my Lord, is evident; for people who have their fortune to raise or make, will always turn themselves in such a way, and to the raising and making of such commodities, as they think will answer best; and it is very clear to me, that those who have negroes, may employ themselves and negroes to better advantage, &c., than by raising cocoons at 1s. 6d. per pound, although that is, as I have said, 7, 8 or 9d. more than they are intrinsically worth."

Cluny, in his "American Traveller," printed in London 1769, says, "The climate of Georgia has been found to agree, in every respect, with the silk worm." Experience, however, proved that the climate was not sufficiently equable to secure permanent and continued success. Governor Wright, in the letter quoted above, says, "the variable and uncertain weather in spring, makes it precarious," and facts amply confirm this statement. Only five hundred and forty-one pounds of raw silk were made this year, a smaller amount, with one exception, than had been produced for ten years. In 1769, the quantity was still more decreased, both from the reluctance of the people to raise worms, and the unfavorable weather in spring. Governor Wright, on the 20th of June, 1769, says, "We had a most extraordinary prospect, till the middle of April, when I thought every thing safe, yet we had very cold rains on the 17th and 18th, which were succeeded by hard black frost on the 19th and 20th, and destroyed a great part of the worms, and will reduce the silk very much."

The silk business was now on the irretrievable decline, though it still maintained a nominal existence, and received the encouragement of Parliament. The special bounty which had hitherto been paid on cocoons, over and above their merchantable value, was suspended, and by a statute of 9 Geo. III., c. 38, a premium of twenty-five per cent. from the 1st of January, 1770, to the 1st of January, 1777; of twenty per cent. from the 1st of January 1777, to the 1st of January, 1784; and of fifteen per cent. from the 1st of January 1784, to the 1st of January, 1791, on the ad valorem value of all silk produced in America and imported into Great Britain in vessels regularly navigated by law, was substituted in its place.

The inhabitants of Ebenezer resumed the culture, which with them had long been dormant, and its revival at that time was principally owing to the influence of a very worthy man and magistrate, Mr. Wertsch, who, sanguine himself of ultimate success, had imparted to the Germans a portion of his own enthusiasm.

In 1770, they shipped two hundred and ninety-one pounds of raw silk, the result of their own industry, and as the filature at Savannah was discontinued in 1771, the Earl of Hillsborough, ever anxious to advance the produce, warmly commended the zeal of the Saltzburgers, and directed President Habersham to distribute "the basins and reels that were left in the public filature, to such persons as Mr. Wertsch shall recommend to be proper objects of that bounty;" and in the same letter he promised that he would endeavor to procure for them, this year, "a small sum from Parliament, to be laid out in purchase of utensils for the assistance of the poor sort of people in your province." This promise he redeemed.

So popular had the silk business become at Ebenezer, that Mr. Habersham, in a letter dated the 30th of March, 1772, says, "some persons in almost every family there, understand its process from the beginning to the end." In 1771, the Germans sent four hundred and thirty-eight pounds of raw silk to England, and in 1772, four hundred and eighty-five pounds, all of their own raising. They made their own reels, which were so much esteemed that one was sent to England as a model, and another taken to the East Indies by Pickering Robinson. The operations at Savannah were now totally discontinued, though Mr. Ottolenghe still styled himself "Superintendent of the Silk Culture in Georgia," and in consideration of his long and faithful service in that office, received an annuity of £100.

In a message of Sir James Wright, to the Commons House of Assembly, 19th of January, 1774, he says, "The filature buildings seem to be going to decay and ruin; may it not, therefore, be expedient to consider what other service or use they may be put to?" And the Assembly answered: "We shall not fail to consider how it may be expedient to apply the filature to some public use;" and henceforth it was used as an assembly or ball-room, a place where societies held their meetings, and where divine service was occasionally conducted: more recently, it was converted into a dwelling house, and was thus appropriated at the time of its destruction by fire on the afternoon of March 25, 1839.

Thus ended the grand project for raising silk in the Province of Georgia; for though some few individuals, together with the people of Ebenezer, continued to raise small quantities, yet, as a branch of general culture, it has never been resuscitated. The last parcel brought to Savannah was in 1790, when over two hundred pounds were purchased for exportation, at from 8s. to 26s. per pound.

On reviewing the causes which led to the suspension of this business, after so many exertions and such vast expense, which, it must be remembered, the profits of the culture never reimbursed, we find, first, the unfriendliness of the climate, which, notwithstanding its boasted excellence, interfered materially with its success. Gov. Wright frequently speaks of its deleterious influence, and the fluctuations in the various seasons, evidenced, to demonstration, that the interior was better adapted to the agricultural part of the business, than the exposed and variable

sea-board. Mr. Habersham, in a letter to the Earl of Hillsborough, dated Savannah, 24th of April, 1772, thus expresses himself on this point: "Upwards of twenty years ago, if my memory does not fail me, Samuel Lloyd, Esq., of London, who was one of the late Trustees for establishing this Colony, and was fourteen years in Italy, and very largely concerned in the silk business, wrote to me, that the best silk was produced at a distance from the seacoast, owing, I suppose, to the richness of the soil, which made the mulberry leaf more glutinous, nutritive and healthy to the silk worm; also, to their not being obnoxious to musquetoes and sand flies, and probably, likewise, to the weather being more equal and less liable to sudden transition from heat to cold: and on a conversation this day with Mr. Barnard, of Augusta, he assures me, that from two years experience in raising cocoons there, he lost none from sickness which frequently destroys two-thirds of the worms here; and he further says, that Mr. Ottolenghe told him that the silk reeled from the Augusta cocoons, "made the strongest and most wiry thread of any raised in these parts."

Second, the expensiveness of living, and the dearness of labor, which was as high as 1s. 8d. to 2s. per day, whereas 2d. or 3d. was the usual price paid the peasant in silk-growing countries. Governor Wright, in a letter to the Earl of Hillsborough, frankly told him that, "till these provinces become more populous and labor cheaper, I apprehend silk will not be a commodity, or an article of any considerable amount.

Third, the great reduction of the bounty, which being the stimulus to exertion, ceased to operate as an incentive, when from 3s. 3d., it fell to 1s. 3d., and finally to a mere premium on the general quantity imported. The poor could not subsist on these prices, and the rich could employ their lands to much better advantage than in cultivating an article which would not repay the expenses of labor: and, lastly, the increasing attention bestowed on rice and cotton, sealed the fate of the silk culture, and the planters soon learned to consider the latter of no importance, in comparison with the large and lucrative crops yielded by those more staple commodities. Other reasons might be mentioned, but these sufficiently account for its decline there, and its total neglect even to the present day. During the morus multicaulis epidemic, which spread over our country in 1838, Savannah, it is true, did not escape, and for a time the fever raged with much violence, but the febrile action soon subsided, leaving no permanent benefit, and only a few fields of waving foliage, as a deciduous memento of this frenzied excitement.

That silk can be produced in Georgia equal to any in the world, does not admit of a doubt, but whether it will ever be resumed, and when, is among the unknown events of the future.

CULTIVATION OF INDIAN CORN.

From a paper read before the Dorchester (Md.) Farmers' Club. Published by order of the Club.

Requested under a resolution of the last Club meeting, I submit to them a few additional remarks, in support of the mode of the culture of Indian corn, indicated in my last paper, on that subject. [See April No. So. Cult. p. 52.]

It will be unnecessary for me, before the members of this club, to urge the point of the indispensable necessity of the presence of Nitrogen, for the perfection of all plants designed for animal sustenance—it is sufficient to demonstrate, that the sources of this essential, elementary material, are more economically appropriated under that culture, than by the usual practice of recent plowing, and *cross* plowing, &c. &c.

The two great sources of this useful element, are 1st, the direct product of all organic bodies, in a state of decomposition—united with hydrogen, in the form of ammonia; and with oxygen, as nitric acid—2d, the indirect supply from the atmosphere, at large, when it has been diffused, from bodies decaying on the surface of our lands.

From the infinite accumulation of these materials, it is unquestionable, that the atmosphere must be loaded with these gaseous products, as well as with all other vaporable substances—and it is equally so, that being soluble in water, they will of necessity mix and descend with the rain and snow, which may fall upon the earth from the regions in which they were floating.

Notwithstanding this obvious necessity, of the presence of these gases, and others, occasioned by the causes named, yet, being not apparent to the senses, farmers, indeed in *general*, will not acknowledge the fact; and many others do not appreciate their *quantity;* which, at the first falling of rain, or snow, and especially after their long suspension, is greater than would be imagined, without actual examination—as I assure you, I have frequently witnessed, on analysis, for *my own assurance* and *gratification*.

I have alluded to this important fact, in my former paper, and I renew it, with the more earnestness, because it forms the chief basis or principle of the mode of culture therein advocated; and if admitted, the conclusion is unavoidable, that, as before explained, it is better adapted to economise the atmospheric supply of vegetable nutriment, as well as to prevent the waste, by dissipation of the products of the decomposing sward, than the usual practice of recent and cross plowing.

The *soil*, too, will be improved, not only by the artificial *fixity*, given to these volatile substances—the gases—but by the salts and alkalies of the putrescent sward which is placed and preserved in a condition to promote fermentation.

In point of *fact*, results have accorded to theory a large share of corroboratory evidence.

Though motives may be misconstrued, I will venture in aid of the problem I have proposed for solution to adduce cases of results, in comparison with those of the usual methods - for which I refer to the publications of the facts—set forth in the Delaware Advertiser, Wilmington; and in the American Farmer, Baltimore.

The first named paper notices a sweep-stake, made up by several gentlemen in Delaware, who admitted me as a member—for the best crop of Indian corn, on one acre;—the Am. Farmer, perhaps more accessible, also published it, at the same time—1829, vol. 11, p. 314; my method then, differed from the present, only in the planting of *double*-drill and one plant left, in place of single drill and two left, which latter I have found to be preferable; I think, too, in one deep bar furrow, which I have discontinued.

The product of my acre was something more than one hundred bushels shelled corn—and I obtained the stake—a silver pitcher;—I understood that my competitors all *cross plowed*.

The files of the Am. Farmer, also, in 1827, vol. 9, page 257, contains a notice of my success, in a competition for two premiums offered by the Md. Agricultural Society—for the best products of Indian corn, on ten acres, and on five acres; both of which, I had the gratification to receive—in evidence of the preference of my mode of culture—which gave me ninety bushels per acre on the five acres—and seventy six per acre on the ten.

On the second—the Maryland case, there happened a considerable drouth—and my neighbors predicted destruction to my crop—but it suffered less than theirs, which was cross plowed; which is well attested by a sweep-stake silver pitcher inscribed to that effect—which I received from them; and several of you gentlemen happen to be of the number, that made the handsome contribution; and I hope, that we may long live to enjoy the festive libations of that, and similar trophies, which you have obtained, on similar occasions, for similar achievements, on that arena of competition where victory leads to the comfort and happiness of mankind

The inveteracy of custom and prejudice, may long continue the practice of recent, and cross plowing—but I beg of you generally, to make the experiment, fairly, on a small square of your fields, if you please; and I am fully convinced, you will find the results, which I have stated, and the reasons on which they were founded, most fully and satisfactorily sustained.

This inveteracy of custom and prejudice has done much to retard the onward march of agriculture; and while its influence continues, it is a vain hope, that we shall see in general practice, a system based on principles of science and unerring philosophic induction;—while this impediment continues, the charge of "*book-learning*" will be, as it now is, a popular theme of derision; a synonym of folly with the most of our farmers; while it continues, the fact of *printing* or *writing down* an established truth, will be, as it now is, enough to discredit it, with a large class of our countrymen at home and abroad, possessing in other respects, an ordinary sagacity; it is our *business*—it is our *purpose* to ameliorate this unfortunate condition of fatuity—and teach by *ocular process*—by *results*, which may be *viewed* in *comparison* that they have not attained that *ultimate principle* of skill, which they fancy they have, innately, derived from their forefathers, and that one higher step may yet be taken by them to advantage; if successful in the reclamation, we may claim a portion of public gratitude—if not, yet by the *effort*, we have performed our duty.

Joseph E. Muse.

From Ellsworth's Report for 1844.

OKRA.

Washington City, *January*, 15, 1845.

Dear Sir:—I take the liberty to call your attention to the cultivation of one of the most valuable of vegetables, destined, at no distant day, to expel from our markets one of the most extensive articles of imports, and now admitted free of duty. I mean *okra*, whose excellence in soup is universally known and acknowledged. *Its ripe seeds burned and used as coffee, cannot be distinguished therefrom;* and many persons of the most fastidious taste have not been able to distinguish it from the best "Java." It is very easily grown. The seeds may be sown in May, in drills 4 feet asunder, an inch deep and 8 inches apart, and cultivated like corn or peas. It sends up a strong stalk, and yields a great abundance of seeds, and the "coffee" made from it is very healthy. I think it matter of great importance, especially to the western States, and herewith send a bag of seeds for distribution. Very respectfully,

Hon. H. L. Ellsworth. J. F. Callan.

Extract from the Farmers' Encyclopædia.

Okra, (*hibiscus esculentus.*)—This plant is extensively cultivated in the West Indies, from whence it has been introduced into the United States. The pods are gathered green, and used in soups. They form an important ingredient in the celebrated gumbo soup of New Orleans, and other southern places. The pods are filled with seeds and a mucilage, of a bland and highly nutritious quality. Hence, the okra is frequently recommended to persons afflicted with dysentery and other bowel complaints, eaten either boiled or made into soup. When buttered and spiced, they afford a rich dish; and, with vinegar, they make a good pickle. The plant comes to maturity in the middle States, and the pods are abundant in the Philadelphia market. Those who become once accustomed to this wholesome vegetable, contract a great fondness for its peculiar flavor. In Lousiana, and other southern States, a dinner is scarcely considered complete without okra cooked in some way or other; and the poor consider it one of their greatest blessings. The pods are of a proper size when 2 or 3 inches long, but may be used as long as they remain tender. If fit for use, they will snap asunder at the ends; but if too old and woody, they must be rejected. One peck of the tender pods are to be cut crosswise into very thin slices, not exceeding one-eighth of an inch in thickness; to this quantity, add about one-third of a peck of tomatoes, previously peeled and cut into pieces. The proportion of tomatoes may be varied to suit the taste. A coarse piece of beef (a shin is generally made use of) is placed in a pot or digester, with about 2½ gallons of water, and a very small quantity of salt. This is permitted to boil a few minutes, when the scum is taken off, and the okra and tomatoes are thrown in. With these ingredients, in the proportions mentioned, the soup is very fine. Still, some think it improved by

addition of green corn, Lima beans, &c. The most essential thing to be attended to is the boiling, and the excellence of the soup depends almost entirely on this being done faithfully; for, if it be not boiled enough, however well the ingredients may have been selected and proportioned, the soup will be very inferior, and give but little idea of the delightful flavor it possesses when well done. A properly constructed digester is decidedly the best vessel for boiling this or any other soup in; but, where such a utensil is not at hand, an earthen pot should be preferred; but on no account make use of an iron one, as it would turn the whole soup perfectly black, instead of the proper color, viz: green, colored with the rich yellow of tomatoes. The time usually required for boiling okra soup is about five hours; during which, it should be occasionally stirred, and the ingredients mashed. When taken off, the original quantity will be reduced to about one-half, and the meat "done to rags;" the whole forming a homogeneous mass, of the consistence of thick porridge.

THE HESSIAN FLY.

[Observations communicated at the raquest of the Hon. H. L. Ellsworth, by E. C. Herrick, librarian of Yale College, Conn.]

The insect commonly called the *Hessian fly*, which has for so many years ravaged the wheat-fields of our country, appears to have been wholly unknown here before the American revolution. It is usually stated that the insect was first noticed in the year 1776 or 1779, on Staten Island and the westerly end of Long Island, and was generally supposed to have been introduced among straw brought hither by the Hessian troops in the service of Great Britain. The ravages of the insect soon attracted general attention; and as early as the year 1788, serious apprehensions were excited in England that the destroyer might be conveyed thither in some cargo of wheat. The alarm there was so great, that the government took up the matter; "the privy council sat day after day, anxiously debating what measures should be adopted to ward off the danger of a calamity more to be dreaded, as they well knew, than the plague or pestilence; expresses were sent off in all directions to the officers of the customs at the outports respecting the examination of cargoes; despatches written to the ambassadors in France, Austria, Prussia, and America, to gain that information, of the want of which they were now so sensible; and so important was the business deemed, that the minutes of the council, and the documents collated from, fill upwards of 200 octavo pages." (Kirby and Spence, i, 50.) On the 25th of June of that year, an order in council was issued, prohibiting the entrance into Great Britain of wheat raised in any of the territories of the United States; intending, by this measure, to keep out the much dreaded enemy. Soon after the arrival of the news of this order, the supreme executive council of Pennsylvania addressed a letter of inquiry to the "Philadelphia Society for promoting Agriculture," who promptly replied that the plant of the wheat alone was injured, and that the insect was not propagated by sowing the grain which grew on fields infected with it. The prohibition was doubtless based on the erroneous representation of Sir Joseph Banks and Dr. Blagden, which they continued to enforce even after they were better instructed by Dr. Currie. It is sufficiently remarkable, that, although the wheat was prohibited an "entry," it was allowed to be stored; so that the Hessian fly, if concealed among the grain, would, after all, have had a good opportunity to escape into the country. In eight or ten months, the government bought the imprisoned wheat at prime cost, kiln-dried it, and resold it at great loss, and almost immediately took off the prohibition. (Memoir of Currie, ii, 65.)

In the course of a few years after this, the Hessian fly was found in every part of our country where wheat was cultivated. From the period of the revolution down to the present time, no insect in the land has received so much public attention, or has called out so many scores of pages of observation and speculation. These are to be found scattered through magagines, agricultural journals, and common newspapers. But, in defiance of them all, the Hessian fly continues its destructive work, and is probably as little under the actual control of man as it was half a century ago.

Whether this insect was an original inhabitant of this country, or was imported by the Hessian soldiers, is a question not yet settled. At the time of the discussion which led to the prohibitory order, an extensive inquiry in Europe resulted in the conclusion that the insect was wholly unknown there. Yet, in the year 1834, it was found existing in several parts in southern Europe, and injuring the wheat in the same manner as in this country. This important discovery was made by my friend, Mr. James D. Dana, who had previously been engaged with me in the examination of the Hessian fly, and was well qualified to decide upon the case. (American Journal of Sciences, xli, 153.) Moreover, we have an account from the vicinity of Geneva, in Switzerland, reported by Duhamel, of an insect destroying the wheat there as long since as 1732, in the manner of the Hessian fly; and an account, in 1823, by Raddi, of what is probably the same insect, in various places in Italy. No traces have been detected of any insect of the habits of the Hessian fly, in our country, earlier than the year 1776; and if this insect is a native of North America, what plant sustained it before wheat, rye and barley were imported? On the other hand, we have no proof that the Hessian fly has ever been found in Germany; and it is certain that, if the wheat were reaped in the ordinary manner, nearly all the available insects would be left in the stubble; and, further, the straw alleged to have been brought by the Hessians must have been that which ripened in the summer of 1775, and from which most of the insects which it contained would have escaped before August, 1776. On a question of such uncertainty, no one need quarrel with another's opinion.

The first scientific description of the Hessian fly was published in the Journal of the Academy of Natural Sciences of Philadelphia, for July, 1817, (No. 3, i, 45,) by the late distinguished entomologist, Thomas Say. He there gives it the systematic name of the *cecidomyia destructor;* and to his description adds a few remarks relative to its habits, and furnishes, also, an account of another insect, by which the fly is often destroyed. Without going into a minute and tedious technical description, the following account is offered as probably sufficient to enable an observer to identify the insect in its various transformations: The Hessian fly is a two-winged insect, with head, eyes, and thorax black; the head is small and depressed; the palpi (or mouth feelers) are three or four jointed—the basal one being the smallest; the antennæ are about half as long as the body, and consist each of from 14 to 17 oval joints, besides the basal joint, which appears double; the wings are large, hairy, rounded at the tip, and have each two or three longitudinal nervures; the abdomen is of a tawny red, and furnished, irregularly, with many black hairs; consists of seven rings or segments, besides the ovipositor, which is of two sides, and of a rose-red color; the ovipositor, when extended to the utmost, is about one-third as long as the abdomen; length of body, from the front of the head to the end of the abdomen, about one-eighth of an inch; the legs are long and slender, pale red, and covered sparsely with dark hair. The male is equal in size to the female, but generally less black, with antennæ somewhat longer, and about three-fourths the length of the body. The joints of the antennæ are globular, and slightly separated from each other. Several other species of the genus *cecidomyia*, or one closely allied to it, are common in this region. But the Hessian fly is the largest and darkest of our species with which I am acquainted.

The eggs are laid in the long creases or furrows of the upper surface of the leaves, (*i. e.* the blade or strap-shaped part) of the young wheat plant. While depositing her eggs, the insect stands with her head towards the point or extremity of the leaf, and at various distances between the point and where the leaf joins and surrounds the stalk. The number found on a single leaf varies from a single egg up to thirty, or even more. The egg is about a fiftieth of an inch long, cylindrical, rounded at the ends, glossy and translucent, of a pale red color, becoming, in a few hours, irregularly spotted with deeper red. Between its exclusion and its hatching, these red spots are continually changing in number, size, and position; and sometimes nearly all disappear. A little while before hatching, two lateral rows of opaque white spots, about ten in number, can be seen in each egg. In four days, more or less, according to the weather, the egg is hatched; the little wrinkled maggot, or larva, creeps out of the delicate membranous egg skin, crawls down the leaf, enters the sheath and proceeds along the stalk, usually as far as the next joint below. Here it fastens, lengthwise and head downwards, to the tender stalk, and lives upon the sap. It does not gnaw the stalk, nor does it enter the central cavity thereof; but, as the larva increases in size, it gradually becomes imbedded in the substance of the stalk. After taking its station, the larva moves no more, gradually loses its reddish color and wrinkled appearance, becomes plump and torpid, is at first semi-translucent, and then more clouded with internal white spots; and, when near maturity, the middle of the intestinal parts is of a greenish color. In five or six weeks (varying with the season) the larva begins to turn brown, and soon becomes of a bright chesnut color. In this state, the insect bears some resemblance to a flax-seed; and many observers speak of this as the *flax-seed* state. The larva has now become a chrysalis, or pupa, and takes no more food. The pupa within gradually cleaves off from the outer skin, and, in the course of two or three weeks, is entirely detached from it, so that the skin of the larva (now brown and hardened, and of a sort of leathery texture) has become a case or shell for the pupa inside. The *pupa shell* is, of course, in size and form, like the larva: it is oval, bulging out beneath, and of the same curve above as the outside of the stalk; divided by cross lines into twelve segments, and is about an eighth of an inch long. Within this shell the pupa gradually advances towards the winged state; it contracts in length, but not in breadth; and its skin appears covered with minute elevations. Just before evolution, we find the pupa invested in a delicate membrane, or scarf, (which, not long previous, was its outer skin,) through which many parts of the future fly may be distinctly seen. Finally, this scarf splits along the thorax, or back, and the insect comes forth, both from this and the pupa shell, a perfect two-winged fly.

This is, in brief, the history of an individual which has been so fortunate as to escape all the numerous enemies with which its race is surrounded from the moment the egg is deposited; but of these, more hereafter.

In the northern and middle States, at least, winter wheat is sown in September or October. Soon after the plants have appeared above ground, the Hessian fly begins to lay her eggs upon them; and this operation is continued during several weeks, according to the season. The eggs laid on the green leaves are in a few days hatched, and the young larvæ crawl down the stalk, and take their stations; generally clustering around the stalk at the nearest joint below. Here, by sucking of the plant, they increase in size, become full and hard, and, pressing deeply into the stalk, they impair its growth; and if their number about one joint is large, the stalk is killed. Frequently the plant, although impoverished, advances far enough to head out; but when the grain begins to fill, its own weight, or perhaps the wind, causes the stalk to break down. The injury done to the wheat is occasioned by the exhaustion of the sap, and by the pressure on the yielding stalk.

In five or six weeks, the larvæ stop feeding, the outer skin turns brown, and within this brown and leathery case the pupæ pass the winter—generally a little below the surface of the earth. In April and May, the fly is again found depositing her eggs on the same wheat, (viz: that from grain sown the preceding autumn,) and also on the spring wheat which has just come up. These eggs hatch, and the larvæ therefrom operate in the same manner as those of the autumn previous. These larvæ become pupæ about the middle of June. The flies which lay their eggs in the spring are probably in part from the pupæ which became such late in the preceding autumn, and partly from pupæ contained in stubble left the preceding summer. The period of the existence of the Hessian fly in the pupa or flax-seed state is exceedingly variable. After much observation, my own opinion is, that, in general, pupæ which become such late in the autumn evolve the winged insect partly during the next spring, and partly in the summer and autumn following. Those pupæ which become such about June, evolve the winged insect partly during the next autumn, and partly during the year succeeding.

The Hessian fly is attacked by numerous foes, which, in various stages of its existence, destroy a large part of every generation. Whether it has, in its winged state, any enemies, except the ordinary destroyers of flies, I know not. The eggs, while lying on the leaves of the young plant, are visited by a very minute four-winged insect, (a species of platygaster,) which lays in them its own eggs. From later observation, it appears that, occasionally, as many as five or six eggs of this parasite are laid in a single egg of the Hessian fly. The latter egg hatches and becomes a pupa, as usual; but from the pupa case, instead of the Hessian fly, issues one or more of these minute parasites.

The pupæ, while imbedded in the stalk, are attacked by at least *three* different minute parasites, (four-winged hymenopæra,) which, boring through the sheath of the stalk, deposite their eggs in the body within; and the latter is finally devoured by the parasite larvæ. These are the principal means by which the multiplication of the Hessian fly is restrained within tolerable limits.

Although the loss annually sustained by the wheat-growers of this country, in consequence of the ravages of the Hessian fly, is severe, yet it is well nigh impossible to ascertain even its probable amount. As long since as 1800, Dr. S. L. Mitchell, of New York, affirmed that the "insect is more formidable to us than would be an army of twenty thousand Hessians." In 1804, President Dwight, of Yale college, remarked that "this insect is feeble and helpless in the extreme, defenceless against the least enemy, and crushed by the most delicate touch; yet, for many years, it has taxed this country, annually, more, perhaps, than a million of dollars." At the present day, the amount of the injury inflicted probably far exceeds what it was forty years since; and to discover some feasible mode of exterminating the insect, or at least of arresting its ravages, is an object of great importance to this country.

Various remedial measures have, from time to time, been proposed; most of which I will here state.

1st. Steeping the seed-wheat in elder juice, solution of nitre, boiling water, or other liquids; or rolling in lime, ashes, or some other substance, in order to kill the eggs. But as the eggs of the Hessian fly are not on the seed, they will never be hurt by such processes. So far as these means give vigor to the plant, they may be of some little service.

2d. Sowing seed obtained from places in which the insect has not made its appearance, (American Museum, iv, 47.) This recommendation also assumes the error, that the eggs are laid on the grain, and will be found, as it has often proved, useless as respects this insect.

3d. Abstaining rigidly throughout the whole grain-growing region of North America from planting wheat, rye, barley, or oats, for one, two or three years, and thus starve out the insect! This plan might be effectual, but would obviously involve some inconveniences.

4th. Manuring the land very highly, so that the plants will grow vigorously, and be sooner out of the way of the insect, and also better able to resist it. This proposal has some merit, but does nothing towards destroying the insect.

5th. Sowing some variety of bearded wheat, flint wheat, &c., supposed to have a harder and more solid stalk than common wheat, and better able to withstand the impression of the larvæ. A suggestion of some value, but, equally with 4th, leaves the insect unharmed.

6th. Fumigating the wheat-field, and sprinkling the young wheat with infusion of elder and with other steeps. If successful; which is quite uncertain, it is plain that these measures are impracticable on a large scale.

7th. Sowing winter wheat very late in the autumn, so that the fly shall have mostly disappeared before the plants are large enough to be attacked. No doubt this plan is to some extent useful, but the wheat sown late is in great danger of perishing during the winter. The fly will of course attack it in the spring, yet one attack will do less damage than two.

8th. Sowing oats early in autumn on the intended wheat-field. It is supposed the fly will lay its eggs on the plant; then let them be plowed in, and the wheat sown. The fly having nearly exhausted itself on the oats, the wheat will suffer less. This plan may possibly be of some partial utility.

9th. Drawing a heavy roller over the young wheat both in autumn and spring. This process must be useful in crushing many eggs and larvæ.

10th. Permitting sheep and other animals to graze the wheat-fields while the insects are laying their eggs. By these means, large numbers of the eggs will be devoured with the leaves.

11th. Burning the stubble immediately after harvest, and plowing in the remains. This is by far the most practicable and effectual mode of exterminating the insect, or, at least, of checking its increase. In the stubble are many pupæ of the fly, at this time completely in our power; if, in reaping, the stubble is left high, the fire would sweep rapidly over a field, and destroy nearly all these pupæ; the few which escaped the fire, would, by the plow, be buried so deep as to perish in the earth; mere plowing in of the stubble must be highly useful. If the two recommendations last named were thoroughly put in practice over the whole country—not only upon wheat, but also on rye and barley, and any other plants attacked by the Hessian fly—the ravages of this insect would, in all probability, ere long, become scarcely worthy of notice.

It may not be improper, in this place, to state that the foregoing account of the habits of the Hessian fly is derived from my own long-continued observations, and that I have moreover endeavored to consult all the papers of any importance which have been published on the subject.

There are in the United States, besides the Hessian fly, several other insects which attack the wheat while in the field. Those persons who assert that the former lays its eggs on the grain in the spike or head, have undoubtedly mistaken for the Hessian fly some one of these other insects. The following brief notices of the more important of these enemies, I have abridged from the accounts comprised in Dr. T. W. Harris's "*Treatise on some of the insects of New England, which are injurious to vegetation;*" (Camb. 1842: 459 pages, 8vo.,) a work of great interest and value.

In it the inquirer will find a faithful digest of all the reliable information we have on the numerous insects which injure our plants, fruits, and trees; and, in addition, he will learn the means of defence, so far as any have been discovered. The book ought to be in the hands of every intelligent farmer and orchardist.

1. A grain moth (Angoumois moth—*alucita cerealella*, Oliv.) probably the same as described by Col. Carter, in the *Transactions of the American Philosophical Society*, volume i, 1771; and by J. Lorain, in Mease's *Archives of Useful Knowledge*, volume ii, 1812. It is about three-eighths of an inch long when its wings are shut. The upper wings are of a light brown satin color and lustre, covering the body horizontally above, but drooping a little at the sides. The lower wings and the rest of the body are ash-colored. The moth lays her eggs usually on the young and tender grain in the field; each caterpillar from these eggs selects a single grain, burrows into it, and remains concealed, devouring the meal within. Subjecting the grain to a heat of 167° Fahr., for twelve hours, in an oven, will kill the insect.

2. *The English wheat fly* (*tipula tritici*, Kirby,) is a small orange-colored two-winged gnat, which lays its eggs in the head of wheat while blossoming. The maggots from these eggs are without feet, tapering towards the head, at first perfectly transparent and colorless, but soon becoming orange-yellow; and when mature, are each about an eighth of an inch long. It is supposed they devour the pollen, and prevent the setting of the grain; the maggots fall from the spike to the earth, within which they undergo their final transformations. This insect (or one very similar to it) has done much damage in the northern States and in Canada for several years past; but no effectual mode of preventing the mischief, or of destroying the insect, appears to have been devised.

3. *The wheat caterpillar.*—This is a span-worm of brownish color, with twelve feet—six near each end of the body. It feeds on the kernel in the milky state, and also devours the germinating end of the ripened grain. It is said to be found in the chaff when the grain is threshed. We have little certain knowledge concerning the parent insect or its transformations.

In addition to these three, there are probably other insects more or less injurious to our wheat crops. Much has been published in our journals relative to these depredators; yet their habits are imperfectly understood, and many of the accounts are confused and contradictory. It is greatly to be desired that all who have the opportunity should endeavor to make careful observations, and communicate them to the public.

These observations must be accompanied by accurate descriptions of the insect under examination, and in its various stages; otherwise, most of the labor will be spent in vain.

GRADED HILL-SIDE DITCHES.

From the Farmers' Register.

In the February number of the Register, p. 88, I find an article headed "Scraps of Farmers' Conversation, by the Editor." The conversation of Mr. Old I propose to notice. He is opposed to the system of graded hill-side ditches as a preventive to the washing of the land in heavy falls of rain, because they will not effect the object desired—that on a hill-side having several ditches, if the one near the top should break, the quantity of water thereby increased in the next, together with the force with which it would descend, the second would break, and, for the same reason, all the rest; consequently more injury would be done to the land than if they had not been made. He gives an instance of one of his ditches, that he had been so particular with as to attend to in person, having been broken by the lodgment of a few blades of fodder, which seems to be conclusive that the system was a bad one. If Mr. Old had given the grade and depth of his ditches, we should have been better able to form an opinion whether he had given the plan a fair trial or not; but we are left in the dark in these particulars, as well as to the distance between them and the manner his rows were laid off; whether in checks up and down the hill, or drills parallel with the ditches, or horizontally. For the last ten years I have practised the system of graded hill-side ditches, accompanied with the horizontal cultivation, as I believe with great success in preventing my land from washing. I must, therefore, ask leave to differ with Mr. Old. If our

fields were perfect inclined planes, it would be a very easy matter to so run our rows as for each to bear off its own water so gently as not materially to wash the land. This, however, being far from the case, the question is, the best protection under the circumstances of the many undulations that we find in even a small field. It is the practice of many farmers in this section of Georgia to put in the necessary number of ditches and lay off their rows parallel with those ditches and cultivate the crop in drills. The argument for this practice is, that the rows, having the same grade of the ditches, will mainly bear off their own water. They forget that the natural undulations will very soon vary the grade, in fact change the direction of the water in different points of the row; it is therefore embodied and presses its way down the hill to the ditch below, drives across that and materially injures the land. The reason for the imperfection of this system is obvious. In one part of the field the hill may be very abrupt, at another less so, and at another still less. A ditch passing across all these various declinations, ascending the hollow on one side and descending it on the other to the natural eye, but by the instrument keeping the same grade. Now it is very easy to perceive, that in a parallel of thirty feet from the ditch, you would lose your grade, for the reason, that the fall, supposing the parallel on the lower side of the ditch, would be much greater where the hill was very abrupt, than where it was less than half as much so. Therefore the parallel row would be many inches out of the grade of the ditch at the steep part of the hill, and as compared with the ditch where the land was less abrupt. Hence the water would be thrown into bodies by this method of operation, to say nothing of the many smaller undulations, almost imperceptible to the eye, producing the same effect. And when once sufficiently embodied, the volume continues to increase, and it soon defies obstruction.

It cannot be difficult for any one who has ever used a level to comprehend the force of this reasoning It has been observed, that if fields were perfect inclined planes, it would be a very easy matter to have each row pass off its own water. Now the horizontal rows form an inclined plane taking the rows together. True the direction of the plane is changed as often as the direction of the level changes, nevertheless the same grade is preserved, measuring from the top of one bed to the top of the other; therefore the direction of the plane is changed as often as you have undulations in the land. Your level being perfect, of course your inclined plane is perfect, and when you have such a fall of water as to overrun your water-furrows, it is as apt to break over on a ridge as in a valley; for the rows being level, the water remains where it fell—the inclined plane being perfect, the water passes over in a kind of sheet, until received by the ditch below, and by it borne off. To keep your level perfect, short rows will occur between you guide furrows; because where the land is most abrupt, the guide furrows will be nearer together than when it is less so, by running rows about parallel with the guide rows the place for the short rows will be indicated by the filling of the space where the land is most abrupt; the remaining space will then be to fill with short rows by the judgment of the operator.

But to the ditches. A field that is intended to be ditched should be sown in small grain, in order to have as smooth a surface to operate on as possible. The ditches should be from 75 to 150 yards apart, regulated in their distance apart by the fall of the land, and the ability of the soil to absorb water. In fields laying comparatively well, in many cases three or four ditches are sufficient for a field of fifty acres, of which the operator must be the judge. The grade may be regulated by the ability of the soil to absorb water, giving greater fall on clay lands, and less on sandy porous soils. For land having average ability to absorb water, my grade is *three inches to twelve feet*, increased or diminished a quarter of an inch, as the soil is more or less capable to absorb water. The instrument used is the common rafter level, having a stride of twelve feet, with a plumb bob suspended from the crown by a very small cord, so boxed as to prevent the influence of the wind. The grade is indicated by a mark on the cross-bar, say two and a half feet from the crown. The grade that you may wish may be ascertained by first finding a perfect level. This is best done by reversing the ends of the instrument, until the plumb-line will stand at the same point on the cross-bar. Then place under one end of the level a block just the thickness that you wish your grade, and the plumb-line will indicate the declination on the cross-bar. I usually commence operations near the highest point of the land and in the middle of the intended ditch, and let that point divide the water, having it to run each way. By this method I encounter a less volume of water at any one point. The ditch being marked out by a chop with a hoe at each step of the level, it is opened by running several furrows with a plow, and the dirt drawn out on the lower side with weeding hoes. I prefer the ditches wide rather than deep, and concave in the bottom. A plow may pass them without inconvenience, and they occupy about the space of one corn-row. The necessary number being laid out and opened, you may proceed to lay out your guide furrows, by the mark that indicates the true level. The space between the guide furrows will be filled by running parallel rows alternate to the guide rows, the width that you may desire, for either corn or cotton, until the space is filled, finishing with short rows where they may be required, as before directed. The land is then thrown into beds by the rows, the beds opened, and the crop planted. In the cultivation, if the level is well preserved in the rows, and the water-furrows kept well open, all the water will be retained in common rains; but if the rain should be so great that the land cannot absorb it, nor the water furrows hold it, it passes over the bed in a sheet—because of the inclined plane formed by the horizontal rows—and is received by the ditch and borne off. If the grade of the ditch is a proper one, and well preserved the whole length, and properly opened and well attended to the first year, when a turf will be formed on its bank, I will ensure it not to break by the lodgment of a few blades of fodder.

The reason that hill-side ditches are in disrepute with many is because the grade is not a proper one, or not well preserved. In one part of the ditch, the grade being too great, the water passes too rapidly; in another, not being great enough, it passes too sluggishly: consequently there must be an accumulation at the point where the water moves slowest, and the volume continues to increase until the ditch is overflowed, for which the system is condemned, when the true cause is in the operator. I have seen many fields injured from improper ditching, but it has not proved to me that the system is a bad one. If Mr. Old will give us a statement of his method of operation, and cogent reasoning why the system of graded hill-side ditches is a bad one, and point out one that is better, and sustain it by incontrovertible proofs, for myself I will most cheerfully abandon the one and embrace the other.

Of one thing I am certain, that my land washes less than my neighbors' who have not resorted to the means that I have to prevent it; and I believe that many of them are finding it out, from the fact that they have commenced the system of graded ditches.

Since writing the above, I have had on my farm a very hard and washing rain, when the land was not guarded against it. Soon after the rain a field was examined that came into my possession last winter, and in the spring the necessary number of ditches had been made in it, and no attention given them since. By the way, it is a very broken field, and many gullies had been formed, across which the ditches passed as a matter of course. The crop is corn, and cultivated horizontally. I found the field well preserved. Even in the gullies across which the ditches passed, the loose dirt which fell from the plows in crossing them had not been washed out. I confidently expect, by filling these gullies with pine bushes, which I shall do this fall previous to sowing wheat, to have these gullies entirely filled, and corn growing on them.

My object in noticing the conversation of Mr. Old is to elicit information on the subject of preserving hilly land from washing from the heavy falls of rain, frequent in this country during the crop season, and as the gentleman condemns the system that I have practised with success, as I believe, I felt called on to vindicate it, and at the same time ask him for a better and more effectual one. R. S. Hardwick.

Jocassie, Hancock co., June 28th, 1842.

The Camellia.—Of this magnificent exotic there are several species and upwards of fifty varieties. The species known as *C. Japonica and Seticulata*, with their varieties, are in general cultivation in the Green Houses of Europe and America. Some of the varieties of the *Japonica*, as for example, *C. J. Variagata*, the variegated red, are so hardy as to stand the open air, either as standards, or planted against a wall; particularly if their roots are protected during frosty weather. It may here be stated as an important fact, that many tender and half hardy plants will grow freely, and produce abundance of flowers, if their roots and collars are protected, in a temperature that would kill them immediately, if these tender parts were exposed to the influence of the cold. Camellias are commonly cultivated in sandy loam, and this soil is perhaps the best for them when they are grown in pots; but when planted out in the open ground, they will thrive exceedingly well in sandy loam, mixed with rotten dung, or leaf-mould. When the plants are in a growing state, they require abundance of water, both the roots and over the leaves; taking care, however, never to wet the leaves when the sun is shining upon them; as whenever this occurs, the leaves become stained, or blotched, and look as though they were scalded. During the growing season, the Camellia requires a temperature of from fifty to sixty degrees, but when the flower-buds are formed it may be lower, till the beginning of winter, when the buds begin to swell. At this season, the temperature ought not to be suffered to fall below fifty degrees, otherwise the buds will be liable to drop off; and they will also drop if watering be neglected. It must be observed, that all the varieties of the *Camellia Japonica* cannot bear too much heat, and they prefer the shade to broad sunshine. Of the different species, *C. Sasangua*, and its beautiful variety, *C. S. Maliflora*, are the most tender. *C. Seticulata* is distinguished by the large size and brilliant colour of its flowers. It was, at first, thought tender, but it is now found to be quite as hardy as the Japonica.

Propagation.—All the species and varieties may be propagated by cuttings, taken off at the base of a leaf, or at a joint, as soon as the wood is ripened, and planted in sand under a glass; but the finer varieties are generally propagated by layering, and inarching or grafting. The French Nurserymen have a very rapid mode of procuring plants by grafting, which they effect under bell-glasses, in strong moist heat, with scions of the young wood, on stocks formed of cuttings struck the same season. The above is taken chiefly from the Ladies' Companion of the Flower Garden.

Cow Pea.—There is no doubt, in the minds of many practical farmers, that the cow pea is the best renovator of worn out, or tired land, that can be used in the South. Plant early in May, between hills of corn, and cultivate with corn; the produce for hogs alone will doubly pay all cost; it will in reality almost equal the corn crop. The vine and foliage will not only shade the land, but protect from the washing, and afford a fine quantity of vegetable matter to turn under. The reports furnished by experienced farmers, in various parts of our country, particularly in southern countries, prove this beyond a doubt. The pea is the clover of the South.—*Plow Boy.*

The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 6.....JUNE, 1845.

To our Exchanges.—Many of the papers with which we exchange are still directed to us at Augusta, instead of Athens. Will those who have not already done so, attend to this, and oblige by directing to us at Athens, Ga., in future?

The Hessian Fly.

The article in this paper, prepared for Mr. Ellsworth's report, by Mr. Herrick, of Yale College, we cannot commend too highly. Mr. H. is a gentleman distinguished for his habits of close and accurate investigation, and has devoted a great deal of time and labor to the study of the origin, progress and modes of existence of this most destructive insect. It is to be hoped that the suggestion of Mr. Herrick, as to the best mode of exterminating it, will be universally adopted.

The Mind and the Soil of the South.

The earnestness with which the minds of Southern men are beginning to be engaged in the improvement of the soil of the South, certainly furnishes an occasion of very high gratification to every one who takes an interest in the welfare of the country. The proofs of this direction of the public mind are abundant, and are too strong to admit of mistake. We find them, in Virginia, in the establishment of a State Agricultural Society, with Edmund Ruffin as President, and a Vice-President for every congressional district in the State; and especially in the very liberal support given by the public to the Southern Planter, published at Richmond by C. T. Botts. In North Carolina they are seen in the circulation of agricultural papers and books among the people, and in the establishment of an agricultural school under the care of Bishop Ives. In South Carolina we find them in the support given to two agricultural papers, and the establishment of a State Agricultural Society, with subordinate Societies in most of the districts of the State; and in the very liberal provision made by the State for paying the expenses of agricultural and geological surveys. They are found in Alabama, in the establishment of a State Agricultural Society; and in Georgia, in the establishment of a State Society, with the Governor of the State at its head; in the increase of County Societies, in which our distinguished men are taking the lead, as Governor McDonald in Cobb county, and Judge Berrien in Chatham; and in the increase of the circulation of agricultural papers among the people in all parts of the State. And in this connection we cannot forbear to mention that the Chatham County Society has ordered twenty-five copies of the Southern Cultivator for the use of its members; and that the Hon. Robert Toombs has ordered fifty copies for gratuitous distribution among his constituents.

Feeding Plants.—Hill-Side Ditches.

Many persons there are, still living, who remember that one of the great inducements people had to break up their establishments in the settled parts of the country, and move to "the purchase," as the different acquisitions of territory from the Indians, in Georgia and Alabama were called, was the excellent pasture for cattle afforded by the forests. The great abundance and luxuriance of the wild grapes, and wild pea-vine, and cane, every where, in "the purchase," enabled the domestic animals of the first settlers to live and thrive with very little care from their owners. Many persons seemed to think that this state of things would last always. It seemed never to have occurred to them that as the purchase was filled up with settlers, and the forests with their cattle, these native pastures, rich and luxuriant as they certainly were, would be exhausted. It has so turned out, however; and now, no man having any pretensions to thrift thinks of his cattle being able to provide for themselves, as they did formerly. They have to be fed from the products of the soil obtained by the labor and care of their owners.

Precisely the same thing has happened with our crops. Plants are living bodies, and require food, as well as animals. When the country was first cleared up, plants found in the soil an abundance of their appropriate food, which had been accumulating there for ages. This was the golden age for planters. Corn, cotton, wheat, rye, oats—indeed every thing committed to the soil grew wonderfully, and produced most abundantly, requiring not much more care than did the cattle of those days ranging in the woods. Manure was not thought of, except as a nuisance to be gotten rid of. But from continual cultivation the food for plants, originally existing in the soil, has become exhausted, just as the food for cattle in the woods has become exhausted by continual grazing. New lands were cleared and treated in the same way, until there is very little more land to clear. And now, having consumed what nature had furnished, we are compelled to provide food for our plants with the same care and assiduity that is necessary in providing food for our cattle.

The kind of food to be provided for animals—that which suits them best—is easily ascertained. Offer food that is improper, and it is rejected at once. Plants likewise have the power of choosing to some extent; but we cannot see the exercise of this faculty, as in the other case. No one would think of feeding his hogs with hay, or his horse with pork. But it is not so easy a matter to ascertain what kind of food best suits different plants. Let a practical planter set about finding out, and it will take a year to make an experiment; on wheat, for instance: and even after the experiment shall have been made, he will, most likely, be as much in the dark as before it was begun. If he put an abundance of stable manure on his land, he may find his wheat prosper wonderfully, perhaps, during winter and spring; but when earing time comes, disappointment may come with it. The wheat that promised so well, may either run up to straw, and have few grains in the head, or the straw, from weakness, may not be able to sustain the head, or the whole field may be stricken with the rust. Now the planter may suspect that his wheat has been fed with improper food. But how is he to ascertain that? By making another experiment, and using another kind of manure. This will require another year, and, perhaps, result as the other did, in disappointment. To avoid all this trouble and vexation, he must call in the aid of science.—That kind of knowledge, which has been so contemptuously called book knowledge, is the only thing that can remove the difficulty. Science tells us what wheat is made of—grain as well as straw—that nature, to make one perfect wheat plant, uses no less than fourteen distinct elementary substances; and farther, that unless the plant can find certain ingredients of grain and straw in the soil, we must supply them to the soil before we can expect our wheat crop to prosper. Whether they are already in the soil must likewise be determined by science; and what kind of manure contains them in a state and quantity most suitable for the digestive organs of wheat, can be determined in no other way so well as by calling on science for the information.

To this point—providing food for plants—a very large portion of The Cultivator has been devoted, because it is an essential one. All real improvement must begin with it. The manner of applying this food properly, after it has been provided, is the next important point. On this, as on the other, our paper has contained a great deal of very useful information. But there is still a third—the best way to prevent the unnecessary waste of this food when it shall be applied—about which we have not yet published much, except as to one branch of it, and that is subsoil plowing. Enough has been said to arouse the public mind to the importance of that operation. But how prevent its waste, in this hot climate, by the influence of sunshine and rain, and also from our plants gorging themselves with it? Mr. Ruffin has divulged that secret, in his "Essay on Calcareous Manures." Where the soil is sandy, clay must be added; and sand to a soil too stiff from clay. But the great remedy is lime. This must be an ingredient in all good soils. It gives consistency to sand and makes clay friable. But the all important agency exercised by it, according to Mr. Ruffin's theory, consists in this:—that it fixes manure in the soil; just as, in dying, the mordant fixes the color in cloth; thus restraining the influence of the sun and rain in dissipating it, and so modifying and restraining the action of plants as to prevent them from gorging themselves with food, and bringing on a diseased action of their organs.

After all our labor to provide food for our

crops, and care to apply it properly to their nourishment, and assiduity to prevent the waste of it, in this region of heavy summer showers of rain, we are liable to have the result of our labors swept away in an hour. How prevent this catastrophe? Subsoil plowing is an important preventive, as it increases the absorbent powers of the earth wonderfully, and thus prevents, in all ordinary showers, every thing like the washing away of the soil from our hill-sides. But to guard against disaster from the extraordinary showers that often fall, subsoiling alone won't do. It would, in most cases, only serve to make the ruin more complete. Hill-side ditches judiciously arranged, and these alone, after subsoiling, will effectually protect us. These, wherever they have been tried, and have been properly constructed, have afforded perfect security. That they would do so was confidently asserted by theory; that theory was right in this instance, has been proved by practice. Mr. John Cunningham, of Greene county, will tell you so, if you ask him. Men have come from great distances to see his system of ditching. Mr. Hardwick, of Hancock, gives his experience on the subject, in an article in another part of this paper, which we cannot commend too strongly to the reader's attention. Mr. Affleck, of Mississippi, gives the weight of his name in favor of hill-side ditches, in an incidental remark in his article on Bermuda grass, in this number of the CULTIVATOR. And the committee that recently examined and reported on the condition of the farm of the Hon. J. C. Calhoun say, they "were both gratified and instructed by the extraordinary management of Mr. Calhoun, by which, through the instrumentality of guard drains on all his upland fields, placed at such distances apart, and graded in such strict conformity to hydrostatic principles, that his upland fields, even those of the greatest declivity, have sustained almost as little injury from the heaviest falls of rains, as the rich low lands at their base." We might add the testimony of many others to the same effect. Let this suffice for the present.

A Suggestion.

In connection with the fairs of our Agricultural Societies, we beg leave to make a suggestion which occurs to us as having a good deal of importance. At most of these fairs, premiums to a considerable amount, in silver cups or cash, are awarded. The object of these associations is to advance the interest, and elevate the character of those who are engaged in the great business of making bread, meat and clothing, out of earth, air and water; and one of the means of accomplishing this end is the distribution of premiums to those who shall excel in this business. Now would not this object be more surely accomplished by investing the funds intended for premiums in agricultural books, and distributing them instead of the money? The Planters' Club of Hancock County, will, at their fair in November next, distribute premiums to the amount of two hundred and fifty-six dollars. This sum, if invested in books on agriculture, would throw into that community an amount of information that would be very important, and the influence of which would be felt for generations to come. Two hundred and fifty six volumes of our best agricultural papers might, with this money, be put into the hands of the planters of that county.

We would particularly object to the use of silver cups as premiums, because they are not made by our own mechanics; and the money used to purchase them, therefore, has to go North, thus adding to the drain upon our resources and industry that has brought the South to what it is. If books will not suit, better by far give the money that the cups would cost, until we can have cups made at home.

The Agricultural Press.

The American Farmer, the oldest agricultural paper in the United States, heretofore published in quarto, weekly, at Baltimore, at $2 50 per annum, after the close of the present volume, is to be published monthly, in a large octavo form, each number to contain 32 double column pages, and be embellished with engravings—the price is to be reduced to one dollar a year.

Mr. Skinner, the father of agricultural literature in the United States, having been turned out of the office of Assistant Post Master General, for opinion's sake, has been engaged by Greeley & McElrath, to edit for them a monthly journal of agriculture. It is to consist of two parts: First, *The Farmers' Library;* and second, *The Monthly Journal of Agriculture.*—Each part will contain about 50 pages every month, and the price of the whole will be five dollars per annum.

English Laborers.

In the fifth letter of D. S. Mitchell to the editor of the Albany Cultivator, speaking of laborers in England, he says: "In the barn, two laborers were threshing wheat upon a slate floor, with flails similar to those in use with us. Before I left, the threshers suspended labor for dinner; and what was it? Half a barley loaf, and a bit of cheese!—this eaten squat upon the straw, and moistened with a jug of water, and cut in pieces with their pocket clasp knives.—This is no joke; it was their *dinner;* and yet a stone's throw away, lay the three hundred acre park for old oaks to fatten on, and herds of deer to dance over, and scores of hares to trip about, and breed, and die upon. Let our farmers and farm laborers thank Heaven that they are not set down within the range of such odious contrasts. And yet, and it is a shame to every man in America, who has a spot of land and a soul—these same laborers, dining on barley bread, will save enough of time and means, to put out the sweet brier at their cottage window, to train the ivy up their chimney side, and to keep the grass green and velvety at their door."

ERRORS.—In the last number of the CULTIVATOR there were three errors that require correction.

1. In the last two lines of the article on "The Agricultural Press," "extend the like amount of patronage *on* the Southern Cultivator," for *on* read *to*. 2. In the two last lines of the article preceding the extract from Mr. Gregg's Essay, page 72, in the words, "who ought to be scourged *from* folly," for *from*, read *for our*. 3. In the list of premiums of the Bowling Green Agricultural Society's Fair, the President's name is printed MOADY. It should be MOODY.

Broom Corn--Bones--Whip Handles, &c.

The Ohio Cultivator gives us an account of three brothers, named Eaton, who have engaged in the production of broom corn, and the manufacture of brooms, on a scale that will astonish many persons whose attention has been directed to the production of cotton exclusively. One of the brothers resides near Columbus, Ohio, and is, this year, engaged in planting between five and six hundred acres of the rich land of the Scioto Valley in broom corn. Another brother resides at Circleville, twenty-five miles farther down the Scioto Valley, and is planting four or five hundred acres—making together about one thousand acres!! Besides this they have numerous contracts with small farmers in the surrounding country for as much as they can raise. All is, when gathered and properly prepared, sent over the Atlantic to London, where the third brother resides, and carries on a very extensive manufactory of brooms. The demand for these brooms in England, is said to be unlimited: and the prospect is that these three brothers, by their enterprise, energy and industry, will soon make handsome fortunes—larger, perhaps, than will soon be made by planting cotton and selling at present prices.

We add hereunto an article from a Cincinnati paper, for the purpose of giving our readers an idea of some of the thousand and one ways there are in this world of making, not only a living, but a fortune too, besides planting cotton, or broom corn, or even packing and shipping sausage skins; and of showing how other people thrive by turning to account such things as we throw away as worthless.

From the Cincinnati Chronicle.

BONES—WHIP-HANDLES—IVORY BLACK—HOOFS—PRUSSIAN BLUE—OFFAL, &c.—This is a motley heading, but is exactly adapted to what we have to say. A few days since we took a ramble up Deer Creek. We were not walking for pleasure, although the atmosphere that encompassed us was *fragrant* with ——— that we will tell by and by. We hope that the word will not be driven from the English vocabulary by this too free use of it. The creek shore, above Ninth-street, is measurably lined, and in one instance, we believe, covered by slaughter-houses—some devoted to disposing of hogs, and others of cattle—tanneries, bone-mill, grease-trying establishments, and similar odoriferous vocations; and in the winter season the stream should be known as Bloody run, for such it literally is, its color being nearly scarlet. A brewery adds its mite, as well as a steam lard and tallow manufactory, to the general aggregate of which the creek is the depository.

But however undesirable is the brink of this murmuring stream, the vale through which it runs is nevertheless a fountain of wealth. Among the establishments there is one which is a common receiver of nearly all the offal of the city slaughter-houses. From it is turned out an immense amount of grease and inferior lard. A large proportion of the daily market beef-legs and shanks are purchased by the proprietor, and after the marrow and grease are extracted, the bones are sold for the various purposes of button-making, whip-handle finishing, the manufacture of China-ware, or porcelain, and also ivory black. Of the latter, large quantities are used in the manufacture of shoe-blacking; and a mill in this noted vale is expressly appropriated to the grinding of bone, pith of horns, &c., for the manufacture of black.

Of the small bone used for black and porcelain, this house ships to foreign ports, mostly

Europe, about 400,000 lbs. per year; and of the large bone, which are principally used for the ferrules and butts of whip stocks, and the manufacture of buttons, about 130,000 pieces.—These quantities are exclusive of the amount consumed here, which is very considerable, particularly of the former kind. A few years ago, nothing of the kind was done here, and, as far as bone was concerned, was entirely a waste. The prices here, are, for the small, $16 per ton. A large contract closes with 1844, for export to Europe, at that rate, packages included; and for the latter, $10 per 1000 pieces. The price last year was $8.

Soap grease is the great staple of this Vesuvius, very large quantities of which are shipped to the Eastern cities. Forty thousand dollars worth was mentioned to us as the value of what is at this time on sale in New York alone. The prices here now are, four cents for No. 1, and three and a half for No. 2.

One of the other articles made to a great extent, is neats'foot oil, from the nether legs and hoof. This sells at wholesale at sixty-two to seventy-five cents per gallon.

Another is sausage skins, with which not only our own market is supplied, but shipments are constantly making to the South and East.—They sell here at $10 per keg—size, the same as common lard kegs.

Hogs' bristles are another thing prepared by this and other houses, or house in the city, and of this article large shipments are also made, both of the combed and tied, used by saddlers, shoemakers, &c., and of the curled. The former kind sells at 20 to 25 cents per lb. The curled are used for the same purposes to which curled hair is applied—mattrasses, cushioned chairs, sofas, &c. Who ever thought of reposing on a pig's back?

One other thing we learned in this, our evening ramble, was, that we have with us a manufactory of Prussian Blue. The stock from which it is made is cattle's hoofs, and plucks, and the blood of hogs and cattle. The hoofs command $16 per ton. The manufacturer is a German. It is but a year or eighteen months since he commenced operations, and cannot be said to be fairly under way, but has sufficiently tested the experiment clearly to demonstrate the practicability of successfully competing with the foreign article, both as to quality and price, and he expects in a few years to be able to consume a very large proportion of the blood to be obtained here.

We were also told of an instance of a foreign demand for blood. The facts we have stated are a few instances of the economy with which science is capable of making us acquainted, and of the value of the skill by which it can be effected. Shall we cultivate the arts and sciences, and encourage skill and enterprise in our country?

The Protective System.

Though we have been frequently admonished by our friends not to meddle with any thing connected, in the remotest degree, with politics; and though we stand pledged to the public to abstain from such meddling, yet we must for once disregard the admonitions, and violate our pledge. The temptation is so great, we can't withstand it. The following article suits the state of things in the South so admirably, that we must republish it, let the consequences be what they may—trusting, however, that our readers will overlook this deviation from our prescribed course, in consideration of the pleasure they will have to find that even in Indiana, a State settled chiefly by Yankees, things are managed, in some respects, pretty much as they are in our own blessed land of sunshine and wastefulness.

A PLEA FOR THE PROTECTIVE POLICY.

Mr Hatch—Now that the heat of politics is somewhat subsiding, will you allow me to exhibit some of the disastrous results which I have witnessed in Indiana, by reason of the almost universal prejudice against a *protective policy.* I am very sure that there are some chapters in the subject of protection which our farmers have not had presented to them. In consequence of the loose notions prevalent on this subject, almost all the farms of Indiana are destitute of barns, stables, sheep-cotes, pig-pens, and hen houses. There are to be sure *things* very humorously and ironically *called* stables. Several times during the past summer, sudden showers have driven me into these stables.—They are very artfully constructed; for while they seemed designed to protect from the rain and wind, they in fact are made to answer the purposes of both. The shingles or clapboards are so arranged as to bring the rain in streams through into the enclosure; and the sides are adjusted so as to produce an admirable *draft* for the wind. I do not know how a horse could be *showered* and *chilled* more effectually than in the Hoosier stables. But the great part of all the herds and flocks are left without any protection, through our trying winters, except such as their instincts can devise.

To begin with the least: Turkeys and hens are left to roost upon trees, bushes, fences, well-curbs (and as looking down into the well might make them dizzy, they very properly turn their head the other way, which, besides being safer, ensures the concealment of their manure, otherwise offensive to the eye.) The reasons for anti-protection in this case are, doubtless:—1. The necessity of hardening the constitutions of fowls; 2. To give roosters finer astronomical observations, that their *crowing time* may correspond to the true sidereal time; 3. But chiefly as an act of reciprocity to coons, foxes and weasels, who are known to sympathize very heartily in the popular doctrines of *Free Trade.*

The condition in which sheep are left through the winter, shows that our farmers have calculated that *wool* needs no protection.

My sympathies are every year enlisted in behalf of cows and cattle upon our farms, and in our villages. No one can walk the streets of Indianapolis, without meeting the supplicatory glances of most forlorn cows at every nook, where they may hide from the piercing west and northern winds. Many of them are left to subsist by picking at the dry grass, seared by the frosts, or by ranging the woods for weeds, and even tender shoots of trees. I have seen outline cows craunching straw from crockery-crates, and litter from the stables, with a ravenous appetite. Perhaps their owners think that a cow can make milk with straw as easily as the Hebrews did brick. But these operations are very different, I think, though I have not tried either.

When I ventured one day meekly to expostulate with a crusty anti-protectionist on the subject, he sharply told me to "go to grass with myself," and I could only reply, "that his cow needed that mission more than I did." Around our cabins, and about farm houses of more pretension, may be seen a bevy of shivering creatures—crumpled with cold, or drenched with chilling rains, or coated with sleet.

In a still moonlight night, when a sound may be heard for miles—when the cracking foot-steps of a benighted traveller would echo through a whole village, how often have I heard the melodious murmuring of some dozens of swine, which have crept into a heap in the open air, to keep themselves warm. Their views of the ruinous effect of the anti-protective policy, are uttered at first in *staccato* grunts—these now and then swell out to a longer cadence and quite a number in chorus. And as some little pig insinuates himself under some veteran, there commences such a performance by the whole company, with varieties of tone, movement, and part, as I am bold to say, Mozart never dreamed of with all his music.

Whatever may be the effect of these notions against domestic *protection*, I am entirely certain that they work ruin to the great department of *Internal Improvement.* I beseech of you to exert your editorial authority to persuade our farmers to redeem some of their waste time from politics and sprees, and devote it to the purposes of domestic protection. B.

Original Communications.

Plantation Economy.

Mr. Camak:—It is really with some hesitation and misgivings that I venture to give you some of my ideas about farming in Georgia. There is so much agricultural bombast (misnamed scientific Agriculture) afloat, and the public taste appearing to receive that kind of thing so freely, that I fear any effort of mine to stop that conduct, and get farmers to try my mode of thinking and acting, would be, not only unsuccessful, but probably unpleasant; still, it would please me to be useful to the cause of agriculture, as I expect to devote the remainder of my life to that vocation; and it is with me a business of love as well as profit.

In farming, as well as in every thing else, every thing is simple when it is well understood; and the fault is, not that we know too little, but that we know too much. In a way, we have a little smattering of every thing, from Liebig down; and are so exceedingly deficient in the simple elements and practical manipulations, that we are incapable of practically and economically applying and using one useful idea.

At the present prices of produce, I see no prospect of prices ever being very high again; the principal profits of a farm must be derived from its *economy;*—I mean in the application of labor, as well as in the use of its product: and no man can justly be called an economist, who does not attend to small matters as well as small accounts. I go farther. I insist that no man can comprehend his business well, nor construct those better rules for its management, who is not intimately acquainted with the details; who does not understand well the elements of those ideas that he is attempting to systematize. Well, if this be true, what a deplorable condition of things we have around us! How many of our agricultural teachers know any thing of the first elements, or the manipulations of the business they are lecturing on? They can tell you all about ammonia, talk to you of oxygen, carbonic acid, sub-soil plows, hill-side ditches, how to make manure in your stock lots, and spread it on your lands; and probably they *may* know something of *diastase* and its function in a germinating seed. All these are useful ideas. I like to see them in their proper *place,* and introduced to the people in a practical way. But when they give us their *modus operandi,* it is too expensive. We can't dive too deep into nature's laws, provided we succeed in getting truth; but we can very foolishly and ruinously misapply—miseconomise a good idea.

One of the great secrets in the success of farming, is to be able to select and use cheaply the peculiar resources that each man finds about his particular location. Here is economy again, and requires an intimate knowledge of facts as well as discrimination. In fact, we may go through any farm that I know of, and I believe that 20 per cent. can be gained by a more judicious or economical application of the resources and efforts used, and pertaining to the farm. If this is true, would we not do well to commence our agricultural studies in the alphabet; and not commence reading until after we have past *cru-ci-fix.*

Man has been defined to be a tool-making animal. I believe when he goes into the field to work, he always takes some tools with him. Well, would it not be better for him to always select the most suitable ones, and then learn how to use them to the best advantage? How much of the success of a farm depends on the plows used, and how few persons have devoted attention to the structure and improvement of plows! On that subject I am sure great improvements can be made, and profitable economy used, both

in the application of horse-power, and the outlay for plows. The same remark is applicable to many other tools, though I have not space to enumerate them.

In reclaiming and fertilising our exhausted lands, much more can be effected by economy. Almost every farm and field has, contiguous to it, the elements of fertility that can be more cheaply used than the tedious process of hauling, to and from your farm-yard, litter and manure. For this you must study in the field rather than the books. The practice of deep or sub-soil plowing must be a powerful agent in fertilising, and improving the susceptibility of our exhausted lands. We had better study to understand this thing before we begin, else we will waste much labor as well as money, before we acquire the necessary tact:

I see, on every farm, much labor expended in hauling manure. Would we not do well to calculate the difference in the expense and results of raising and turning under green crops, litter, or whatever we have near the field? I think much economy could be used there.

On the subject of draining thoroughly all wet land, and ditching the hill-sides, so as to prevent washing, I believe all are now agreed; and I know, from experience, that much can be saved by understanding well the text, before you begin the commentary.

I could extend this paper, by giving more cases of bad economy in farming, though this will suffice for an illustration. I am not opposed to cautious speculation in farming, but it should be used to illuminate, enlighten; not to supersede, or supplant well-tried practices. Farming is, essentially, a practical business; and none but a practical, successful farmer should ever be high authority. Theory should be the handmaid, not the head of farming institutions; and though we can, by careful incredulity, improve our practices, by listening to the teachings of theory, there are few nuisances that we should be more guarded against, if we aim to thrive by farming.

I will return, and urge again on my farming brethren to first study and improve, as much as they well can, on those ideas, practices and tools that they expect to continue using on their farms. First make yourself master of that; then resort to the most successful practices and best experience you have around you, or that you have inherited from practical parents. Carry these home; modify and apply them to your peculiar wants. Make yourself familiar with the use of these; and then, when you have leisure, and you can appropriate two hours every day, sit down and hold a friendly confab, with those who do all their plowing in the shade. They will teach you how to spend money, and how to do a great many foolish things on your farm. But if you will listen carefully, and select with caution, you may, once in a while, get a good idea from them; and one good idea, properly used on a farm, will pay for any *ten* agricultural papers in the United States. But before you spend money on a new idea, study it well, if you want to profit by farming.

I may, at some future time, if I have health and leisure, give you my ideas more in detail, on particular practices and projects, that I see proposed to farmers, if I should be vain enough to suppose I could be useful.

Respectfully, J. S. WHITTEN.

Mount Zion, May 6, 1845.

For the Southern Cultivator.

Cotton Culture.

MR. CAMAK:—Having seen the report of Mr. R. P. Sasnett and others who have been experimenting upon Dr. Cloud's plan of planting cotton, and having, in '44, made a small trial myself, and discovering that my result approached so near in quantity that of Mr. R. P. Sasnett, I am encouraged to report through your very useful periodical, the quanty of seed cotton which I grew per acre. The land, in a natural state, is a sandy ridge, had been cultivated several years, and was, consequently, somewhat exhausted; perhaps six or eight hundred pounds might have been grown upon it, unassisted by manure. In '43 it was not cultivated, but was used as a pasture for calves. In February of last year, I had the land broken deep with a scooter plow, after which I hauled out my manure and laid it in piles at suitable distances. On the 2d of April, I laid off the rows at the distance of 2½ feet the narrow way. This was performed with a very narrow plow. On the 3d of April, the rows were run off the wide way, 4 feet, with a shovel plow, and the manure deposited in the check, in such quantity as to nearly fill the shovel furrow at each hill; after which the bedding or ridging was performed the wide way with a very simple kind of turn plow, leaving enough of the middles unplowed to retain the small scooter marks as guides in planting. On the 4th of April the ridges were opened with a small scooter and light stock, the seed rubbed in leached ashes, and a few dropped in each hill and covered with feet. The ground being dry at this period, the seed did not vegetate till after the fall of a shower, which was 15th April.—After the rain the middles were turned out. As soon as the cotton was up it was hoed, leaving three or four stalks in a hill. The second working was performed by running a small plow round the cotton, and leaving the middles unplowed, and hoeing out, leaving two stalks in each hill. In June the middles were plowed and the cotton hoed. At this period I discovered that the cotton was not inclined to branch properly, and consequently I thinned it down to one stalk in a hill.

At this time the plants were blooming, and on many stalks several bolls were found. Early in July I plowed and hoed the ground very lightly, which finished the culture. On the 16th July I topped the cotton plants; it branched so as to fill up the row the wide way, and produced two thousand and thirty-four pounds per acre. Had the thinning been performed in proper time, I doubt not but that the product would have been larger. This fact is detailed as an error in the cultivation. One stalk in a hill is enough, and if thinned as soon as possible every body knows that fruit will be produced the sooner.

The manure used was "compost," prepared from stables. The kind of seed planted was Rio Janeiro. I shall say something of this cotton in my next. Yours,

MILES SCARBOROUGH.

Mt. Pleasant, Meriwether co., April, 1845.

For the Southern Cultivator.

MR. CAMAK:—We have, this day, held the spring meeting of the Barbour County Agricultural Society, the proceedings of which we will send you as soon as they are published.—The number of reports presented by the farmers to the Society, showing the quantity of land planted in cotton, and the quantity in provision crops, compared with 1844, will show that, although we are planting largely of cotton, still the provision crop is much increased, with a considerable decrease of the cotton crop. We trust that our Society has become firmly established in the affections of the farmers of the country, and that the good effects of our association will be seen and felt throughout this region of country, in the improvement of its agriculture.

We are rapidly passing into the year 1845, and in a few more months the fate of the crop will be known. Up to the present time the prospects in this section of country cannot be said to be flattering, owing to the considerable quantity of cold weather and frosts in the month of March, and the long continued drouth in the month of April, and even up to the 10th of May, making near six weeks without rain: and when it is recollected that our sandy land soon swallows up the rain that falls, and becomes dry, the length of time that we have been without rain has been most seriously felt in checking the young crop in its growth, both corn and cotton. The oat crop, which is the principal small grain of this section, has been greatly injured for want of rain. Should the seasons be good from this time, the crop of the present year may be equal to that of last year.

As the subject of manures is every day becoming more and more important, I would be much pleased to see, in the CULTIVATOR, well written essays on the proper and best plan of preparing manure. I noticed last summer, in the county of Elbert, large quantities of oak leaves collected in the woods and thrown in piles, there to remain until spring, then to be applied to the land. I have commenced the making of manure by hauling the pine leaves (as my land is situated in the long-leaf pine country) into a lot where my cattle are penned. I haul into the same lot the blue marl. My cattle are constantly penned on the straw and marl. From the effect, up to the present time, the most salutary results will grow out of this system of manuring, as the cotton in the rows where we put the compost, is now twice as large as that where there was no manure put.

I would also be much pleased if some of the contributors to the CULTIVATOR would give, through its columns, the properties of the Bermuda grass, as to its value for stock. I am disposed to give up my hilly lands to the Bermuda grass as a pasture, and only cultivate the level lands, and manure them highly. By this arrangement I think I can grow wool profitably in this climate. I see that Mr. Affleck, of Mississippi, is out in favor of the Bermuda grass, and there is no man whose opinion I more respect than I do that of Mr. Affleck.

The olive seed that you had the kindness to give e are not as yet up. Still I hope they will come up, as I am anxious to make a trial to raise the olive.

We expect, if spared, to spend the summer in the West and North. As we expect to make our trip, as far as we can, an agricultural one, should any thing take place, or should I see any thing that I think will interest my brother farmers, I will write you. Your friend,

ALEXANDER MCDONALD.

Eufaula, Barbour Co., Ala., May, 1845.

For the Southern Cultivator.

Bermuda Grass.

MR. CAMAK:—I find in your April No. a call upon Mr. Spalding and myself for information on the subject of eradicating Bermuda grass. From my own experience I can give you but little information. I have made much inquiry, however, of others; and the result is, together with what little experience I have had, that it is an extremely difficult matter to *eradicate it entirely*; but not at all to smother and check it, so far as to permit the cultivation of any crop. Nor do I think it advisable to destroy it entirely; as, if a proper system of rotation be carried on, Bermuda should occupy the ground three years in seven—thus: 1, 2 and 3 years, Bermuda, cutting a crop of oats the first year; 4th, Egyptian or winter oats, (sowed the previous October, turning the Bermuda sod carefully and completely under—which, by the way, requires one of Ruggles, Nourse & Mason's sod plows) the oats followed by a complete covering of peas; 5th, Corn, with peas and pumpkins; 6th, Cotton; 7th, Cotton, with oats sowed amongst the cotton at the last tending—the treading will injure them but little—and after the oats are cut, the ground is left to be occupied by Bermuda for three years again—which will not be the case, if the previous crops have been well managed, without replanting. Apply the manure to the corn crop, and as a top-dressing to the Bermuda in March of the second year. *Of course*, the stock, with the exception of hogs and the sheep fattening for the butchers, have no business in the pea or corn field. The poorer spots, after receiving a dressing of manure, will be more rapidly improved and give a better return by two successive crops of sweet potatoes, covering the vines up carefully each time, than by any other crop.

Such a system will not only improve the land highly, each term, but it will allow of Bermuda grass being freely introduced. It would also directly enrich the planter, inasmuch as it would enable him to turn his attention to other things

than cotton; compel him to raise less of that overdone crop; enable him to gather it much sooner and send it to market in better order, as he would assuredly gather much more to the acre; and it would, with the addition of *a complete series of horizontal ditches*, entirely stop his land from washing.

It is always remarked here, that no matter how poor the ground may be that is taken possession of by Bermuda, it rapidly improves, becoming dark-colored and mellow, and showing in the bettered appearance of the corn, the improvement that the soil receives from a covering of this grass.

I have never recommended the introduction of this grass, without adding a caution as to the trouble it is certain to occasion under improper management. At the same time there is one query I should like answered—is it not better to cover with this grass the naked, exhausted, washed hills that have been thrown out as incapable of being longer cultivated in corn and cotton with advantage, and which exist to the extent of many thousands of acres in all the cotton growing States, *even if it never could be eradicated*, than to leave them as they now are, utterly worthless and valueless? Few of the lands in this State or in Georgia, are so worn, but that a covering of Bermuda grass could be had upon them, capable of supporting five head of sheep to the acre, and every year's grazing would improve them. Had I such a farm as many I could name, I would infinitely rather *cover it with Bitter Coco*, than leave them as they now are.

Even now there are many farmers in Kentucky, Ohio and Indiana, who dread the introduction of Blue grass on their farms, so troublesome is it under careless or improper management. I do not consider Bermuda grass much more so.

In the rotation recommended above, I have a special eye to the smothering of this grass.—With the oats sowed amongst the cotton, I should sow, and *do sow*, about a gallon of red clover seed per acre, which affords a fine bite after the oats are cut, and until the Bermuda covers the ground. True, red clover lasts but one year here—in the North it lasts two—ripening its seed and dying. But, if not grazed too close, there is enough of seed dropped to cover the ground pretty well a second year. And whether or no, it far more than pays, in early and rich pasturage, the trouble and expense incurred.

There are not near enough of winter oats grown in the South. They make a famous winter pasture, and are *much* better feed for horses and mules than corn, costing, at the same time, much less labor to make, and leaving the ground unoccupied by the middle of May, for a full crop of that most valuable of all our crops, *cow peas*.

Volumes might be written upon the advantages to the cotton planter of changing his present miserable practice of occupying two-thirds instead of two-sevenths of his land in cotton, and of giving the attention they deserve to oats, cow peas, sweet potatoes, Bermuda grass, clover, corn, hogs and sheep, home manufactures, &c, &c. Years of toil on the part of our agricultural editors, and other friends of improvement, will be required before much can be effected. I fear that *improvement* and change for the better, have received a sad check from the recent *unfortunate* rise in cotton. It will be the means of materially increasing the already excessive over production.

Let me congratulate you on the improvement you have already effected in the SOUTHERN CULTIVATOR; and urge upon the farmers of Georgia to come out and give us a proper insight into the state of things in that State. Yours, truly,

THOMAS AFFLECK.

Ingleside, near Washington, Miss., April, 1845.

For the Southern Cultivator.

Wool.

MR. EDITOR:—I beg to offer the following statement of the yield of wool from a small flock of *Leicester* sheep which I have just had sheared; and, at the same time, will remark that they have not been once fed during the past winter, having been on a rye lot of 10 acres the whole time.

If any of your reader's flocks can beat the yield, I would be glad to hear from them.

I have a few young Bucks for sale.

Augusta, May 25. B. H. WARREN.

MR. WARREN:—According to your directions, I had sheared last week your twenty *Leicester* sheep. Their yield was 112 lbs. of wool.

The young buck's fleece was 10 lbs.; the old one 7½ lbs. It may be proper to remark, that three out of the twenty sheep were late lambs, and not full grown—so that some allowance should be made for them. Very respectfully,

JOHN W. MORRISS.

Bedford Farm, May 1, 1845.

For the Southern Cultivator.

Tanning on the Plantation.

MR. CAMAK:—I see in your last CULTIVATOR directions for *plantation tanning*, by Mr. Affleck of Mississippi. Having tanned my hides for a number of years, and believing it to my interest, I suppose it will be profitable to others who have many raw hides.

I have succeeded well, and think my leather firmer and more valuable for negro shoes, and the coarse harness on my farm, than tan-yard leather; and as my plan is a much cheaper one than Mr. Affleck's, and as economy is my hobby-horse, I just thought I would ride him out this morning to keep him healthy.

I tan from 10 to 15 hides a year, of various sizes. I have two vats 5 by 7 feet, 4 feet deep, sunk in the ground near a falling branch, so constructed at the bottom that I can draw a plug and wash and empty them. I begin in March; soak my hides ten days in running water. Two or three times I take them out and give them a good rubbing or washing. They are then ready for the lime, as we call it. I then put them in one of my vats, and divide equally among them from 3½ to 5 bushels of good ashes and 2 or 3 quarts of lime, and cover the whole in water.—The lye had better be strong, and if you err, err on that side. Every few days I take them up, or rather stir them up, and mix them again, so that all parts shall be equally acted on by the lye and the atmosphere, in the top and the bottom of the vat. If your ley is right, in 10 or 12 days your hides will be thickened to two or three times their first thickness—feel more like a sheet of jelly than any thing else, and the hair will slip easily. Then slip off the hair, and with a drawing knife or a currying knife, scrape off the loose flesh and cellular matter on the other side, and as much of the lye as you can, without bruising the hide: and then put them back into fresh and clean water. Every other day take them up and give them a good rubbing or scouring, for 10 days. They are then ready for the bark; and by that time you can slip the bark off your oak trees and have it ready for the hides. I never grind my bark. I take it from the tree, and with a drawing knife, take off the rough on the outside, and just beat it enough to cause it to lie flat in the vat. In my other vat I do all my tanning, and commence with a layer of bark, then of leather, and so on; and so lay it in the vat that every part of each side of the leather shall lie against bark; and when I am done, I immerse this entirely in water.

The first year you had better boil an ooze in kettles or pots, and use that instead of water, and afterwards always preserve your old ooze to use next year instead of water. I let this lie until the 1st of August, and put in a second bark precisely as the first, and let it lie until sometime in October or November, when my leather is fully tanned, if these directions have been followed. When the leather is well tanned, it presents a yellow, spongy appearance, through and through; otherwise, you will see a white or hard streak in the centre. When I take it up I scour the ooze well out of all.—That I intend for sole leather, I straighten and dry; that for upper leather, I wash well, then grease well with the cheapest oil I have, and after drying 8 or ten days, I moisten it, curry off the spungy, soft part from the flesh side; and when moist, beat it or break it over some rough surface until it is comparatively soft, and the grain side is all puckered up, or wrinkled into small wrinkles. Then, when my leather is thoroughly dried and shrunk, it is fit for use.

Respectfully, J. S. WHITTEN.

Mount Zion, May, 1845.

For the Southern Cultivator.

Berkshire Hogs.

MR. EDITOR:—When a boy, it was a part of my business to feed the sows and pigs. From habit, or a partiality for "old Ned," or a swinish disposition, I became fond of hogs. This early attachment has not left me. I love to feed them, and to rub them, and to read about them too; in such books, for instance, as the "American Swine Breeder." I give my pigs big names, such as "Sam Jones," "Ben Sherrod," and "Prince Albert." They seem to know their names, and I think are just as worthy of them as some bipeds are to be dubbed General. "*Victoria*" is a favorite name with me. You know she is said to be often "in a delicate and interesting situation," and I like to have her good example imitated. It is the best way to increase the stocks.

While reading the SOUTHERN CULTIVATOR for April, I came to a piece headed "Berkshire Hogs," and signed by "One of the Buckets." Formerly there was a man in this county sometimes called "*Ned* Bucket;" 'tis said he went to Texas and did some tall walking after he got there. This "*One*" may be some of the same family: but—I don't know—people are mistaken sometimes.

"One of the Buckets," it seems, like your humble servant, is fond of hogs, and especially Berkshires. He, like many others, has succeeded finely with them. I am glad that he has. He seems to think that I have *not* succeeded because I did *not* feed them. Now, I suppose Bucket guesses we don't make much corn down this way, and that 'tis *root hog or die.*" Well, I wish he may never be deceived worse than when he thought so.

I recollect reading a long time ago, in some old book, about a man who tried to learn his mare to live without eating. He curried, and brushed, and rubbed, and did all that sort o'thing The poor mare remonstrated, and *told him, food* would do *better without currying*, than *currying* without *food*. Her remonstrances were disregarded, and just as her education was completed, she unfortunately *died*. Some years since, I walked three long summer days, the 4th, 5th and 6th of July, in the woods bordering the Okefenokee Swamp, without meat or bread, or even a "substitute," good or bad.

From what I have read, and from my own experience, I have come to the conclusion that quadrupeds, and bipids too, feel a little more cheerful, and do a little better, when they have good appetites, and a plenty of something good to eat. I have not tried to raise hogs on the wind.

"Bucket" tells some very pretty things about the Berkshires, and I do not doubt a single word he says. He has succeeded finely; "*but mind, he feeds them.*" Ah! *there* is the secret. He does not try to raise hogs without "*corn*," or a "*good substitute.*" That word "*feed*" is a comprehensive term; I *don't understand it*, and would be glad if "Bucket" would explain.

I will just give a short history of "my way," and "Bucket" will be the better able to point out my errors, and others may guard against them also. Heretofore I had fed my hogs in the woods, with corn, turned them on grain fields in summer, on peas and potatoes in the fall, and finished off on a floored pen. I had the scrub stock of the country, with a dash of the Cobbett. I raised plenty of pork and to spare. But I had heard and read about the Berk-

shires. They grew large, had beautiful forms, splendid hams, paid better for their keep than any other breed, and fattened kindly at any age. My hogs generally were not quite large enough. Sometimes one would reach three hundred, but not often. I wanted bigger ones. I must keep pace with my neighbors. Berkshires I must have. An opportunity soon offered. I purchased a pair of pigs of the importer himself, (and a gentleman too,) some of old England's *best*—paid sixty dollars cash—no mistake about it. I had heard something about the Yankee way of cooking and mixing and so on. Well, I thought I *could do* as well as the Yankees, and that I *would do* the thing right. One of Mott's agricultural furnaces was ordered and brought home. A fine steam mill is hard by, owned by clever folks, and very convenient to turn corn into meal. 'Twas not long before I had a hundred or more full blood and half blood Berkshire pigs. It so *happened* we had plenty of corn and potatoes; a fine turnep patch, and more coleworts than we could eat. I had seen some good hogs raised in Georgia, and some good ones brought from Tennessee and Kentucky; I had heard of Dr. S. D. Martin's Woburns, of A. B. Allen's Berkshires, of the Bedford, of the Suffolk, and of the improved Chinese hog, &c., and I intended to raise (for I had of old England's best) just as good as the best. Corn was sent to mill, potatoes dug, vegetables gathered, and Aaron went to cooking. The kettle was filled with corn meal, turneps, or coleworts, and potatoes; water was added, and the whole boiled until thoroughly done. My pigs were fed with this food three times a day, all they would eat. Corn on the cob lay by them all the while. I have now tried the Berkshires four years. I have had plenty of corn and to spare all the time. I have taken more care, and had more attention paid to my hogs, than ever before. They have been kept and fed in the woods and in the field, in lots and in close pens, sheltered and bedded; they have been fed on corn alone, and on corn with "good substitutes," and on raw food and on cooked food. The result is, I have not succeeded; the Berkshires have paid less for their keep than any hogs I ever had.

I wish to be distinctly understood. I do not presume to say the Berkshires have not done well in the hands of others. I am aware they have been highly prized by intelligent and practical men; men of good judgment and of undoubted veracity. I dispute no man's word, and impugn no man's motives. I speak of my own experience and for myself only.

I acknowledge I have not fed Berkshires—to profit. But my friend "*Bucket*"—"*Ah! he feeds his hogs.*" Will he tell me how?

Houston county, April, 1845. CLODHOPPER.

For the Southern Cultivator.

A Freak of Nature.

MR. CAMAK:—*Sir*—The Siamese Twins are a great curiosity, and rendered the more so, as they were a freak of Nature in the human species. I have one to communicate, which I think much greater, and were it not that it is from the brute instead of human nature, it would greatly transcend the former, as to the interest it would excite in the curious. I send this statement to you, and if you think proper, you may give it a place in your CULTIVATOR, not that it is exactly appropriate for such a journal, but that it may interest some of your readers, as many of them are engaged in rearing horses and mules; and because, too, as a subscriber to your valuable paper, I wish to cast in my mite of that which might interest.

On the 29th of March, I had a mare that foaled a mule colt, (or colts, I do not know which to call it,) of full size, though dead when I found it, with two perfect heads and necks coming handsomely out of one perfect body, without any deformity, and each head and neck as large as we would suppose the body ought to have, had it but one. I had it skinned as neatly as I could, and stuffed with bran; and this was done in the presence of Dr. B. F. Rea; and on examination, he found it had two hearts and two stomachs, connected with one set of intestines, thus far forming two distinct organizations, partly separate, as in the heads and necks, then blended in one body, partially through a part of the internal organs, and then strangely united in one, as to the balance, such as intestines, legs, &c. &c.

If any one wishes to see the skin of this strange anomaly of nature, I invite him to call at my house in Greensboro and he can do so, and after my friends have seen it, I propose to have it placed in some well regulated Museum.

Respectfully, yours, &c.

W. W. D. WEAVER.

Greensboro', April 26, 1845.

For the Southern Cultivator.

MR. CAMAK:—In renewing to you the assurance of another year's acquaintance, I felt gratified at the course the CULTIVATOR was taking; and have had one unitorm belief, that it will conduce to the essential interests of Georgia.

Falling over from an honorable profession to agriculture, I wish that my knowledge of medicine could be transferred to agriculture. I wish I could approach the subject with as much confidence as I think I may touching clinical cases. I will promote our interest better by inquiry than an exposition of any imperfect notion I may have in planting, cultivating or gathering.

These three years past the trees in my apple orchard have dropped their fruit from the time it begins to form until it ripens. Now, under the trees, you may find all sizes, from a garden pea to a hickory nut, covering the ground. In March a few of the trees had curled leaves.—The blossoms were yellowish, sickly, and fell off. The balance of the orchard looked thrifty, but the trees are afflicted with the same scourge they have been these three years. Opening the repudiated fruit we find, through all its sides to centre, a dark passage made by some insect, whose form and action the eye cannot discover. In the centre of the apple we find, sometimes, a maggot, but the parent I know nothing of only from its influence. I have read somewhere that by beating the trees in the evening, with cloths spread underneath, the insect might be caught and burned. I have not found it so; and the mischief will go on until the insect gets too weak, or the fruit too strong, to continue the mischief.

Late planted cotton has not come up, and that on dry clay soil is no better. Other well-broken land and early plantings get along better than could be expected from such deep and extensive drouth. The oat crop is cut off—its scantiness was never known before. That sown early is shooting half ancle high—that later, is ashamed to head at all. But relying on the CULTIVATOR's theoretic, we expect yearly to amend our *practiques*, and by acquiring other resources of the State, (which it may be capable of,) to bring us to that state of independence the planters enjoyed in years gone by. I salute the editor with the courtesy of friendship, and trust its guidings may, in future time, be quoted as a standard to better informed agriculturists.

May, 1845. N. CRAWFORD.

EXCRETORY DUCT OF THE FEET OF SHEEP.—Chancellor Livingston, 1st President of the N. Y. State Agricultural Society, says, the legs of sheep are furnished with a duct, which terminates in the fissure of the hoof; from which, when the animal is in health, is secreted a white fluid, but when sickly, the ducts are stopped by the hardening of the fluid. He says he has, in some instanees found that the sheep were relieved, by merely pressing out the hardened matter with the finger from the orifice of the duct in each foot; it may in some cases be proper to place their feet in warm water, or to use a probe or hand brush for cleansing this passage.—*Farmers' Cabinet.*

☞ An hour's industry will do more to beget cheerfulness, suppress evil humors, and retrieve your affairs than a month's moaning.

Agricultural Meetings.

Agricultural Meeting in Chatham.

At an adjourned meeting, held on the 16th ult., at the Court House in Savannah, for the purpose of organising an Agricultural Society, a respectable number of Planters, and others engaged in agricultural pursuits, were present; JOHN LEWIS, Esq. in the Chair, and GEO. P. HARRISON, Acting Secretary. The minutes of the last meeting were read and confirmed.

On motion, the Constitution, adopted at the last meeting, was reconsidered, and after one or two slight amendments, was adopted.

The By-Laws, reported to the last meeting, were then taken up by sections, and after various amendments, were adopted.

The meeting then proceeded to organise the Society, by electing officers under the Constitution.

When the Hon. J. M. Berrien was unanimously elected to fill the office of President, and John Lewis, Esq., of Chatham County, Thomas S. Clay, Esq., of Bryan County, and Clem. Powers, Esq. of Effingham County, were elected to fill respectively the offices of First, Second and Third Vice-Presidents.

The President elect being absent, John Lewis, Esq., First Vice-President, resumed the Chair. The Society then proceeded to fill the remaining offices; and the following gentlemen were elected to the same, viz: George J. Kollock, Corresponding Secretary, George P. Harrison, Recording Secretary, Samuel C. House, Treasurer; Robert G. Guerard, Librarian; and Dr. William H. Cuyler, George Jones, William D. Hodgson, William P. Bowen, and Dr. John S. Law, were elected to compose, with the President and three Vice-Presidents, *ex officio*, the Board of Managers.

It was then, on motion—

Resolved, That the Corresponding Secretary of the Society be directed to subscribe to such a number of copies of the Southern Cultivator as will be necessary to supply each member with a copy, on the best terms that can be done; and also to retain one copy, to be deposited with the Librarian, for the use of the Society.

Resolved, That the Corresponding Secretary, in connection with the Board of Managers, be directed to publish such of the proceedings of this Society as they may deem proper, in the gazettes of this city, and in the *Southern Cultivator.*

On motion the Society adjourned.

JOHN LEWIS, 1st Vice-Pres't.

GEO. P. HARRISON, Rec'g Sec'y.

CONSTITUTION.

Article 1. This Society shall be called "The Agricultural Society of Chatham and adjacent Counties."

Art. 2. Its object shall be to collect and diffuse information concerning Agriculture in all its departments and connections; and to encourage and improve the same amongst ourselves.

Art. 3. The officers of the Society shall be a President, three Vice-Presidents, Corresponding Secretary, Recording Secretary, Treasurer, Librarian, and a Board of Managers, who shall be elected by ballot at each annual meeting. Should a vacancy occur in any of said offices, by death, resignation, or otherwise, it may be filled up by ballot, at the next regular meeting of the Society. And if it should happen in any office other than that of the President or Vice-Presidents, it may be filled up until the next regular meeting by the presiding officer.

Art. 4. There shall be an annual and quarterly meetings of this Society, at such times as may be established by the By-Laws.

Art. 5. The day before the annual meeting of this Society, there shall be an exhibition of Agricultural products, stock, manufactures, and such other things as the Society may choose to encourage.

Art. 6. The President, or in his absence, either of the Vice-Presidents, may call an extra meeting of the Society, upon the request of three members.

Art. 7. Any person wishing to become a member of this Society, may do so, by subscribing to the Constitution, and paying the amount of contribution money, unless objection is made, in which case a majority present may admit him. Each member shall pay an annual contribution of three dollars.

Art. 8. Five members, including at least two officers, shall constitute a quorum, and he empowered to transact the regular business of the Society, except at the annual meetings, when thirteen shall constitute a quorum

Art. 9. The Society shall pass such By-Laws as they may deem necessary to carry out the object of the Association.

Art. 10. This Constitution can be altered or amended only by a vote of two-thirds of the members present at the annual meeting; and a notice to that effect having been given at a previous meeting.

The Constitution of the Society is now in the hands of John Lewis, Esq., first Vice-President, at his office in the Exchange. Those who are friendly to the cause in which we are engaged, and are disposed to unite with us in the effort to improve our Agriculture, are requested to call and sign the Constitution as early as is convenient, as it is of importance that we should have a full list of our members at once.

GEORGE J. KOLLOCH, Cor'g. Sec'y.

Agricultural Meeting in Habersham.

CLARKSVILLE, May 6, 1845.

At a meeting held this day, at this place, by a respectable portion of the citizens of Habersham county, it was resolved that said meeting form itself into an Agricultural Society, and proceed to the election of a President, first and second Vice-Presidents and Secretary—the latter of whom shall be Treasurer.

Whereupon, James R. Wyly was chosen President, George D. Phillips first, and William W. Alley, second Vice-President, and Phillip Martin, Secretary and Treasurer.

When the President elect took the chair, it was resolved that a committee of three be appointed by the chair to draft a constitution and by-laws for the government of said society, to be reported for consideration at our next meeting—whereupon the chair appointed George D. Phillips, John T. Carter and Malcom J. Walker that committee.

Resolved by the meeting, That John W. H. Underwood and Malcom J. Walker be, and they are hereby appointed corresponding Secretaries of this Society.

Resolved, That the chair appoint some member to address the society at its next meeting, on some branch of agriculture—whereupon the chair appointed William B. Wofford, to address the society at its next meeting.

The meeting then adjourned until the first Tuesday in July next.

JAMES R. WYLY, Pres't.
PHILLIP MARTIN, Sec'ry.

Planters' Club of Early.

On the fifth of May, notice being previously given, the citizens of Early met at the court house in the town of Blakely, for the purpose of forming a Planters' Club. On motion of Mr. S. H. Trulock, Major Joel Crawford was called to the Chair, U. Trulock to act as Secretary. After some appropriate remarks from the Chair in the way of explanation, there was appointed a committee of five to draw up articles of constitution, when Maj. J. Crawford proposed to read to the committee articles which he had previously drawn up, which, after being read the second time, were unanimously adopted, and handed over to the Secretary. On motion of Judge William Castleberry, the names were next taken of such individuals as wish to become members of the Club, when some twenty-four gentlemen enrolled their names. It was resolved that each member should, on enrolling his name, pay the sum of fifty cents, to defray the necessary expenses.

On motion of Mr. Reese, it was

Resolved, That it shall be the duty of the President, with the consent of the Vice-President, to appoint a speaker for the regular sessions, which will be the first Thursday in January and May.

The Club then proceeded to the election of officers. Major Joel Crawford was elected President, Judge Wm. Castleberry first and S. H. Trulock second Vice-President, U. Trulock Secretary and Treasurer. On motion,

Resolved, That the Secretary be requested to notify Judge Wm. Taylor that he is chosen to deliver an Agricultural Address at our next meeting, on the first Monday in July next, Maj. Crawford his alternate, and L. Everingham alternate to Maj. Crawford.

Resolved, That the Secretary furnish an account of our meeting to the Fort Gaines Whig, and request its publication therein.

URIAH TRULOCK, Sec'y.

Horticultural Outline.

AN OUTLINE of the first principles of HORTICULTURE, by JOHN LINDLEY, F. R. S. &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.—[CONTINUED.]

VI. FLOWERS.

146. Flowers consist of two principal parts, viz: *Floral Envelopes* (149,) and *Sexes* (VII.)

147. Of these, the former constitute what is popularly considered the flowers; although the latter are the only parts that are absolutely essential to it.

148. However different they may be in appearance from leaves, they are all formed of those organs in a more or less modified state, and altered in a greater or less degree by mutual adhesion.

149. The Floral Envelopes consist of two or more whorls of transformed leaves; of which part is calyx, its leaves being called sepals, and part corolla, its leaves being called petals.

150. The Sexes are also transformed leaves, (187.)

151. The calyx is always the outermost, the corolla is always the innermost whorls; and if there is but one floral envelope, that one is calyx.

152. Usually the calyx is green, and the corolla colored and more highly developed; but the reverse is frequently the case, as in Fuchsia, Ribes sanguineum, &c.

153. A flower being, then, an axis surrounded by leaves, it is in reality a stunted branch, that is, one the growth of which is checked and its power of elongation destroyed.

154. That Flowers are stunted branches is proved, firstly, by all their parts, especially the most external, occasionally reverting to the state of ordinary leaves; secondly, by their parts being often transformed into each other; and, thirdly, by the whorls of flower-buds being dislocated and actually converted into branches whenever any thing occurs to stimulate them excessively.

155. Their most essential distinctive character consists in the buds at the axillæ of their leaves being usually dormant; while those in the axillæ of ordinary leaves are usually active.

156. For this reason, while leaf-buds can be used for the purpose of propagation, flower-buds cannot usually be so employed.

157. Being stunted branches, their position on the stem is the same as that of developed branches.

158. And as there is in all plants a very great difference in the development of leaf-buds, some growing readily into branches, others only unfolding their leaves without elongating, and many remaining altogether dormant, it follows that flower-buds may form upon plants of whatever age and in whatever state.

159. But to produce a general formation of flower-buds it is necessary that there should be some general predisposing constitutional cause, independent of accidental circumstances.

160. This predisposing cause is the accumulation of sap and of secreted matter.

161. Therefore whatever tends to retard the free flow of sap, and causes it to accumulate, will cause the production of flower-buds or terility.

162. And on the other hand, whatever tends to produce excessive vigor causes the dispersion of sap, or prevents its elaboration, and causes sterility.

163. Transplantation, with a partial destruction of roots, age, or high temperature accompanied by a dry atmosphere, training obliquely or in an inverted direction, a constant destruction of the extremities of young growing branches, will all cause an accumulation of sap, and secretions; and consequently all such circumstances are favorable to the production of flower-buds.

164. But a richly manured soil, high temperature, with great atmospheric humidity, or an uninterrupted flow of sap, are all causes of excessive vigor, and are consequently unfavorable to the production of flower-buds.

165. There is a tendency in many flowers to enlarge, to alter their colors, or to change their appearance by a transformation and multiplication of their parts, whenever they have been raised from seeds for several generations, or domesticated.

166. The causes of this tendency are probably various, but being entirely unknown, no certain rules for the production of varieties in flowers can be laid down, except by the aid of hybridising, (210.)

167. It often happens that a single branch produces flowers different from those produced on other branches. This is technically called a sport.

168. As every bud on that branch has the same specific vital principal (113,) a bud taken from such a branch will produce an individual, the whole of whose branches will retain the character of the sport.

169. Consequently, by buds an accidental variety may be made permanent, if the plant that sports be of a firm woody nature, (98.)

170. As flowers feed upon the prepared sap in their vicinity, the greater the abundance of this prepared food, the more perfect will be their development.

171. Or the fewer the flowers on a given branch the more food they will severally have to nourish them, and the more perfect will they be.

172. The beauty of flowers will therefore be increased either by an abundant supply of food or by a diminution of their numbers (thinning,) or by both. The business of the pruner is to cause these by his operations.

173. The beauty of flowers depends upon their free exposure to light and air, because it consists in the richness of their colors, and their colors are only formed by the action of those two agents, (281.)

174. Hence flowers produced in dark or shady confined situations, are either imperfect or destitute of their habitual size and beauty.

175. Double Flowers are those in which the stamens are transformed into petals; or in which the latter, or the sepals, are multiplied. They should not be confounded with *Proliferous* (183,) and *Discoid Compound Flowers* (184.)

176. Although no certain rules for the production of double Flowers can be laid down, yet it is probable that those Flowers have the greatest tendency to become double, in which the sexes are habitually multiplied.

167. In Icosandrous and Polyandrous plants, either the stamens or the pistilla are always very numerous when the flowers are in a natural state; and it is chiefly in such plants that double Flowers occur, when they become transformed.

178. It is therefore in such plants that double Flowers are to be principally expected.

179. In proportion as the sexes of Flowers habitually become few in number, do the instances of double Flowers become rare.

180. Double Flowers are therefore least to be expected in plants with fewest stems.

181. Whenever the component parts of a flower adhere by their edges, as in monophyllous calyxes, monopetalous corrollas, and monodelphous, or polyadelphous stamens, the tendency to an unnatural multiplication of parts seems checked.

182. Therefore in such cases double Flowers are little to be expected; they are, in fact, very rare.

183. Proliferous Flowers are those in which parts that usually have all their auxiliary buds dormant, accidentally develop such buds; as in the Hen and Chickens Daisy, in which the bracteæ of the involucrum form other Daisy-heads in their axillæ; or, as in certain Roses, in which the capillary leaves develop leaf-buds in their axillæ, so that the flower becomes a branch; the lower leaves of which are colored and transformed, and in their ordinary state.

184. Discoid compound Flowers are those in which the central florets of a flower-head acquire corollas, like those of the circumference, as in the Dahlia; the cultivated variety of which should be called discoid, and not double.

185. These two last are so essentially different from double Flowers, that whatever laws may be supposed to govern the production or

amelioration of double Flowers, can have no relation to proliferous or discoid Flowers.

VII. SEXES.

186. The sexes consist of two or more whorls of transformed leaves, of which the outer are called *Stamens* (188,) and the inner *Pistillum*, (191.)

187. They are known to be modifications of leaves, because they frequently are transformed into petals which are demonstrably such (149,) and because they occasionally revert to the state of leaves.

188. The stamens bear at their apex an organ, called the *anthor*, which contains a powder called *pollen*.

189. When the anthor is full grown it opens and emits the pollen, either dispersing in the air in consequence of the elasticity with which it opens; or depositing it upon the stigma (191,) or exposing it to the action of wind, or such other disturbing causes as may liberate it from its case.

190. The pollen consists of exceedingly minute hollow balls, or cases, containing myriads of moving particles, which are the fertilizing principle of the stamens.

191. The pistillum has at its base one or more cavities or *cells*, in which bodies called *ovula* are placed; and at its apex one or more secreting surfaces called *stigmata*.

192. The ovula are the rudiments of seeds.

193. If the fertilizing powder of the pollen come in contact with the stigma, the ovula in the cells of the pistillum are vivified, and become seeds.

194. But if this contact does not take place the ovula cannot possibly be vivified, but shrivel up and perish.

195. The phenomenon of vivification takes place in consequence of the descent of a portion of the moving particles (190) of the pollen into the ovula, where such particles form the commencement of future plants.

196. In wild plants a stigma is usually acted upon only by the pollen of the stamens which belong to it.

197. In this case the seeds thus vivified will, when sown, produce new individuals, differing very little from that by which they were themselves produced.

198. And, therefore, wild plants are for the most part multiplied from generation to generation without change.

199. But it is possible to cause deviations from this law, by artificial means.

200. If the pollen of one species is placed upon the stigma of another species, the ovula will be vivified; and what is called a *hybrid* plant will be produced, by those ovula when they shall have grown to be seeds.

201. Hybrid plants are different from both their parents, and are generally intermediate in character between them.

202. They have little power of perpetuating themselves by seeds, but they may if woody be perpetuated by cuttings (312,) buds (354,) scions (335.) &c.

203. Therefore, no hybrids but such as are of a woody perennial character can be perpetuated.

204. It usually happens that the hybrid has the constitution and general aspect of the polliniferous parent; but is influenced in secondary characters by the peculiarity of the female parent.

205. This should always be borne in mind in procuring new hybrid plants.

206 Really hybrid plants must not be confounded with such as are spaceous, in consequence of their origin being between two varieties of the same species, and not two species of the same genus.

207. Hybrid plants, although incapable of perpetuation by seed, are often more abundant flowerers than either parent.

208. This is probably connected with constitutional debility, (162.)

Pennyroyal, it is said, if woven in their nests, will protect hens from vermin.

JASSIMINE.—The *Jassimine* is celebrated more for the delicacy of its odor and flowers, than for the pretty love legend connected with its European history. The custom which prevailed in some countries, of brides wearing Jassimine flowers in their hair, is said to have arisen from the following circumstance: a grand duke of Tuscany had, in 1699, a plant of the deliciously-scented Jassimine of Goa, which he was so careful of, that he would not suffer it to be propagated. His gardener, however, being in love with a peasant girl in the neighborhood, gave her a sprig of this choice plant on her birthday; and he having taught her how to make cuttings, she planted the sprig as a memorial of his affection. It grew rapidly, and every one who saw it, admiring its beauty and sweetness, wished to have a plant of it. These the girl supplied from cuttings, and sold them so well as to obtain enough money to enable her to marry her lover. The young girls of Tuscany, in remembrance of this adventure, always deck themselves on their wedding day with a nosegay of Jassimine, and they have a proverb, "that she who is worthy to wear a nosegay of Jassimine is as good as a fortune to her husband."—*Western Cult.*

SUBSOIL PLOWS.—In many soils, not otherwise rich enough for corn, it would be a good practice to make a furrow six inches deep, in the fall with a common plow, then let a subsoil plow run in this furrow ten or twelve inches more; and it would be still better to put cornstalks and other manure in this trench, and list it in, when thoroughly wet, with a small plow or hoe; the land to remain in this state till planting time. The subsoil plow is valuable; by its use the soil will be less wet in great rains, and more moist in great drouth. Where the subsoil plow is used, in

comparison with only the common plow, the yield will be fifty per cent. more, and the crop in dry weather always green. The subsoil plow has doubled and frequently trebled the crops in England.—*Farmer and Gardener.*

Cotton Beds.—A Good Suggestion.

We find the following in the Albany Cultivator Cotton beds are becoming very much in use on steamboats on the Western rivers, and they are considered superior to any kind but hair:

Cotton Beds.—We have received from J. A. Guernsey, Esq., a copy of the "Southron," published at Jackson, Mississippi, containing some remarks on the advantages of cotton for bedding. These advantages may be summed up as follows. It is claimed that "it is the cheapest, most comfortable, and most healthy material for bedding, that is known in the civilized world." In addition to these, may be named *superior cleanliness;* vermin will not abide it: there is *no grease* in it, as in hair or wool; it does not get *stale* and acquire an *unpleasant odor*, as feathers do; moths do not infest it, as they do wool; it does not pack and become hard, as moss does; nor does it become dry, brittle and dusty, as do straw or husks; and in many cases *medicinal.*" It is said not to cause that lassitude and inertia, which is produced by sleeping on feathers. People not acquainted with it, have supposed they have been sleeping on the best feathers, when in fact their beds were made of cotton. The relative cost of cotton compared with feathers, hair, &c., may be seen from the following statement:

Cost of a Hair Mattrass.—They are generally sold by the pound and cost from 50 to 75 cents per pound. Thirty or forty pounds will cost $15 or $20.

Wool.—Thirty pounds of wool at 30 cents per pound, $9; twelve yards of ticking at 12½ cents per yard, $1 50; labor, thread, &c., $2 75. Total, $13 25.

Feathers.—Forty pounds feathers at 30 cents per pound, $12 00; fifteen yards of ticking at 12½ cents per yard, $1 87½; labor, &c., $2 75 cents. Total, $16 62½.

Cotton.—Thirty pounds cotton at 8 cents per pound, $3 40; twelve yards ticking at 12½ cents per yard, $1 50; labor, thread, &c., $2 75. Total, $7 65.

It is recommended to run the cotton through a "picker," where one can conveniently be obtained, before using. This gives it additional cleanliness and buoyancy.

The substitution of cotton for bedding throughout the United States would be an immense saving, besides opening a new avenue for that article to an extent according to the estimation of this writer, equal "to more than two of the largest crops of cotton ever produced in the United States."

Dig Deep and you'll find Treasure.—We commend the following anecdote to the particular consideration of those who are yet addicted to the practice of shallow plowing, and who think that no good comes from deep stirring of the soil. By adopting the practice of deep plowing, a new source of wealth would be opened on many farms, which the "*skinning*" culture of a century or two had never developed. But to the anecdote—which, though old, is just as good as if it were "bran new:"—

"An old farmer, on his death-bed, told his sons, who were not very industrious lads, that he had deeply buried his money in a particular field, which was the most barren land on his farm. In consequence of this information, soon after the old man's death, the sons began to dig (and they dug deeply too) all over the field—and this they did again and again, for it was long before they quite despaired of finding the money. At length, however, they gave up the search, and the land was planted with corn; when, from the deep digging, pulverization and clearing which it had received in the search for the money, it produced a crop which was indeed a treasure."

It might result to the profit of some of our farmers' sons, should they imagine their fathers had deeply buried a bag of dollars in some barren field, and be led to dig in search of the treasure—and though they might not find the expected wealth, their exertions would be amply rewarded, as is illustrated in the anecdote.—*N. E. Farmer.*

VOL. III. AUGUSTA, GA., JULY, 1845. No. 7.

PENDLETON AGRIC'RAL SOCIETY.

REPORT OF THE COMMITTEE ON FARMS, MADE TO THE SOCIETY ON THE 10TH OCTOBER, 1844.

Mr. Thomas M. Sloan's Farm.—The Committee commenced their operations by visiting the farm of Mr. Thomas M. Sloan on the 16th of September. This farm consists of about one hundred and thirty acres of low grounds, on the Seneca river, and as much, or a greater number of acres of good upland. It has always been regarded as one of very great value, not only by reason of the great natural fertility, but also durability of its low grounds.

The Committee have not been able to decide upon its present, compared with its former, productive powers; but judging from the evidences presented to them, by the heavy crop of corn and pea vine now upon the land, they are of opinion that the management of the proprietor has been at least such as to enable him to reap a rapid succession of abundant crops for the last twenty years, without materially impairing its value.

This, however, is only applicable to the low grounds: the upland fields have not fared so well. Either by reason of a too rapid succession of tillage crops, or by the total neglect of guard drains, or in all probability both, a portion of the upland fields have shared, to some extent, the fate so commonly attendant upon our agricultural operations, of being washed into gullies, and otherwise materially impoverished.

The Committee were gratified to discover that Mr. Sloan has become fully awakened to the importance of the subject; has recently constructed several guard drains by way of experiment; and seems determined to extend them as far as may seem necessary to the safety of his upland fields.

So far as his uplands are concerned, the proprietor has adopted a rotation consisting of a tillage crop and a small grain alternately. On the low grounds, he informed us he was in the habit of cultivating two successive tillage crops, and every third year a crop of small grain.

Mr. Sloan regards the pea crop as one of very great value. We found it co-extensive with his entire corn crop: and although large quantities are gathered annually as provender for stock, yet a still greater quantity must necessarily be returned to the soil, and to this, as a principal cause, the Committee are disposed to ascribe the durability of these low grounds, together with that of several other farms, similar in all respects to the one under consideration.

The crop on this farm was good throughout, and consisted of an equal number of acres of corn and cotton. The quantity to the hand was fourteen acres, exclusive of small grain.

The wheat crop was said to be good, and far beyond the quantity required for domestic consumption. The hogs were very fine, principally of the Berkshire breed. The cattle were not seen by the Committee. The farm houses, consisting of stables, corn cribs, cow houses, &c., were very good, and the horses in good condition.

The last object to which the attention of the Committee was directed, was an excellent grist mill, a very superior threshing machine, a cotton gin, a cutting machine, a corn sheller, and a corn crusher, all under one roof, and capable of being employed at the same time, or separately, as desired.

The Committee were much pleased with this extraordinary combination of mechanical and laboring operations. They regard this establishment not only as one of great convenience but of profit also.

In conclusion, the Committee, after all they have seen on this farm, have come to the conclusion, that Mr. Sloan is a successful planter; and from the amount of old corn, and other evidences of abundance which every where met the eye, they have no doubt but that if famine should desolate our fair country in his day, he will be one of the last survivors.

Mr. Robert A. Maxwell's Farm.—This farm, like the preceding, is one of very great value, consisting of extensive low grounds, of remarkable fertility, and of a still larger amount of upland. The low lands were exclusively appropriated to the culture of corn, intermixed with peas, and the uplands to the cotton crop.

The Committee have no data on which to base a calculation as to whether this farm has improved or degenerated. But from the acknowledgment of the proprietor, that his operations, especially on his low grounds, had not been governed by any regularly established rotation, the Committee are disposed to infer, notwithstanding the crop was highly superior throughout, that his efforts heretofore have been directed more towards the maintenance of its general productive powers, than to any great improvement of them. Necessity is a stern law, and one whose requisitions are most commonly complied with. But a habitual reliance upon resources that never fail, and never deceive us, is apt to lull the mind into a state of apathy, if not false security, which cannot fail to retard our progress in the prosecution of agricultural enterprises and improvements.

The Committee are firmly of the opinion, that after witnessing the low grounds, not only on Mr. Maxwell's farm, but also those on the other river farms which they have examined, and with a full knowledge of their great recuperative powers, that the adoption of a more lenient rotation, in connection with other auxiliary means, would refresh and enrich the low grounds rapidly, and at the same time increase the annual profits of the planter.

The Committee were gratified to discover that the proprietor, as if sensible of the importance of this policy, had under way an experiment with the red clover, covering an area of thirty acres, and intended in due time to be given to the land, which though unpromising, by reason of the extraordinary drought that had afflicted the country during the latter part of the season, may, nevertheless, under more favorable circumstances, prove a source of interest as well as profit to the owner.

The Committee were also informed by Mr. Maxwell of an experiment, the result of which when completed, he has promised to lay before the Society, that will no doubt prove a source of interest as well as of instruction, to all who are interested in the important business of reclaiming waste and worn out lands. This experiment was made upon a field thickly set with sedge grass, which was first turned in, and will be followed this fall with a crop of rye, to be also given to the land, with peas, to be in due time applied in the same way.

The attention of the Committee was also drawn to an experiment at manuring a very exhausted piece of land with leaves spread upon the surface and plowed in, with a spade full of swamp mud to each hill. The result when compared with a portion of the same field not thus managed, was said to be the difference between an ear and a nubbin. But as Mr. Maxwell has furnished a reply to the interrogatories addressed to the several competitors, in which this experiment will be fully detailed, the Committee decline offering any further observations on the subject.

In the cultivation of the uplands upon this farm, which are exclusively appropriated to cotton, the proprietor has illustrated in a very satisfactory and convincing manner, the advantages of horizontal plowing, or that near approach to it, which provides that each furrow shall convey away its own superabundance of water, and yet so gently as to leave the soil behind.

This object has been fully accomplished by Mr. Maxwell, with the exception of a few points, throughout a cotton crop of more than one hundred acres. And although a considerable portion of these lands have been in cultivation for many years, and some of them consist of steep hill sides, yet no gullies were seen by the Committee, or other proof of material injury from washing away of the soil.

In the business of guard drains, Mr. Maxwell has not yet embarked. But so thoroughly has he become convinced of their indispensable importance, that we have every reason to expect that by the next anniversary of our Society, through a combination of guard drains and intermediate horizontal culture, this farm will exhibit unquestionable proofs of refined agricultural operations.

As to manuring on this farm, the quantity made, and the manner of making and applying it, the Committee beg leave to refer to the reply to the interrogatories.

The stock of horses exhibited to the Committee were of good quality, though not in fine condition, owing no doubt to the fact that the proprietor assigns a greater number of acres to each plow horse than is usually done. The cattle were very fine and of improved breed.—The hogs were also highly superior, and generally of the Berkshire breed. And here the Committee beg leave to state a fact which has a material bearing upon the important question as to the relative merits of the Berkshire and the original stock of the country, (alias land pikes.) A lot of the common stock, some eight or ten in number, about equal in age, and reared under equally favorable circumstances, with a much larger lot of Berkshires, were closely observed by the Committee; the contrast was most disparaging to the native breed; they were not only much smaller, but evidently much less thrifty.

As to the agricultural implements on this farm, they were sufficiently numerous and of good quality, and the same merit was considered due to the negro and other farm houses, with but few exceptions.

Hon. J. C. Calhoun's Farm.—The Committee next proceeded to examine the farm of the Hon. John C. Calhoun, and although it may be truly said that nature has done much for it, yet to its proprietor clearly belongs the merit of very superior management.

Acting upon the theory, that lands possessing the greatest natural fertility, must ultimately become exhausted by a too rapid succession of tillage crops, without some adequate return; and from the destructive effects of washing

rains, Mr. Calhoun seems to have found a resource for the former, in the cultivation of the pea crop, and for the latter, in the application of guard drains to his upland fields, evidently equal to the necessities of his position in both respects.

The Committee are of opinion, that the evil of greatest magnitude, and the one which more than all others combined, tends to frustrate our agricultural operations, and impoverish our fields, is that which we suffer from heavy falls of rain, and the consequent washing of our lands. It is true, that tillage does its part, especially when unconnected with a rotation of crops, tending to give rest, and impart refreshment to the soil. But compared with the other mischief, it is but as the drop in the bucket.—To this, as a principal cause, is to be ascribed the almost incalculable amount of worn out and waste lands, and yawning gullies, which disfigure and disgrace almost every farm that meets the eye throughout our country. It is this ruinous tendency, unchecked by a single contrivance, but as tamely submitted to as if it were one of the irresistible decrees of destiny, which has led to the suicidal policy of abandoning fields as soon as their original fertility became exhausted, and felling the forest in search of the means of further subsistence; and finally, it is this which has caused so many thousands of our countrymen to exchange "their own, their native land," with all its tender endearments, for the toils, privations and dangers of our western frontier.

Deeply impressed with the importance of this subject, the Committee were both gratified and instructed by the extraordinary management of Mr. Calhoun, by which, through the instrumentality of guard drains on all his upland fields, placed at such distances apart, and graded in such strict conformity to hydrostatic principles, that his upland fields, even those of the greatest declivity, have sustained almost as little injury from the heaviest falls of rain, as the rich low lands at their base.

The Committee are aware that such a statement is likely to be regarded as the offspring of that enthusiasm in reference to agricultural enterprises and improvements, which well directed experiments too often prove to be fallacious.—But regarding the farm of Mr. Calhoun as the first, if not the only one, in this section of our country, upon which this policy has been fully illustrated, and as furnishing proof approaching to mathematical certainty, of the facts stated by the Committee, they have deemed it a duty incumbent on them, to bring to the notice of our planters, not only the principles upon which this measure has been conducted, but also the results which have followed.

Their attention was first directed to Fort Hill, a field of about forty acres, terminating at its base on the one side, in the low grounds, and connected with the uplands on the opposite side, by a depression considerably lower than its summit. This field, by reason of its descending in every direction, necessarily required to be literally belted with guard drains. Certain points appeared to have been selected, at which the water could be discharged with the greatest safety, and a series of drains were directed round the hill, with a descent just sufficient to convey away the water, and yet so gently as not to enlarge or deepen their channels. The number of these drains was made to correspond with the necessities of the field, as determined by the amount of its declivity, being more numerous and nearer each other where the descent was greatest.

The Committee were not informed as to the amount of this descent, or deviation from the horizontal line. But judging from the eye, they were supposed to equal from three to five feet in the hundred yards.

As a further measure of precaution, the intermediate drill rows were run out horizontally, or nearly so: an arrangement which, by the aid of the first great measure of safety to the soil, seemed to have enabled each furrow to retain its own water, or to have parted with it so gradually as not to leave a trace of the slightest injury.

The Committee did not learn how long this celebrated hill had been in cultivation, though appearances justify the conclusion that it must have been cleared thirty or forty years; yet, notwithstanding the soil was evidently good originally, judging from the very heavy crop of corn and pea vine now upon the land, the Committee are induced to believe its productive powers have scarcely diminished.

In other hands, or even in the hands of the proprietor himself, had the above precautionary measures been omitted, the field must ere now have exhibited in many places a series of gullies and abraded surfaces, and been destined soon to take rank with the waste and worn out lands of our country.

The remaining portion of the uplands on this farm, with the exception of various patches in the vicinity of the homestead, were appropriated to cotton. And although the greater part of them was fresh land, that had been but a few years in cultivation, yet, fully impressed with the importance of upland drains, and acting upon the policy that it were easier to prevent than to remedy an evil, a sufficient number of them to protect the lands have been already made, with the same caution, and with the same success attendant upon those on Fort Hill.

The amount of land required for these drains is very inconsiderable, and the amount of soil conveyed away through them, though comparatively small, may often be diverted, as we saw it done in several instances on Mr. Calhoun's farm, to some impoverished spot which would be improved, or to some wet depression which they would elevate and reclaim.

The low grounds on this farm were exclusively appropriated to the corn crop, intermixed with peas throughout. The corn crop was very fine, and the entire surface of the earth was covered with the most luxuriant crop of pea vines we ever witnessed.

By reason of Mr. Calhoun's absence, the Committee are uninformed as to his management of the pea crop, nor do they know any thing concerning his rotation of crops. But all concur in the opinion that a return annually to the soil, of the vast amount of pea vines on each acre of land, would amount to an adequate compensation for all that is taken from it by the corn crop.

The stock on this farm, consisting of horses, hogs and cattle, were of good blood and in fine condition. The farm houses were sufficiently numerous, and both comfortable and convenient. And this was more especially the case with the negro house, which consisted of a building of stone of superior masonry, two hundred and ten feet in length, divided into aparments, with separate fire-places, sufficiently large for all the purposes of comfort and healthful ventilation.

The Committee, in conclusion, have no hesitation in pronouncing the management upon this farm highly superior. The useful and the ornamental have been most happily blended, not only throughout the principal tillage crops of the farm, but also the more refined horticultural operations of the homestead.

Mr. A. F. Lewis's Farm.—The Committee next proceeded to examine the farm of Mr. Andrew F. Lewis; and in justice to this gentleman, and in advance of any remarks in reference to his agricultural operations, they regard it as their duty to state that he is the youngest planter belonging to the list of competitors.—But although he became the proprietor of a landed estate of very great value, only three years since, he has, in that short period, given the most satisfactory proof that he possesses an amount of agricultural skill and enterprise that entitles him to rank with our most experienced planters.

His farm, like the preceding, lies upon the Seneca river, and consists of nearly equal parts of low grounds and good upland. And although a considerable portion of the latter had been neglected for several years previous to his occupancy of them, and overrun with sage, noxious weeds and shrubs, yet the whole has been reclaimed during this short period, and a good crop of corn and pea vines now occupies this hitherto unsightly waste.

In addition to the above improvement, the Committee consider Mr. Lewis entitled to much credit for an extensive and successful application of the spade to the drying of a portion of his low-grounds, heretofore too wet for cultivation.

The corn crop on this farm was confined principally to the low grounds. And although the pea crop was not co-extensive with the entire corn crop, yet they had been very judiciously cultivated with the corn on the uplands, where they were most needed as manure; and a portion of the low grounds exhibited them sown broad cast at the last plowing, in a state of uncommon luxuriancy.

The cotton crop, as on the preceding river farms, occupied the whole or nearly all of the upland fields. And here, again, the Committee had the pleasure of witnessing the salutary effects of guard drains, to a considerable extent. They were planned and executed in a way similar to those described on the farm of the Hon. John C. Calhoun, and with results both gratifying and successful.

The stock of hogs on this farm was of the most improved breed, and at least equal to any we have seen. The cattle were also very fine. As to the horses, they were not only very fine, but in superior condition. The Committee have no hesitation in awarding to Mr. Lewis the credit of having surpassed all his competitors in this important branch of domestic economy.

The farm houses were uniformly comfortable and convenient, and the agricultural implements of good quality.

Dr. O. R. Broyle's Farm.—The farm of this gentleman was next examined. The proprietor has had possession of it only four years.—At the time it came into his hands, it was regarded as an upland farm principally, though there was attached to it, of creek and branch low grounds, very wet, and of equivocal value, probably one hundred acres.

The proprietor, acting under an impression long entertained by him, that the swamps and morasses of our district needed nothing but effective draining to make them not only very productive, but also very durable, has planned and executed the most extensive operations in ditching, and has succeeded in reclaiming, in a more effectual manner than has been done on any other farm known to the Committee, almost his entire low grounds, and has exhibited a crop of corn rising out of bogs heretofore impassable in many places, equal to the most productive low grounds on the Seneca river.

The operations of the proprietor on these low grounds, and their productiveness, believed to be the consequence of thorough draining, are well calculated to teach an instructive lesson concerning the value of the many thousands of acres of swamp lands in the upper districts of the State, and an equally valuable one as to the means necessary to bring them into cultivation.

The Committee were also pleasurably entertained by examining a crop of rice on this farm, of the most astonishing luxuriancy, and judging from the appearance of the present crop, and from the amount reported from one acre on this farm by a Committee of the Agricultural Society last year, they entertain no doubt but that rice may be grown as successfully in this district, as in any portion of the southern States.

The crop of corn on this farm was equal, or nearly so, to that of the other competitors, and the cotton crop, though comparatively small, was generally good.

The farm houses, though new, and some of them unfinished, will be comfortable. The horses were in good condition, but the remaining portion of the stock, consisting of hogs and cattle, were not generally of improved breed, and decidedly inferior to the fine specimens exhibited on the other farms.

Maj. R. F. Simpson's Farm.—This farm is the only one examined by the Committee that is exclusively of upland. And although it contains large bodies of creek and branch bottoms of great fertility, as yet some ten or fifteen acres have been imperfectly dried, but which, notwithstanding the unfavorable circumstances of the experiment, made quite a satisfactory yield.

This farm, when it came into the hands of the proprietor, some seven or eight years since, though once very fertile and productive, had been materially injured by the bad management of a succession of overseers, whose known rule of operations is to make the greatest possible yield to the hand, without the slightest regard to the preservation of the land.

For this reason the proprietor found it to be his first duty, as it was his best policy, to set at once about the important business of repairing injuries imposed upon him by the improvidence of others.

In pursuance of this policy, and stimulated by the necessities of his position, Major Simpson embarked at once in the business of guard drains, as a work of paramount importance, and has continued his operations in this respect until they occupy a position in every field on his farm.

Under this management, a considerable portion of the old lands on this farm have improved, and promise ere long to be restored to their original fertility.

The corn crop on this farm was very good, considering the drought, which is commonly most injurious on upland. The cotton crop was also very good, and no doubts were entertained by the Committee, but that both corn and cotton crops had been well cultivated.

The negro and farm houses on this farm were sufficiently numerous and comfortable.—The horses were in good condition. The hogs and cattle, though not generally an improved breed, were good specimens of the native stock.

Col. John E. Calhoun's Farm.—As the last of their official duties, the Committee proceeded to inspect the farm of Col. John E Calhoun, consisting of an immense body of upland, and of several hundred acres of low grounds, at the confluence of the Keowee and Twelve Mile Rivers. These lands possess, in the opinion of the Committee, a greater depth of soil, and higher productive powers, than any they have examined. And this, together with its superior improvements in buildings, of every kind, from the dwelling house down to the stables and farm houses, make this one of the most valuable farms in the upper country.

Such being the advantages of Col. Calhoun, the Committee have been at a loss in assigning him his position, and defining his merits as a farmer, because it involved the necessity of discriminating between what was due to nature, and what to art.

A good crop, with most planters, is only looked for as a compensation of much toil, and preliminary preparation. But a good crop, with Mr. Calhoun's advantages, is the almost certain consequence of simply planting the land, and cultivating it in the ordinary way.

The condition of this gentleman, (and the remark applies with nearly equal force to the other river planters,) is similar to that of an executive or judicial officer with a fat salary for life. The certainty of an annual stipend beyond the reach of contingencies, is apt to abate to some extent that zeal in the discharge of their official duties so well secured under a different policy by the exercise of the elective franchise.

It is true their lands are rich, and produce annually very abundant crops, but possessed as they are of the most astonishing recuperative powers, and producing as they do, the so called clover of the south, with unsurpassed luxuriancy, it is a matter of some astonishment to the Committee, that these low lands have not been improved, even beyond their present productive powers. It is a governing maxim with many, to "be content with doing well." But although it contains a moral of a highly conservative character, in reference to most of our operations, yet it is wholly inapplicable to agricultural enterprises. It is true there may be a point beyond which the power of production cannot be extended, but that furnishes no excuse, even on the score of personal interest, why all due efforts should not be made to reach as near that maximum point as possible, at least by means so cheap and available as those alluded to.

The crop of both corn and cotton on Colonel Calhoun's farm was superior throughout, and had evidently been well cultivated.

In respect to guard drains, now so generally esteemed of indispensable importance, Colonel Calhoun has not yet engaged. But in the business of horizontal or grade plowing, he has displayed a management that has been most flatteringly signalized by success. He exhibited large fields of hilly land, which, though they had been long in cultivation, showed but slight traces of those destructive evils attendant upon a neglect of this salutary precaution.

The Committee, as has been before observed, regard the farm houses, stables, and other out buildings on this farm, as decidedly superior to any they have witnessed. And the stock of hogs, horses, and cattle, as far as seen by them, of good quality, and, with few exceptions, in good condition.

In addition to the common farm horses, the Committee had the pleasure of examining Col. Calhoun's stock of blooded horses, which claim their genealogy from the most renowned champions of the turf, both in England and the U. States.

In conclusion, the Committee beg leave to state, that actuated by no motive but that of a zealous wish to do their duty, and to gain all the information in their power in respect to the policy of our best planters, with the view of laying the same before our fellow-citizens, that it might become the common property, and thereby add to the general prosperity of the community at large; they have not only visited the farms of all the competitors, but have closely scrutinized their plans, practical operations, and general management, with but slight and unavoidable omissions. And after an attentive survey of the whole ground, we honestly believe that we live in the midst of an agricultural community, whose pretensions would not be disparaged by a contrast with any, even the most improved sections of the State. And although our present progress, compared with what it should be, is but as the dawn that precedes the meridian sun, yet, unless the Committee have been completely deceived by the evidences before them, there is a spirit of improvement abroad in the land, owing in a great degree to the zeal and efficiency of the presiding officer of the Society, which, directed by the lights that modern science has thrown upon our pathways, cannot fail in due time to reclaim the declining fortunes of our country, and counteract the downward tendency of those destructive measures which have so long disgraced our agricultural operations.

In approaching the last act assigned to the Committee by the Society, that of awarding certain specified premiums, to the proprietors of the first, second and third best managed farms, the Committee beg leave to be discharged from the performance of that very delicate and responsible duty. The reasons which have led them to this conclusion, are based upon the fact, that the claims of some three or four of the most prominent competitors are so nearly balanced, that a discrimination in favor of either would be wholly gratuitous and inconclusive. And secondly, that notwithstanding the visiting Committee, as appointed by the President, numbered six besides its Chairman, the services of only three have been made available in visiting all the farms. A circumstance which has thrown the responsibility of deciding this delicate question on a much smaller number than was intended.

The Committee, as their last, but in no wise least duty, feel themselves called upon to express their unfeigned admiration of the superior management of those departments of the homestead proper, over which our kind hostesses, the farmers' wives, have undivided control. For although the farmers themselves have filled their barns and granaries to repletion, and crowded their stock pens with Durham cattle and Berkshire hogs, they have only furnished the raw material. And to their better halves belongs the surpassing credit of those matchless culinary preparations, and horticultural operations, which have so amply compensated the toils of the Committee, and established for themselves the most undoubted claims to the credit of superior domestic management. All which is respectfully submitted to the consideration of the Society.

O. R. Broyles,
R. A. Maxwell,
Thos. M. Sloan,
Andrew F. Lewis.
R. F. Simpson.

ADDRESS OF COL. McDONALD.

Before the Agricultural Society of Barbour county, Ala.

Gentlemen:—In considering the subject of Agriculture, we find that so much has been written of late years, that every point seems occupied; that the whole ground has been so taken up by the first agriculturists of the country, and the greatest statesmen of the age, such as Buel, Colman, Seabrook, O'Neal, Webster, McDuffie and Rives, who have all appeared before the American people as the advocates of agriculture, with a host of others, that we may well despair of bringing before you much that will be new or interesting. It however becomes our duty to press home the subject, to give line upon line, and precept upon precept, however conscious we may be that many of our suggestions will fall still-born from our lips. The earth every where abounds with the elements of human happiness and comfort. To man has been consigned by his Creator the capacity and duty of cultivating the earth; and it has been wisely ordained, that in the proportion as he discharges his duty, in that proportion is he prosperous, happy and comfortable.—The cultivation of the earth was the first employment of man. It is still the great business of all civilized nations, and particularly so in our country. It must ever remain so. It is alike necessary to our health, our comforts, our wants and our happiness. All other arts and employments are dependent upon and have grown out of agriculture. They are necessarily dependent upon it for support and existence.

If agriculture were to cease, all other arts and trades would fail. The face of the earth would again become a wilderness and man a savage. A survey of the present condition of the globe will show us, that nations are enlightened and prosperous, in proportion to the improved or neglected state of agriculture, and that other arts of useful industry prosper or decline, as this parent art is productive or unproductive. Spain, Italy, Asia Minor and Egypt, have in turn been the granaries, in a measure, of the civilized world. While their agriculture flourished, they were prosperous and powerful; but as the agriculture of those countries declined, their energies were broken down, and their population have become poor, miserable objects of pity. Farmers and mechanics form the great body of our population. Their labors constitute the principal source of the wealth of this country; consequently all and every thing that can be done to render their labor more profitable, is adding to the amount of human happiness. The illustrious Franklin, who sustained towards his country the honorable appellation of mechanic, patriot, statesman and philosopher, has pronounced agriculture the most honorable of all employments, being the most independent. The farmer, says he, "has no need of popular favor, nor of the favor of the great, the success of his crops depending only on the blessing of God and his own industry."

In speaking of the farmer, we mean all who cultivate the soil. Whether he be called planter or farmer, we look upon them as belonging to the same class: we regard them as brothers, though geographically separated from each other; and no matter if one should raise rice and cotton, another corn, another wheat, another sugar, another tobacco, they are all agriculturists—all equally dependent upon the bounty and goodness of their Creator. Gentlemen, we have every inducement to exert all our energies in the cause

in which we are engaged—the improvement of the agriculture of our interesting section of country. We have cast our lots in one of the most desirable portions of the United States, for while we can raise by proper attention every product that can be produced in more northern regions, we can, in our mild climate and vigorous soil, raise many valuable and highly important products that cannot be produced where the winters are long and the summers short. In speaking of different sections of country, I believe, however, that the Almighty has distributed his blessings with an impartial hand. Although I know it has been common for gentlemen in addressing Agricultural Societies, to claim for some particular sections of country advantages over other sections, my opinion is, that wherever you find the industrious, prudent, careful farmer, whether he reside in the North, South, East or West, there you will find the happy man.

Those of us that are old enough to recollect the state of agriculture forty years past in the South, and compare it with what it is at the present time, must see the most striking improvements. At that day, the entire crop of small grain was cut down with the old fashioned sickle. A man would have been driven from the field that would have attempted to introduce the cradle into a wheat field, in the upper parts of Georgia. I have often seen twenty reapers at a time taking down the narrow swarth. It was considered a breach of the rules of that day, that three heads of wheat should be found to reach each other after the reapers had passed over the field. Fifty pounds of cotton was considered a good day's work for a hand to pick out. Our valuable southern staple was then packed, or rather pounded, into a round, unshapely bag, and, if it had been ever so nice, it was so saturated by throwing water into the bag to enable the packer to get in some cotton, that the cotton was measurably spoiled before it left the gin. We then hauled it from one to three hundred miles on wagons. I have known it hauled with a four horse team from Georgia to Virginia. The plow we then used was the old fashioned cutter, the common shovel, and the heavy and awkward bar-shear. Twisted *raw hide* was used to a considerable extent in the place of the trace chain. Tobacco, which was then extensively cultivated in the upper part of Georgia, was tumbled over, or rather rolled through, the mud hundreds of miles to market, under the appellation of the rolling hogshead; it often being a matter of much doubt, after reaching the market, whether the tobacco would pass the inspection or be condemned as worthless.

How changed is every thing since that day. Our small grain (I wish we were raising more of it) is now taken down with the well constructed cradle, and in many sections it is taken down with horse power. Our cotton, that has done more to give employment to the world, and to regulate exchanges among the different nations of the earth, than any other product, has been so improved in its preparation, that in many instances we have been enabled to give it almost the appearance of silk. We now press it into a nice, portable square package, that is easily transported to any given point. From one to two hundred pounds is now considered a day's work for a hand to pick out. That most important implement of husbandry, the plow, has been so improved by our ingenious and enterprising mechanics, that a hand will now perform nearly double the quantity of labor in a day that was formerly done, and do it much better. I am not prepared to say when our plows will be seen to pass and repass through our fields propelled by steam; though from the rapid march of improvement, I have no reason to doubt but that the day will come when that and other improvements equally astonishing will take place. I have barely touched on the improvements that have been and are constantly in progress in agriculture and agricultural implements.

Notwithstanding the improvements that have been made, and are now making, to advance the cause of husbandry, it is true, that it is far behind all other arts and sciences: for while in this age of improvement, almost every art and science has improved with the velocity of a railroad car, agriculture has moved along at a snail's pace. The reason is apparent to every one that has taken the trouble to investigate the matter. We have been raised on a virgin soil. It has been our habit to cut down the forest, and in a few years skim off the surface, and before the trees that we had belted, to enable us to grow corn and cotton under them, were fairly dead, we have heard of some other new country that held out inducements, as we supposed; the consequence has been that we have been all the time moving from one new country to another; we have never remained long enough at any one place to make experiments in agriculture, or to become comfortable. Even in my short day, and short it is, (still I find myself, gentlemen, getting a little in the grey of the evening,) I can well remember when the Oconee river, in our sister State, Georgia, (which State has given birth to many of us,) was the western boundary. Since that day, our adopted State, Alabama, has sprung into existence, and though but little over a quarter of a century old, in point of agricultural improvement, and in the amount of agricultural productions, has already surpassed some of the other States, and in a few years will be up by the side of the most prosperous. There is no portion of the globe, whose inhabitants are more deeply interested in every thing calculated to advance the cause of agriculture, than the one we inhabit. In England one-third of its inhabitants are employed in agricultural pursuits; in France two-thirds; in Italy three-fourths; while in the U. States it appears, from the most accurate calculation that has been made, that seventy-seven out of every hundred of the population are employed in the cultivation of the soil. In our own State it has been ascertained that thirteen-fourteenths of them that labor are employed in agriculture.

Our soil and climate are surpassed by none in the world in point of fertility and mildness.—There is the greatest responsibility resting on us as farmers. It is our indispensable duty, as it should be our greatest pride, to set about an improved state of husbandry. The old skinning system of taking every thing from our kind and indulgent mother earth, while we add nothing to her in return, should be abandoned at once, while our country is new, while our soil is strong and healthy, before deep gashes are cut in her back by the washing rains. Let us adopt the old horizontal system of plowing. Before our level land is exhausted by a constant pressure of crops, and we begin to turn out field after field as worthless, let us commence the manuring system, and the more so, as we have great advantages over many other portions of country in point of manuring, on account of the extensive beds of blue marl that every where are to be found on the banks of our streams; in this way we will be enabled to make our lands produce even double the present crop, and, indeed, we may far exceed that point. It is not known by any living man what an acre of land may be made to produce by a high state of manuring and proper cultivation.

It is my impression that by a judicious system of manuring our lands, the common pine lands of this section of country can be made to produce fifty bushels of corn to the acre, and two thousand pounds of cotton, as an average crop. I am so confident of success, that I have made a commencement. During the last year I prepared some six thousand bushels of compost manure on my farm, besides our cotton seed. The compost was prepared by hauling into a lot where our cattle are constantly penned, about equal parts of marl and pine straw. After suffering it to remain some three or four months, we haul it out in January. We have the present year, by way of trial, placed it in the drills. We consider this only a commencement; for, if spared, we expect this year to make more than double the quantity of last year, for I have such confidence in the importance of manuring, that I expect to devote much of the labor of my hands to its preparation. The idea of travelling over one hundred acres of land, to gather what should be produced on twenty, is so far from that wise and judicious course of agriculture, that I hope no farmer will consent to be satisfied with it.

It is only necessary, gentlemen, to look upon the present signs of the times, to see that there is throughout our entire country, a strong disposition to improve its agriculture. There has been a greater number of meetings of the farmers within the last six months, than has taken place in six years previous. This speaks a language not to be misunderstood. Those primary meetings are the forerunners of important movements that will follow. It is what I have desired to see for the last five years—a concert of action on the part of the cultivators of the soil for its improvement. It is time, it is high time, that we go to work in good earnest. During last summer, I took a trip of three months through the States of Alabama, Tennessee, and my native State, Georgia. My object, from the day I left home until I returned, was to see the state of agriculture. I took no part in the exciting topics of the day. A great many of the farms that I passed in the different States presented any thing else but a thriving appearance. I was often reminded of a remark made by Dr. Manley, in his excellent address before the Alabama State Agricultural Convention in 1841, that many of our farms appeared to the passer by, as if a shower of houses had fallen on one day, and a shower of rails the next. It is pleasing to repeat, that we have brighter prospects in view at the present. The ball is put in motion, let us keep it rolling, and in a few years the face of the country will be changed. It is from our mother earth that we have to dig out the heavy debt we owe to England, every dollar of which let us pay, and, as farmers, present an honorable and square front to the world. But in the meantime, we should endeavor to make two ears of corn grow where one grew before. By a high state of manuring our lands, and a proper attention to all the various branches of our avocation, our harvest will be increased double. Let our State step forward and throw the weight of her influence on the side of improved husbandry. Let our legislative bodies meet but once in two years. Take the money thus saved, and employ a suitable man to make a Geological and Agricultural survey of the State; also employ a professor of Agriculture in our State College; also, let there be a model farm established, where agriculture will be taught, practically as well as scientifically. We have examples before us in several of the States. Look at the vast improvements in Agriculture in New York and South Carolina. The Legislatures of those States have done much to promote the cause of husbandry. I will give you an extract of the message of Governor Noble, of South Carolina, to the Legislature of that State in 1839:

"In giving you information of the condition of the State, (says the Governor,) I should feel that I was obnoxious to the charge of neglecting one of the most important branches of industry, were I to be silent on the subject of agriculture. This pursuit of the great mass of the people has claims upon your fostering care and attention; it is the source of our wealth and power, and furnishes the means of our commercial exchanges. Its importance seems never to have been realized by the constituted authorities of the State; it is a lamentable truth, that while other branches of industry have received an impulse by wholesome laws, the great interests of agriculture have been passed by almost with silent contempt. It is now time that the State dismiss from her councils this cold indifference, and take such action on the subject as will promote its success."

Since 1839, the State of South Carolina has, as is well known, been one of the most persevering States in urging forward the claims of agriculture. She has her State Agricultural Society, and most of the districts or counties have their County Societies.

We have examples of the high estimation in which the greatest men of America have held agriculture; for they have all been practical agriculturists, or the devoted friends of agriculture, and after serving their country in the highest stations in the gift of the people, have retired to spend the evening of their days on their farms.

Agricultural Societies, from their introduction into the United States up to the present, however, have been considered, and are now viewed, as one of the principal means of improving the agriculture of the country. This association is nothing more nor less than a set of farmers, convened together to consult as to the best means of promoting their common interest; here there is no selfish object. One farmer presents one improvement, another another, and as almost every farmer conducts his farm in many respects different from his neighbor, by each giving his mode, culture and his success in his system, we have it in our power to gather up and apply much useful information, that would otherwise be entirely lost, or be confined to one farm alone. We not only often learn much by a personal examination of each other's mode of culture, but by the system of appointing committees to look, not only into the mode of culture adopted by different farmers, but to note down and re-

port the quantity of land cultivated in the various products. Should this system become universal *throughout* the State, and the reports sent up to the State Society annually, it would enable the farmer to act in the sale of his crop with a much greater knowledge of what he was doing; there would not be this constant guessing as to the probable quantity of this or that product raised. The advantages growing out of Agricultural Societies, in giving rewards or premiums for the best domestic fabrics, have done much to promote industry, creating a laudable competition, and has often led to most valuable results.

Next to Agricultural Societies as a means of improving the husbandry of the country, the reading of agricultural papers and periodicals has done and is doing much. As an evidence of the high value set on agricultural papers by the cultivators of the soil—they are daily growing into their confidence. The prejudice heretofore existing against every thing written on the subject of agriculture, generally called book-farming, is rapidly giving way to a more enlightened view, and instead of one agricultural paper that stood up solitary and alone, twenty years past, as the friend of Agriculture, there is now over thirty of these papers published, in every section of our wide spread country, scattering light and spreading useful knowledge and information in every direction. Although General Washington lived long before an agricultural paper was thought of in America, so important did he consider the perusal of Agricultural works, that he sent to Europe and procured the publications of the best writers on agriculture, and read them with diligence and reflection, drawing from them such scientific and practical hints as he could advantageously use in improving his farm.

The improvement of mechanic arts is equally important with that of the improvement of husbandry. We are indebted to the Mechanic for our success as farmers; at every step that we take without these indispensable implements of husbandry, in daily use, by which we are enabled to cultivate the earth, what could we do? How could we succeed as farmers, without the plow, the hoe, the axe, the hundred other implements, that are indispensable to our success as farmers, that are furnished us by the industrious and ingenious Mechanic? We are indebted to the Mechanic for the houses we occupy, for the cloths we wear. Without the printing press, how would we be informed of the various improvements that are constantly going on in agriculture? What disposition would we make of our surplus products, without the aid of the Mechanic?—without the steamboat and the ship, to transport our cotton to distant lands, and furnish us with the indispensable articles in daily use? We should succeed but poorly as farmers. Hence we say that the farmer and the mechanic, are twin brothers, alike dependent on each other for support and success.

It is not at all wonderful that our Heavenly Father, should have selected a garden as the residence of the first pair. None but those who cultivate a garden can form any just idea of the pleasure it affords those who spend a portion of their time in this delightful employment. We have never yet sufficiently appreciated the comforts, to say nothing of the luxuries of a well-cultivated garden. Indeed, Horticulture is only an improved state of Agriculture. A well cultivated garden, will supply half the daily demands of a family. In our sunny South, we may be supplied with vegetables and fruits all the year round from the garden, of some kind. I know it has been common with us to turn over the garden to some extent to the ladies, and in many instances, (be it said to their honor) they manage it much better than we do; for they have that proper taste, so necessary to the management of a nice and handsome garden. And if we, in our travels through the country, would make it our business to collect wherever we go, all the rare and valuable vegetables, fruits and flowers, (yes, flowers, if you please,) and place them in the hands of our wives and daughters, they would give a good account of them. I believe there is no time so profitably spent as that devoted to the preparation and cultivation of a garden. Here, morning, noon and night, you make your application for nourishment, and if you have done your duty well, you do not apply in vain; you not only are supplied with that which is pleasant and palatable, but that which is healthy. We have said that the ladies have sometimes conducted the arrangements of the garden; and, so far as flowers are concerned, here is her appropriate home; here, surrounded by the blossoms she has cultivated with her own fair hands, she delights to dwell. It has been most appropriately remarked by some writer, that while the seeds, vegetables and fruits of the earth, are the bounties of the Almighty, that flowers are his smiles. We would recommend every farmer, and indeed every one, to cultivate a taste for Horticulture. Nothing aids so much as a well conducted garden, no matter how small it may be, to make home a pleasant and happy place. After we have toiled throughout the day, how pleasant to return in the evening, and seat ourselves under some shade tree in the garden that we have planted with our own hands. Nothing is so well calculated to soften down our nature as a stroll through a beautiful flower garden. The man who plants a fruit, or a shade tree, becomes to some extent a public benefactor.

A few of the friends of Agriculture, anxious to improve the state of husbandry in our new country, where but the other day, the red man of the forest was the only occupant, met in this town in 1839, and formed themselves into an Agricultural Society. Since the formation of an association, some of its early and most devoted friends have gone to that bourne from whence no traveller returns. Many of us yet live, and enjoy the pleasure of meeting together from time to time, to consult for the good of the whole. That our society has accomplished all that its friends hoped for, we do not pretend to claim: that it has done some good, we are equally confident. All we now want, to make the Barbour county Agricultural Society, the great centre from which shall be spread out useful and important knowledge, that will do much to improve the farming interest of this country, is a united effort, on the part of its members. The farmers of this country have it in their power, to make it one vast garden; and by a universal effort to improve the Agriculture of these United States, they can soon become the grainery of the world.

CULTIVATION OF ASPARAGUS.

Of all vegetables, treated as "*greens*," the asparagus is considered by most, as standing at the head of the list. Comparatively few, however, provide themselves properly with a supply; or even where they have had an abundance, it is not of the first quality. Perhaps a few hints on its culture, and on the mode of obtaining the finest, may be acceptable at this time.

The difference between large and small asparagus, depends very much on cultivation, a deep, rich soil, and *plenty of room between the plants*, producing the largest growth. Something also doubtless is to be attributed to the variety; as by a successive selection of seed from the thriftiest plants, an ultimate improvement may be obtained. Hence, in making a bed, seed from those plants which are known to be very large, are to be preferred. If good plants, one or two years old, can be obtained at hand, the bed will of course be accelerated one year.

A common and a good practice in preparing an asparagus bed, is to trench the ground two spades deep, and then return the earth thus removed, mixed with alternate layers of nearly an equal quantity of stable manure, until the top of the bed is six inches above the surface of the ground. But a great improvement on one part of this process is—after each layer of soil is thrown on the preceding layer of manure, to *intermix it very thoroughly* with the manure, by means of a coarse iron rake, potatoe-hook, or other suitable tool. This thorough admixture of soil and manure, though scarcely ever practised, is of the greatest importance, as large lumps of pure manure and of earth, without being finely divided and interfused, form but a poor material for the extension of the fine and delicate fibres of the growing plants.

The bed being ready for the reception of the plants from the seed bed, which should be removed with the least possible injury to the roots, proceed to lay off the trenches for the rows. One of the greatest errors with most cultivators is crowding their plants too closely together; they wish, after so much labor in the preparation of a fine bed, to obtain the largest possible supply from it, but defeat their own purpose by the slender and diminished growth resulting from such treatment. The nearest possible distance which ought ever to be admitted in an asparagus bed, is one foot apart *in* the row, and eighteen inches *between* the rows. Thus, if the trenched bed is four feet wide, only two rows can be admitted, instead of four or five, as usually practised. This may be seen by the following diagram, the dots indicating the plants,

. . . . . .
. . . . . .

which are placed, not opposite, but alternating with each other, which gives the more space between them. If there are eighteen inches of space between the rows, then there will be fifteen inches from the rows to the edge of the bed, which is none too much for the proper extension of the roots. The trenches for the plants should be made six inches deep, and wide enough to admit the roots spread out horizontally, which must be done with the fingers. The depth should be such that two or three inches of earth may be spread on the crowns of the plants. The beds may be made of any length to suit cultivators. One a hundred and fifty feet long and four feet wide will supply an abundance for a moderate sized family.

After a bed is transplanted, it should remain uncut for two seasons. Cutting sooner will greatly injure its subsequent thriftiness.

If it is remembered that the two chief requisites for success, are *plenty of room* for the growth of the plants, and a *deep, fertile soil*, no one need be at a loss in the cultivation of this fine vegetable. Good, constant, and cleanly culture, as every one must know, is indispensable. These requisites are of vastly greater consequence than large varieties merely. Indeed, the fact that with good cultivation and management, no plants are small, and without that none are large, has led many intelligent persons to suppose that the difference between giant and small varieties is owing entirely to these circumstances, and they are not far wrong.

One advantage which may be derived, from planting the rows more distant than is usual, besides large growth, is the facility of keeping the ground cultivated, a light plow drawn by one horse being passed freely between them.

With such distances, and the facilities afforded for horse cultivation, much finer plants may be had from a rich, deeply plowed soil only, than without them from a trenched bed two feet deep, though depth and distance combined are the best.—*Albany Cultivator.*

From the Maine Farmer.

Asparagus is now extensively cultivated in the Middle and Northern States, and is generally much admired as an esculent. But owing to some imperfection in its management, it is seldom presented in our markets in that degree of perfection of which it is susceptible. In the country, it is almost invariably small, hard and tough, presenting but few attractions either to the eye or palate. As we have been requested to publish an article, relative to the cultivation of this vegetable, we present the following from the Southern Agriculturalist, detailing the *modus operandi* pursued in Spain, and which we believe is in most respects strictly coincident with the practice usually pursued by experienced gardeners and horticulturalists in our own country.

Asparagus is a plant found naturally on the beach of various parts of the coast of Europe, where it is covered by the drifting sand, and watered by salt water on high tides. Sand and salt water occasionally may, therefore, be regarded as indispensable conditions for maintaining it in health. How seldom is this thought of! It, however, explains in part, the excellence of St. Sebastian asparagus.

It seems that at the mouth of the Urumea is a narrow strip of land, about three feet above high-water mark, consisting of alluvial soil and the wearing away of sand-stone hills, at whose foot

it is placed. This is the asparagus ground of St. Sebastian. Beds are formed five feet wide, without any previous preparation except digging and raking. In March the seed is sown in two drills, about two inches deep, and eighteen inches from the alleys, thus leaving a space of two feet between the drills. The rows run invariably east and west—doubtless in order that the plants may shade the ground during the heats of summer. When the seedlings are about six inches high, they are thinned to something more than a foot apart. Water is conducted once a day among the alleys and over the beds, so as to give the seedling an abundant and constant supply of fluid during the season of their growth. This is the cultivation during the first year.

The second year, in the month of March, the beds are covered with three or four inches of fresh night soil from the reservoirs of the town; it remains on them during the succeeding autumn; the operation of irrigation being continued as during the first season. This excessive stimulous, and the abundant room the plants have to grow in, must necessarily make them extremely vigorous, and prepare them for the production of gigantic sprouts.

In the spring, the asparagus is fit to cut. Doubtless all its energies are developed by the digging in of the manure in the autumn of the second year; and when it does begin to sprout, it finds its roots in contact with a soil of inexhaustible fertility. Previously, however, to the cutting, each bed is covered in the course of March very lightly with dead leaves, to the depth of about eight inches; and the cutting does not commence till the plant peeps through this covering, when it is carefully removed from the stems, in order that the finest only may be cut, which are rendered white by their leafy covering, and succulent by the excessive richness of the soil.

In the autumn of the third year, after the first cutting, the leaves are removed, and the beds again dressed with fresh night-soil as before; and these operations are repeated year after year. In addition to this, the beds are half under salt water annually at spring tides.

Let any one compare the mode of culture with ours, and there will be no room for wondering at the difference in the result. The Spaniards use a light, sandy soil; we are content with anything short of clay. They irrigate; we trust to our rainy climate.

Some years since, we had a bed of Asparagus which from some unknown and inscrutable cause, suddenly ceased growing; the spires no sooner attained a certain height, than, like the fabled trees around the tomb of Protesalaus, they withered and died away. We manured and watered, but all to no purpose, and we at last gave up all idea of renovating the plants, in despair. In digging about the roots, we found that they had been lacerated and almost wholly consumed by worms, a few of which were still at their work on the tubers. They were cornworms, or bore so near a resemblance to them that it would have been difficult to distinguish them apart. Influenced by the presumption that the roots were hopelessly injured, we determined to apply salt to the bed in order to test its efficacy both on the asparagus, and in destroying the worms. We accordingly applied half a peck, and to our surprise the asparagus started almost immediately, and in a short time acquired a degree of vigor and luxuriance surpassing even its former growth. Since then we have used salt as an ordinary manure for this root, and our experience has proved conclusively to our own mind that it is decidedly the best and most efficacious stimulant that can be applied.

A correspondent says, "I have an asparagus bed, 30 feet by 5 feet, on which I put one hundred weight of salt, about the middle of March, last year, and also this year. The increase of crop, both with regard to size and number, is most extraordinary." In another place, a case is given where too heavy and often repeated dressings of salt destroyed the asparagus, though the precise amount of this over-dose is not given.

HORTICULTURAL OUTLINE.

AN OUTLINE of the first principles of HORTICULTURE. by JOHN LINDLEY, F R. S. &c. &c., Professor of Botany in the University of London, and assistant Secretary of the Horticultural Society.—[CONTINUED.]

VIII. FRUIT.

209. Fruit, strickly speaking, is the pistillum arrived at maturity.

210. When the calyx adheres to the pistillum, and grows with it to maturity, the fruit is called *inferior;* as the Apple.

211. But when the pistillum alone ripens, there being no adhesion to it on the part of the calyx, the fruit is called *superior;* as the Peach.

212. The fruit is, therefore, in common language, the flower, or some part of it, arrived at its most complete state of existence; and, consequently, is itself a portion of the stunted branch. (153.)

213. The nature of its connection with the stem is therefore the same as that of the branches with each other, or leaves with their stem.

214. A superior fruit, consisting only of one, or of a small number of metamorphosed leaves, it has little or no power of forming a communication with the earth and of feeding itself, as real branches have. (89.)

215. It has also very little adhesion to its branch; so that but slight causes are sufficient to detach it from the plant, especially at an early age, when all its parts are tender.

216. Hence the difficulty of causing peaches and the like to *stone*, or to pass over that age, in which the vascular bundles that join them to the branch become woody, and secure them to their place.

217. For the same reason they are fed almost entirely by other parts, upon secreted matter which they attract to themselves, elaborate, and store up in the cavities of their tissue.

218. The office of feeding such fruit is performed by young branches which transmit nutriment to it through the bark. (69.)

219. But as young branches can only transmit nutriment downwards, it follows that unless a fruit is formed on a part of a branch below a leaf-bud, it must perish,

220. Unless there is some active vegetation in the stem above the branch on which it grows; when it may possibly live and feed upon secretions attracted by it from the main stem.

221. But inferior fruit, consisting at least of the calyx in addition to the pistillum, has a much more powerful communication with the branch; each division of its calyx having *at least* one bundle of vascular and fibrous tissue, passing from it into the branch, and acting as a stay upon the centre to prevent its breaking off.

222. Such fruit may be supposed much more capable of establishing a means of attracting secretions from a distance; and consequently, is less liable to perish from want of a supply of food.

223. It is therefore not so important that an inferior fruit should be furnished with growing branches above it.

224. Fruit is exclusively fed by the secretions prepared for it by other parts; it is therefore affected by nearly the same circumstances as flowers.

225. It will be large in proportion to the quantity of food the stem can supply to it; and small in proportion to the inability of the stem to nourish it.

226. For this reason, when trees are weak they should be allowed to bear very little, if any fruit; because a crop of fruit can only tend to increase their debility.

227. And in all cases each fruit should be so far separated from all others as not to be robbed of its food by those in its vicinity.

228. We find that nature has herself in some measure provided against injury to plants by excessive fecundity, in giving them a power of throwing off flowers, the fruit of which cannot be supported.

229. The flavor of fruit depends upon the existence of certain secretions, especially of acid and sugar; flavor will, consequently, be regulated by the circumstances under which fruit is ripened.

230. The ripening of fruit is the conversion of acid and other substances into sugar.

231. As the latter substance cannot be obtained at all in the dark, is less abundant in fruit ripened in diffused light, and most abundant in fruit exposed to the direct rays of the sun, the conversion of matter into sugar occurs under the same circumstances as the decomposition of carbonic acid. (141 and 279.)

232. Therefore, if fruit be produced in situations much exposed to the sun, its sweetness will be augmented.

233. And in proportion as it is deprived of the sun's direct rays that quality will diminish.

234. So that a fruit which when exposed to the sun is sweet, when grown where no direct light will reach it, will be acid; as Pears, cherries, &c.

235. Hence acidity may be corrected by exposure to light; and excessive sweetness, or insipidity, by removal from light.

236. It is the property of succulent fruits which are acid when wild, to acquire sweetness when cultivated, losing a part of their acid.

237. This probably arises from the augmentation of the cellular tissue, which possibly has a greater power than woody vascular tissue of assisting in the formation of sugar.

238. As a certain quantity of acid is essential to render fruit agreeable to the palate, and as it is the property of cultivated fruits to add to their saccharine matter, but not to form more acid than when wild, it follows that in selecting wild fruits for domestication, those which are acid should be preferred, and those which are sweet or insipid rejected;

239. Unless recourse is had to hybridism; when a wild insipid fruit may be possibly improved, (204,) or may be the means of improving something else.

240. It is very much upon such considerations as the foregoing that the rules of training must depend.

IX. SEED.

241. The seed is the ovulum arrived at perfection.

242. It consists of an integument enclosing an *embryo* which is the rudiment of a future plant.

243. The seed is nourished by the same means as the fruit; and, like it, will be more or less perfectly formed, according to the abundance of its nutriment.

244. The plant developed from the embryo in the seed, will be in all essential particulars like its parent species;

245. Unless its nature has been changed by hybridising. (204.)

246. But although it will certainly, under ordinary circumstances, reproduce its species, it will by no means uniformly reproduce the particular variety by which it was borne.

247. So that seeds are not the proper means of propagating varieties.

248. Nevertheless, in annual or biennial plants, no means can be employed for propagating a variety, except the seeds; and yet the variety is preserved.

249. This is accomplished solely by the great care of the cultivator, and happens thus.

250. Although a seed will not absolutely propagate the individual, yet as a seed will partake more of the nature of its actual parent than of any thing else, its progeny may be expected, as really happens, to resemble the variety from which it sprung, more than any other variety of its species.

251. Provided its purity have not been contaminated by the intermixture of other varieties.

252. By a careful eradication of all the varieties from the neighborhood of that from which seed is to be saved, by taking care that none but the most genuine forms of a variety are preserved, as seed-plants: and by compelling by transplantation a plant to expend all its accumulated sap in the nourishment of its seeds, instead of in the superabundant production of foliage, a crop of seed may be procured, the plants produced by which will, in great measure, have the peculiar properties of the parent variety.

253. By a series of progressive seed-savings upon the same plant, plants will be at length obtained, in which the habits of the individual have become as it were fixed, and capable of such exact re-production by seed, as to form an exception to the general rule; as in turnips, radishes, &c.

254. But if the least neglect occurs, in taking the necessary precautions (252,) to insure a uniform crop of seed, possessing the new fixed properties, the race becomes deteriorated, in proportion to the want of care that has occurred, and loses its characters of individuality.

255. In all varieties those seeds may be expected to preserve their individual characters most distinctly which have been the best nourished, (243;) it is consequently, those which should be selected in preference for raising new plants from which seed is to be saved.

256. When seeds are first ripened, their embryo is a mass of cellular substance, containing starch, fixed carbon, or other solid matter; and in this state it will remain until fitting circumstances occur to call it into active life.

257. These fitting circumstances are, a temperature above 32 degrees Fahr., a moist medium, darkness, and exposure to air.

258. It then absorbs the moisture of the medium in which it lies, inhales oxygen (278,) and undergoes certain chemical changes; its vital powers cause it to ascend by one extremity for the purpose of finding light and decomposing its carbonic acid (279,) by parting with its accumulated oxygen, and to descend by the other extremity for the purpose of finding a constant supply of crude nutriment.

259. Unless these conditions are maintained, seeds cannot germinate; and, consequently an exposure to light is fatal to their embryo, because (278) oxygen will not be absorbed in sufficient quantity to stimulate the vital powers of the embryo into action, for the purpose of parting with it again, by the decomposition of the carbonic acid that has been formed during its accumulation. *(To be continued.)*

Artificial Manures.

From the Albany Cultivator.

The preparation and use of manures constitute one of the points in which the advance of modern agriculture is most apparent. For this advance, we are indebted to the application of chemical science to an investigation of the substances most commonly used to promote the growth of plants. An imitation of the operations of nature has thus been effected, in which there has been a decided improvement on the original, as the change necessary to convert organic matter into the fertilizing material is effected in a very short time; the bulk diminished while the efficiency is increased; and the disgusting offensive character beloging to some of the original compounds entirely done away. Substances, too, once wasted, or rather considered of no value, are now in the course of a few weeks converted into manures of the first quality. Every discovery of this kind is of importance to the agriculturist; for although some of them, it is probable, will not be made useful on a large scale, and some of the preparations cannot become common in this country; still there are many which we are confident will be extensively used everywhere; and the better they are known, the more highly appreciated by the farmer or gardner.

Poudrette, or prepared night soil, is one of the most valuable of these prepared manures, concentrating in a great degree the elements of fertility; and as prepared, being easily portable, used with facility, perfectly inoffensive, and very powerful in its action. The demand for this article is constantly increasing, and the proofs of the value of the manure rapidly accumulating. The value of poudrette, compared with good stable or barn yard manure, is estimated as one of the former to from 12 to 15 of the latter; and some have even estimated the difference as still greater. When we remember that this manufacture is designed to convert what has always been a nuisance and source of multiplied diseases in our cities, into a means of fertility and wealth, its importance will be duly estimated.

Another preparation, which is receiving some favor, is that produced by Bommer's patent, in which all ligneous or woody plants, such as straw, cornstalks, weeds, roots, sea-grass, and in fact all vegetable matters, are converted into manure in a much shorter period than by the usual course of decomposition. It is pronounced, as efficient as stable manure, more lasting, and costing but little. The process of preparing this manure has nothing difficult about it. It is probable the patent, for a time, even were its value unquestioned, prevents the extensive use which this mode of preparing vegetable matter might otherwise have obtained. Of the peculiar forms of the process we know nothing; but the testimony in its favor from those who have tried it, appears ample. Patent manures, patent implements, and patent medicines, are very apt, however, by practical farmers, to be placed in the same category.

The English agricultural journals have within the past year frequently alluded to the qualities of a new fertilizing preparation called Daniel's Patent Manure. The specifications of the patent have been received in this country; and though evidently intended to mystify, rather than disclose, the real process of making the manure, it is easy to see that a powerful manure must be the result of the combination. According to the specification, the materials of the manure are divided into three classes.—First: ligneous matters, peat, straw, weeds, &c. Second: bituminous matters; such as mineral coal, (bituminous doubtless) asphaltum, pitch made from coal tar, or other pitch, mineral resin, and also tar. Third: animal matter; such as butcher's offal, graves, flesh of dead animals, also fish.

The ligneous matters are reduced to powder by grinding, or by the action of caustic lime. The bituminous matters are also ground into powder; if sticky like pitch, a small quantity of dry quick lime is added to prevent adhesion to the machine; if liquid, they are converted into vapor by dry distillation, in which vapor the ligneous materials are saturated; or if preferred, the soft bituminous matters are dissolved in water, to which caustic alkali has been added, and in this the ligneous matters are steeped.—The animal matters are mixed with the ligneous and bituminous ones, and then the whole reduced to a powder.

Such a preparation cannot fail to be a fertilizer of the most powerful kind, though it is evident the process needs much simplification before it can be adapted to the use of farmers generally.

Guano is probably the most powerful natural manure known; and the artificial one that shall most nearly resemble that, will doubtless be the most valuable. Voelckel's analysis, the latest and best of this substance, as given by Dr. Dana in his Muck Manual, shows that it contains in the various salts of ammonia 32 parts in 100, sulphates of potash and soda 9 parts, phosphate of lime 14 parts, soluble geine or humus 12 parts, and insoluble undetermined organic matter 20 parts. The artificial manures are valuable in proportion as they furnish the materials for the ammonia, phosphates, and sulphates, which abound in guano. It is likely, indeed certain, that the immense masses of guano existing on the islands of the Pacific, are in a very different chemical condition from what they were when first deposited by the sea fowl that frequent those coasts and islands; consequently in no fresh manures in any country, can we expect to find the same combination of fertilizing substances as in guano. In no other country could such masses have remained without the wasting or dissipation of their most valuable parts, or their entire substance; the nearly total absence of rain in the guano region, preventing such a result. The guano is, therefore, not only the result of the accumulation, but the chemical combination of ages, and what agriculture requires of science, is the discovery of the means of effecting in a short time what nature has been centuries performing.

In all preparations of artificial manures, two conditions are requisite; first, value as a fertilizer; and second, facility and simplicity of preparation. With the first, the labor of manufacture is lost; without the second, few farmers will be able to avail themselves of the benefits such manures offer. Thus far, we are inclined to the belief, that of all the artificial manues, poudrette best fulfils these two conditions; but it by no means follows that other combinations may not be discovered, equally simple, and more powerful. Of one thing we may be assured; all such preparations, when brought within his reach and his means, will be hailed by the farmer with pleasure.

Time is Money.

From the Union Agriculturist.

Dear Sir:—I begin to fear that yourself and others may think that I do nothing but write; as I send you something for every number of your paper. Well, suppose that should be the conclusion,—if I had nothing else to do all would be well. But farmers have something to do, besides writing for agricultural papers.—This all know; how then, many will inquire, does C. find time to write. If I may answer the question myself, I shall say, that I am troubled to dispose of my spare time—of the long winter evenings—of the stormy days, and a great many bits and ends of time.

I may be answered—teach your children; make and mend such articles as you can that you need; read the newspapers, and such books as you have or can get. This I do, and yet there is spare time.

My wife and self manage to teach seven children; and during the winter, keep them at their studies more hours than if they were at school. I make and repair all the wood part of my tools, and some of the iron, and repair all our boots and shoes; my wife and daughters, the oldest sixteen, work up our wool, about 70 pounds, both spin and weave it; myself and boy, thirteen years old, till about forty acres, and provide for stock that require 40 tons of hay, besides all the coarse fodder that we can muster; this, besides all the incidental work about the house and farm, we do without hiring.—Books and papers are literally worn out by being read. The Chicago Democrat or Union Agriculturist, is hailed with as much joy as an old friend; and if, as we frequently do, we receive a paper from distant friends, nothing could give greater pleasure, except the appearance of those friends.

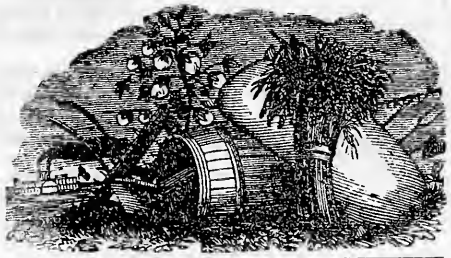
A great wonder with me is, how men and families spend their time, without even a paper or a book, or any thing else of the kind. Even their Bible might as well be made of wood, bound and gilt, to save appearances, as to be filled with the words of God.

Never have I written, except in the evening; and then generally have some half dozen children about the same time at their studies.—Some with slates, some with books, and some with more mischief than study. Even now, one little one pops up her head, with, "Father, how much is eleven times six?" "Set down eleven and multiply it by six." "What, six times eleven?" "No, six times one, and then six times one again." "O! I see; sixty-six." "Now multiply 7, 8 and 9 in the same way?" So I write, teach and rest myself; at the same time killing *three* birds with one stone.

Now to my reasons for writing. If I say I write to benefit others, none will believe me in these selfish times; well then, I write to amuse myself, and to use time. A. CHURCHILL.

Avon, March, 1841.

A correspondent of the Charleston Evening Post mentions a rattlesnake that was found dead in the woods, near Georgetown, South Carolina, which was 7 feet long, had 73 rattles, and teeth an inch and a half long.



The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 7.....JULY, 1845.

Articles intended for publication in the SOUTHERN CULTIVATOR (except advertisements) must be in the hands of the Editor at Athens by 12 o'clock of the 20th of the month; otherwise they cannot be inserted in the number published on the first of the month next thereafter.

Many postmasters continue to send money for subscriptions to the editor at Athens. They are particularly requested to address, hereafter, all letters relating to subscriptions to the publishers at Augusta.

The reader's attention is particularly directed to the Report, published in this number, of the Committee on Farms of the Agricultural Society of Pendleton District, S. C. The whole report will be found very interesting; and more especially that part of it which describes the farm and extraordinary management of the Hon. John C. Calhoun.

☞ The reader will, we hope, have detected and corrected for himself, in the ninth line of the editorial article on feeding plants, in our last number, the unfortunate error by which the word *grapes* was put for *grasses*.

Products of Southern Industry.

Somebody has written, that "mankind might do without physicians, if they would observe the laws of health; without lawyers, if they would keep their tempers; without soldiers, if they would observe the laws of peace; and without preachers, if each one would take care of his own conscience;---but there is no doing without farmers."

If this be true as regards farmers, how much stronger the case is as regards the planters of the South, must be manifest on an examination of the following table. How would the United States get along without the 50 or 60 millions of wealth brought into the country every year by our cotton crop? What would become of the millions of people in other parts of the United States who live chiefly by means of this wealth? Is it at all surprising that the people of other States, who, by means of their own resources, can hardly keep soul and body together, seeing what the annual income of the South is, should strive so diligently to get their hands into our pockets? But it is surprising---it does move our especial wonder---that our people should, so patiently, and for so long a time, have submitted to a system of pillage according to law, and of waste from their own folly and bad management, that has made the South one wide scene of desolation, compared with the appearance of things among our neighbors who are living mainly on the fruits of our industry.

When will the South awake to a proper sense of its own true interest, and of the importance of its industry not only to the rest of the United States, but to the whole civilized world. Just look at this table, made out by the National Intelligencer from the public records, for the year ending 30th June, 1844.

TABLE

Showing the export of leading articles of domestic produce, for the year ending the 30th June, 1844. According to the table, the amount exported of each article was as follows:

Cotton	$54,063,501
Tobacco	8,397,282
Rice	2,182,468
Bread stuffs	9,056,960
Beef, Pork, &c	6,149,379
Products of the sea	3,350,501
Products of the forrest	5,908,712
Manufactures of cotton	2,898,780
Other manufactures	5,080,854
All otker articles	2,726,760
Total amount of exports was	$99,715,197

We say again, examine this table carefully, and compare the exports of Southern agricultural products with the exports of all other articles of every sort put together.

Total exports, near	$100,000,000
Cotton alone, more than half the whole, over	54,000,000
Cotton and Rice, over	56,000,000
Cotton, Rice and Tobacco, over	64,000,000
All other exports, less than	36,000,000

With such an income annually, what ought not the South to be---and what is its condition? Let every one who has any hand in the creation of this vast amount of wealth, look around him, and ask himself what has become of it. Then let him, with firm resolve, set about correcting, as far as he can, the existing state of things, by supplying his wants, as far as possible, from his own plantation; buying, if he must buy, nothing that he can do without, of either food, clothing, implements or luxuries, that is not the product of Southern labor; and, above all, repressing in himself, and discountenancing in others, that spirit of absenteeism, that has wrought us, perhaps, as much mischief as any other single folly we have indulged ourselves in.

Southern Folly.

Our Southern people are, beyond all question, the slowest to learn wisdom of any people on this earth. Here we are with an impoverished soil, a staple to the cultivation of which all our energies have been devoted in times past, now reduced to a price in the market that barely remunerates the planter for his outlay of capital and labor---if, indeed, it does that; pressed down and plundered and spurned by an unprincipled combination, who contrive, by iniquitous laws, that we shall eat only such part of the fruits of our own labor as they choose to allow; and surrounded by enemies who are both openly and in secret striking at the very existence of our institutions, and of our property; and yet we coolly and calmly and inconsiderately indulge in our old habits of profusion and extravagance, formed when cotton bore a good price, and money was abundant; when the Constitution afforded us protection from plunder, and our institutions were not meddled with. Read the following extract from an account, by the New York Herald, of the late race on Long Island between Peytona and Fashion, and the conclusion is irresistible that the people of the South have yet to suffer more severely before they come to their senses. It is too bad to have it said of us, sneeringly and contemptuously, "how freely the South will spend its winnings---Peytona didn't fly round the Union course so fast as her liberal supporters will dash through their tens and their fifties, 'till they reach the last dollar." "The Southern men will spend their last cent here." Surely men who will act so as to expose themselves to such remarks---who will act in a manner so utterly ruinous to the part of the country in which they live, and in which they expect to die --squandering their money among a people who, when all is spent, regard them with supreme contempt, who have not one single feeling of sympathy with us of the South. Surely men who act thus ought to suffer.

From the New York Herald.

And has not the North been well licked? Half a million of dollars has been lost. That's the way to reach the tender sensibilities of the Northern men. As

The touched needle trembles to the pole,

so do their souls forever turn to that great nervous centre of sentiment and feeling---the pocket. That is the only accessible avenue to their humanity, and into that the South has now "walked" with a vengeance. Half a million of dollars! How the poor creatures bleed! The shock vibrates in every nerve. It will take years of thimble-rigging to make up the loss to many of our respectable, honorable, liberal, upright, loafing Northern "jockeys." And then, how freely the South will spend its winnings! Peytona didn't fly round the Union Course so fast as her liberal supporters will dash through their "tens" and "fifties," till they reach the last dollar. The hotel-keepers---the *cabaretiers* ---the professors of the *bille*---and all the practical philosophers who kindly reduce the plethora of the votaries of pleasure and "the turf," are felicitating themselves on the victory of the South. The Southern men, say they, will spend their last cent here; whilst the Northern and Eastern men, if they had won, would have buttoned up their pockets and "mizzled."

Kenilworth Pigs.

The American Agriculturist, speaking of the pigs purchased of R. L. Allen, of Buffalo, by David Bryan, of Bellevue, Talbot county, Georgia, says they are of "the largest and finest white breed to be found in England. Two sows of this lot were judged to weigh over 500 lbs., in good breeding condition, and may be fattened to weigh 700 lbs. The yearling boar was large and fine and would weigh about 400 lbs. There were some younger ones in the lot quite as promising. These animals were ordered by Mr. Bryan, for the purpose of meeting the taste of those planters who wish more size than is generally found in the other good breeds. We are confident they will be satisfied in this respect, and get their pork with a reasonable amount of feed, which is seldom the case with overgrown animals. We are glad to notice these improvements going forward at the South. We can confidently recommend the importation of Mr. Bryan to his neighbors in Georgia."

Oatmeal as Human Food.

The American Agriculturist, in the number for March, spoke in commendation of the value of oatmeal as food for man. Thereupon also Blackwood's Magazine holds forth in the following lofty style in praise of Scotland's favorite oat-cakes and porridge, bannocks and brose:

"You won't pity us Scotch oatmeal eaters any more, Mr. Cockney, we guess. Experi-

ence and science are both on our side. What makes your race horses the best in the world, may be expected to make your peasantry so too. We offer you, therefore, a fair bet. You shall take ten English plowmen, and feed them upon two pounds and a half of wheaten flour a day, and we shall take as many Scotch plowmen, and feed them upon the same weight of oatmeal a day---if they can eat so much, for that is doubtful---and we shall back our men against yours for any sum you like. They shall walk, run, work or fight you, if you like it, and they shall *thrash* you to your heart's content. We should like to convince you that Scotch porridge has some real *solid* metal in it. We back the oat cake and the porridge against all the wheaten messes in the world. We defy your home made bread, your baker's bread, you household bread, your leaven bread, and your brown Georgies---your fancy bread and your raisin bread---your baps, rolls, scones, muffins, crumpets and cookies---your bricks, biscuits, bakes, and rusks---your Bath buns, and your Sally luns---your tea cakes, and saffron cakes, and slim cakes, and plank cakes, and pan cakes, and soda cakes, and currant cakes, and sponge cakes, and seed cakes, and girdle cakes, and singing hinnies---your short bread and your currant buns---and if there be any other names by which you designate your wheaten abominations, we defy and detest them all. We swear by the oat cake and the porridge, the substantial bannock and the brose---long may Scotland produce them, and Scotchmen live and fight upon them!"

Sheep.

We have thrown together below several extracts from other papers, on the subject of sheep raising and wool, as a new business for the South.

From the South Carolinian of May 15.

THE CAROLINA MOUNTAINS FOR SHEEP WALKS.—There is not in the world a finer country for sheep husbandry than the mountainous regions of South Carolina. If a few of our enterprising landholders, who are largely interested in those high-lands, would unite in some plan of operations for inducing the settlement of respectable emigrants from Europe or the Northern States—emigrants familiar with the grazing business, and wool growing—our mountain regions would soon present returns scarcely inferior in value to the products of the lands in the best agricultural sections of the State. The entire Districts of Spartanburg, Greenville, Pickens, Anderson, with portions of Laurens, Union and York, would afford room for many millions of sheep.

Sheep husbandry is rendered profitable with land valued at thirty dollars an acre in the hard climate of Vermont, also in Spain, Germany and England, in which countries land cannot be bought at any price; and with these examples before us, why should we longer neglect to improve the resources within our reach? Let us hope that a few of our enterprising landholders will unite their efforts and go ahead resolutely in this good work. We think we could refer them to persons who could devise a plan of operations that could not fail to prove largely beneficial to all concerned.

From the South Carolinian of May 22.

FINE FLOCKS OF SHEEP IN THE VICINITY OF COLUMBIA, S. C.—The practical agriculturist and genuine lover of rural affairs, would be both gratified and amply repaid by visiting the magnificent flocks of sheep belonging to Col. Wade Hampton and Mr. B. F. Taylor, in the neighborhood of this city. Those who wish to be convinced of the fact that we can successfully raise fine sheep in our Southern climate, should go by all means. Examples like these are worth more than a heaped up mountain of arguments, theoretically prepared by those who take interest in advocating such things through the medium of the agricultural journals. The flock of Col. Hampton is superior to any other we have ever seen in any part of the U. States. They are pure blooded Liecesters, and Bakewell himself were he living, would be proud to own them. They cannot have lost much, if anything, of their characteristic superiority, if we judge by some of his animals which have matured. Mr. Taylor's flock is chiefly Merino with a dash of the blood of the African or Broad-tailed sheep, and they have shown themselves to be extremely fine and prolific. He recently showed us the fleece of a buck lamb 14 months old, which weighed 10½ pounds. Dr. Parker, the Superintendant of the Lunatic Asylum in this city, has just shorn a pair of last spring's Liecester lambs, about 14 months old, bred by Col. Hampton, and the weight of the fleece from the buck lamb was 13½ pounds whilst that from the ewe lamb weighed 11½ pounds.

Col. Hampton has shorn all his lambs of the present season, and we will make the wool growers of the North open their eyes, when we state that the average weight of the fleece of about sixty head, was four pounds each. He has done this in order to relieve them from the oppressive heat of summer.

On visiting his flock a few days since, we found them in fine condition, without the least appearance of disease of any kind amongst them, and what is remarkable, they have kept in good order on very short pasturage, which is one of the best evidences we can give of the thrift of this remarkable breed of sheep.

With such flattering results before us, why should we despair of making a great portion of our State profitable in this branch of rural enterprise. We have already adverted to the superior advantages of our mountain regions as sheep walks, and we shall on some other occasion gather information and give our own views upon the propriety of introducing good breeds of sheep in the middle sections and lower-country of South Carolina. That the whole sand-hill region bordering on our extensive swamps is eminently adapted to this business, has been fully proven by the success of the flocks above mentioned.

We should like to see such flocks obtain throughout the State, and we fancy the gentlemen above named would do all in their power to gratify such individuals as might desire to make the experiment, by furnishing them superior stock animals, at a moderate rate, when their prices are compared with the heavy and hazardous expenses of importing them immediately from England or the North.

John Randolph said he would walk a hundred yards out of his way merely to kick a sheep. We would go a journey of fifty miles to admire a good flock. He might have been wise in his aversion to these animals. We know we are wiser in our great fancy for them.

After reading these extracts, consider what Mr. Buckley of Yates county, N. Y., says on the same subject in a letter to the editor of the Albany Cultivator.

"I cannot help thinking that the middle and eastern portion of Tennessee, the western part of North Carolina, and northern part of Georgia, has greater natural advantages for the raising of sheep than any other portion of the U. States. I spent the summer season exploring the mountains of those State, and may give you some further account of them in future letters."

Then we have a letter from Mr. Skinner to Mr. Clingman, of the Buncombe district, N. C., in which he says:

"Well, I am happy to add that two enterprising and most meritorious citizens of your State have agreed to take measures for the importation of the Alpaca sheep into the mountains of North Carolina."

In Tennessee they are actively engaged in increasing their stock of sheep. Indeed, every where they are going ahead of us in Georgia, in efforts to rescue themselves from the embarrassments produced by the state of the cotton markets. When will our people be aroused to a proper sense of their own interest!

In this connection we cannot omit to call the reader's attention to one of the difficulties attendant on raising sheep—and no trifling one it is.

From the Frankfort (Ky) Commonwealth.

DOGS AND SHEEP.—A few nights ago, we learn sixty-three choice ewes, selected for breeders on account of the fineness of their wool, owned by our friend Capt. John A. Holton, of Franklin county, were killed by dogs.

The destruction of sheep by dogs has long been a sore evil to the farmers of Kentucky. From the best information we have—and we have devoted much inquiry to the point—we calculate that there are annually about 10,000 sheep destroyed by dogs in the State of Kentucky. The destruction of 100 sheep in each county would give this grevious total. We know one excellent farmer, in another county, who alone has lost 600 sheep in years past, killed by dogs.

The absolute loss of the value of the sheep actually killed by dogs, is not the most serious consideration growing out of the evil. Twenty or thirty or fifty thousand dollars loss per annum distributed amongst the farmers of the State, though inconvenient portions of the loss sometimes fall upon individuals, would not be utterly intolerable: especially under the consolatory remembrance that while one loses his mutton and wool, the dogs of others, who are fond of dogs, have abundance of delicate food.—But the evil stops not here. Hundreds and thousands of farmers, owing to the terrific destruction of sheep by dogs, are utterly deterred from engaging in sheep husbandry, for which the great abundance of hill lands, now lying unproductive, are admirably adapted.

We have not a doubt that, if the ravages by dogs could be stopped, in five years from this day, two millions of dollars worth of wool, grown on lands now entirely unproductive, would be produced in Kentucky; and the amount would be gradually and indefinitely increased.

By our laws $8 are paid for every wolf killed in the State. This is designed for the protection of sheep; and in that view, we approve the policy. But at the same time, we doubt whether in any one of the last five years more sheep have been destroyed in the whole State by wolves, than were killed a few nights ago by dogs on the farm of Capt. Holton.

The disinclination of the Kentucky Legislature to adopt just measures to stop the ravages of dogs, has ever been an inexplicable puzzle to us. We have always regarded some provision on this subject as demanded no less by the public will than by considerations of policy and justice, looking to public and private interests.

The address delivered by Col. A. McDonald, of Eufaula, Ala., before the Agricultural Society of Barbour County, will be found in the columns of to-day's paper. By a perusal of which, much information will be received of interest to the agricultural portion of our community and others.

Col. McDonald is not only a theoretical planter, but adopts the best and most approved system of planting, and never fails to receive a greater remuneration for his labor than any other planter in this section of country. He has done much for the interest of the Southern planter.

We visited, by invitation, the Colonel's garden, a few evenings since, where we found a fine vegetable garden, filled with all the vegetables of the season, in great perfection. His flower garden was arranged beautifully with shrubs and flowers, which no doubt, from appearances, has had much time bestowed upon it.

His selection of fruit trees and varieties of grape, are not equalled in this section of country. We saw growing luxuriantly, the madder, and from the appearance of the young plant, we do not doubt but it can be raised successfully in this climate.—*Eufaula Shield.*

An English Farmer's Wife.

Here is a beautiful chapter from the third part of Colman's European Agriculture. Every reader may profit largely by the lesson it contains. Those who know the writer, and who have seen something of English rural life, have seen enough to convince them that, though called, even by the author, a pencil sketch, the picture is by no means overdrawn.

PENCIL SKETCH OF AN ENGLISH FARMER'S WIFE.—*By Henry Colman.*—I must claim the indulgence of my readers, if I give them an account of a visit in the country, so instructive, so bright, so cheerful, that nothing but the absolute breaking-up of the mind can ever obliterate its record, or dispel the bright vision from my imagination. I know my fair readers—for with some such I am assured my humble reports are kindly honored—will feel an interest in it; and if I have any unfair readers, I beg them at once to turn over the page. But mind, I shall utter no name, and point to no place; and if I did not know that the example was not altogether singular, and therefore would not be detected, I should not relate it. I know very well, as soon as I return to my native land, if Heaven has that happiness yet in store for me, a dozen of my charming friends—God bless them!—with their bright eyes, and their gentle entreaties, will be pressing me for a disclosure; but I tell them beforehand, I am panoplied in a stern philosophy, and shall remain immovable.

I had no sooner, then, entered the house where my visit had been expected, than I was met with an unaffected cordiality which at once made me at home. In the midst of gilded halls and hosts of liveried servants, of dazzling lamps and glittering mirrors, redoubling the highest triumphs of art and taste; in the midst of books, and statues, and pictures, and all the elegancies and refinements of luxury; in the midst of titles, and dignities, and ranks, allied to regal grandeur—there was an object which transcended and eclipsed them all, and showed how much the nobility of character excels the nobility of rank, the beauty of refined and simple manners all the adornments of art, and the scintillations of the soul, beaming from the eyes, the purest gems that ever glittered in a princely diadem. In person, in education, and improvement, in quickness of perception, and facility and elegance of expression, in accomplishments and taste, in a frankness and gentleness of manners tempered by a modesty which courted confidence and inspired respect, and in a high moral tone and sentiment, which, like a bright halo, seemed to encircle the whole person—I confess the fictions of poetry became substantial, and the *beau ideal* of my youthful imagination realized.

But who was the person I have described? A mere statue to adorn a gallery of sculpture? A bird of paradise, to be kept in a glass case? A mere doll, with painted cheeks, to be dressed and undressed with childish fondness? A mere human toy, to languish over romance, or to figure in a quadrille? Far otherwise: she was a woman in the noble attributes which should dignify that name: a wife, a mother, a housekeeper, a farmer, a gardener, a dairy-woman, a kind neighbor, a benefactor to the poor, a Christian woman, "full of good works, and almsdeeds which she did."

In the morning, I first met her at prayers; for, to the honor of England, there is scarcely a family, among the hundreds whose hospitality I have shared, where the duties of the day are not preceded by family worship; and the master and the servant, the parent and the child, the teacher and the taught, the friend and the stranger come together to recognize and strengthen the sense of their common equality in the presence of their common Father, and to acknowledge their dependence upon his care and mercy.

She was then kind enough to tell me, after her morning arrangements, she claimed me for the day. She first showed me her children, whom, like the Roman mother, she deemed her brightest jewels, and arranged their studies and occupations for the day. She then took me two or three miles on foot to visit a sick neighbor, and, while performing this act of kindness, left me to visit some of the cottages upon the estate, whose inmates I found loud in the praises of her kindness and benefactions. Our next excursion was to see some of the finest, and largest, and most aged trees in the park, the size of which was magnificent; and I sympathized in the veneration which she expressed for them, which was like that with which one recalls the illustrious memory of a remote progenitor. Our next visit was to the green houses and the gardens; and she explained to me the mode adopted there of managing the most delicate plants, and of cultivating, in the most economical and successful manner, the fruits of a warmer region. From the garden we proceeded to the cultivated fields; and she informed me of the system of husbandry pursued on the estate, the rotation of crops, the management and application of manures, the amount of seed sown, the ordinary yield, and the appropriation of the produce, with a perspicuous detail of the expenses and results. She then undertook to show me the yards and offices, the byres, the feeding-stalls, the plans for saving, and increasing, and managing the manure, the cattle for feeding, for breeding, for raising—the milking stock, the piggery, the poultry yard, the stables, the harness-rooms, the implement-rooms, the dairy.—She explained to me the process of making the different kinds of cheese, and the general management of the milk, and the mode of feeding the stock; and then, conducting me into the bailiff's house, she exhibited to me the Farm Journal, and the whole systematic mode of keeping the accounts and making the returns, with which she seemed as familiar as if they were the accounts of her own wardrobe.

This did not finish our grand tour, for, on my return she admitted me into her boudoir, and showed me the secrets of her own admirable housewifery, in the exact accounts which she kept of every thing connected with the dairy and the market, the table, the drawing-room, and the servants' hall. All this was done with a simplicity and a frankness which showed an absence of all consciousness of any extraordinary merit in her own deportment, and which evidently sprang solely from a kind desire to gratify a curiosity on my part, which, I hope, under such circumstances, was not unreasonable. A short hour after this brought us in to another relation; for the dinner-bell summoned us, and this same lady was found presiding over a brilliant circle of the highest rank and fashion, with an ease, elegance, wit, intelligence, and good-humor, with a kind attention to every one's wants, and an unaffected concern for every one's comfort, which would lead one to suppose that this was her only and her peculiar sphere.—Now, I will not say how many mud-puddles we had waded through, and how many dung-heaps we had crossed, and what places we explored, and how every farming topic was discussed; but I will say, that she pursued her object without any of that fastidiousness and affected delicacy which pass with some persons for refinement, but which in many cases indicate a weak if not a corrupt mind. The mind which is occupied with concerns and subjects that are worthy to occupy it, thinks very little of accessories which are of no importance. I will say, to the credit of Englishwomen—I speak, of course, of the upper classes—that it seems impossible that there should exist a more delicate sense of propriety than is found universally among them; and yet you will perceive at once that their good sense teaches them that true delicacy is much more an element of the mind, in the person who speaks or observes, that an attribute of the subject which is spoken about or observed. A friend told me that Canova assured him that, in modelling the wonderful statue of the Three Graces, from real life, he was never at any time conscious of an improper emotion or thought; and if any man can look at this splendid production, this affecting imbodiment of a genius almost creative and divine, with any other emotion than that of the most profound and respectful admiration, he may well tremble for the utter corruption, within him, of that moral nature which God designed should elevate him above the brute creation.

Now, I do not say that the lady to whom I have referred was herself the manager of the farm; that rested entirely with her husband; but I have intended simply to show how grateful and gratifying to him must have been the lively interest and sympathy which she took in concerns which necessarily so much engaged his time and attention; and how the country could be divested of that dullness and *ennui*, so often complained of as inseparable from it, when a cordial and practical interest is taken in the concerns which necessarily belong to rural life. I meant also to show—as this and many other examples which have come under my observation emphatically do show—that an interest in, and a familiarity with, even the most humble occupations of agricultural life, are not inconsistent with the highest refinements of taste, the most improved cultivation of the mind, the practice of the polite accomplishments, and a grace, and elegance, and dignity of manners, unsurpassed in the highest circles of society.

Life in the Country.

The following exquisite gem we take from the third number, just published, of Colman's European Agriculture.

"To live in the country, and enjoy all its pleasures, we should love the country. To love the country is to take an interest in all that belongs to the country—its occupations, its sports, its culture, and its improvements, its fields and its forests, its trees and rocks, its valleys and hills, its lakes and rivers; to gather the flocks around us, and feed them from our own hands; to make the birds our friends, and call them all by their names; to wear a chaplet of roses as if it were a princely diadem; to rove over the verdant fields with a higher pleasure than we should tread the carpeted halls of regal courts; to inhale the fresh air of the morning as if it were the sweet breath of infancy; to brush the dew from the glittering fields as if our path were strewed with diamonds; to hold converse with the trees of the forrest, in their youth and in their decay, as if they could tell us the history of their own times, and as if the gnarled bark of the aged among them were all written over with the record of by-gone days, of those who planted them, and those who early gathered their fruits; to find hope and joy bursting like a flood upon our hearts, as the darting rays of light gently break upon the eastern horizon; to see the descending sun robing himself in burnished clouds, as if these were the gathering glories of the divine throne; to find in the clear evening of winter, our chamber studded with countless gems of living light; to feel that "we are never less alone than when alone;" to make even the stillness and solitude of the country eloquent; and above all, in the beauty of every object which presents itself to our senses, and in the unbought provision which sustains, and comforts, and fills with joy, the countless multitudes of living existences which people the land, the water, the air, every where to repletion; to see the radiant tokens of an infinite and inexhaustible beneficence, as they roll by us, and around us, in one ceaseless flood; and in a clear and bright day of summer, to stand out in the midst of this resplendent creation, circled by an horizon which continually retreats from our advances, holding its distance undiminished, and with the broad and deep blue arches of heaven over us, whose depths no human imagination can fathom; to perceive this glorious temple all instinct with the presence of the Divinity, and to feel, amidst all this, the brain growing dizzy with wonder, and the heart swelling with an adoration and a holy joy, absolutely incapable of utterance;—this it is to love the country, and to make it, not the home of the person only, but of the soul.

Original Communications.

Manures.—Do they Sink or Evaporate?

Mr. Editor:—In the last number of the Cultivator, you invite planters and farmers to write out their experience for publication, not stilting themselves on "big words" from the dictionary, but in plain language, such as would be used in talking with each other, you kindly promising to correct errors in spelling and grammar. Emboldened by the invitation and promise, and holding you to the latter, I address myself to the work proposed, and although I give no experiments of my own, I hope to make some useful remarks on the experiments of another, to wit: a brother farmer (at least I suppose he is one) living over in South Carolina, who writes for the Temperance Advocate, (an excellent paper that, I know from its name,) and whose essay you republished on page 70 and called it "excellent." Now, I am a farmer, and want to talk to friend "Coatswood" (the writer referred to) as if we were neighbors, and had just met and were sitting on the dividing fence between our farms, or just out of the field on a log in the shade. But as I can't write a dialogue, I must do all of the talking myself, and beg your indulgence, Mr. Editor, if I write in a disconnected and desultory manner.

Every farmer will concur with the South Carolinian in advising that manures be so applied as to secure their most lasting benefits, as well as in the caution to guard against waste. But in determining as to the best means of doing the one, or avoiding the other, many things must be kept in view, such as the kind of soil and subsoil, the sort of crop, the mode of cultivation, &c.—points on which I shall say but little or nothing *now*, only so far as may become necessary in discussing the question, "does manure ever sink?" or rather, in reviewing certain experiments made to sustain the negative of that question.

Coatswood denies that it can sink, and proceeds to the proof on this wise: He fills a cider barrel nearly to the top with clean sand, then pours on the sand the "most impure liquid manure;" after which he is able to draw off "nearly pure water" from a hole in the lower end of the barrel. He says, too, "the impurities which constitute the manure will have been detained by the sand, by filtration, within a short distance of the top of the barrel." Right curious, this! If C. economises no better in other things than he does in labor-saving, he will not do for a teacher in agriculture. Two and a half feet of sand in the barrel, and the manure detained by the sand within a "short distance" of the top! Now, it seems to me that a "short distance" of sand in the barrel, say six inches, would have saved two feet of labor, i. e., the labor of putting in the two feet of *unnecessary* sand. For I suppose he will admit that six inches, perhaps less, is a "short distance" of sand. But peradventure he had some apprehensions that with less than a barrel full of sand, the water might not have been *quite so pure* as it was; and he says it was "nearly pure," not perfectly. Next I would inquire what does C. mean by impure liquid manure? He certainly does not mean wine, for in filtering that article, "I guess," he would not have found much of the impurities about the top. I suppose something from a Bommer vat, or perhaps a bucket of water brought to the consistency of unboiled mush by due admixtures from the stable, or cowpen, or henhouse, would make the liquid experimented with. At all events either of these will do, on the score of impurity, for such an experiment; and we (repeating the experiment) take some and throw it up, the water sinks, the fibrous, earthy, and such like parts constituting the chief bulk, remain on top; the finer parts of decomposed matter sink deeper, and the still finer deeper still, until the water gets to the bottom and is drawn "from the spigot (he means the hole) nearly pure water"—that is, freed from all the grosser animal, vegetable and earthy impurities, but still holding in solution or suspension some organic matter and all the soluble salts which the manure contained—salts highly prized now-a-days for their fertilizing properties—and he will not deny, "in this day of enlightenment," that they possess such properties. But, if he does, I wash my hands of his agricultural heresy and turn him over to Liebig to be better instructed. Salts can't be separated from water by filtration. Distillation and evaporation, which are nearly the same in principle, are the only means by which it can be done, (except some little things in this line that chemists sometimes do, and which are entirely irrelevant) No, friend Coatswood, you can't do it; at least this is my opinion. But if you can, your fortune is made. "All that a man hath will he give for his life." Let mariners know your success. Let all cumbrous water casks be given to the waves, and your filter be used in their stead, and then famishing at sea for fresh water will never happen until the ocean dries up.

C. next says it is upon this principle that farmers clarify cider, grocers purify wine, and confectioners do *something*, that is not printed for our edification. But I guess the cider remains sweet, and the wine alcoholic, after the process, each retaining every essential quality and constituent, otherwise it would be a losing business to them, and proof against me.

"If we look at the operations of nature," says C., "we shall recognise it there. If the impurities on or near the surface of the earth were carried down by rain, we should never be able to get a palatable drink of water." Now, that is a fact: just the thing I am trying to prove. If you will come down here, friend C., into our flat piney woods country—where the whole face of the earth is too level for water to run off, and as porous and sandy as that barrel you "fixed"—and drink some of our best water, from gushing springs and wells, as you poetically call them, you will conclude with me, that you never wrote or uttered a truer sentiment in your life, for the best is bad indeed, from the cause above stated, and the bad, though strained of wiggle-tails, is yet decidedly "unpalatable."

The next experiment I notice is a bottomless box, filled with manure, and put on a stone, exposed to sun and rain. In reference to which our writer says, "a method which I select as rendering it certain that no part can sink"—a sentiment in which I most heartily concur with him. But he will find that there is another way of "escape" besides "at the top," if he will go to the box the next rainy day, and see the rich looking ooze (tobacco chewers know the color) that flows from it. An ooze that hundreds of us misguided and ignorant country people use to water and enrich our plant beds, imagining it is the strength of the manure, so far as decomposition has disengaged its strength, and *roundly asserting and pertinaciously maintaining* that plants grow faster, get bigger, and look better by its use than those in the next row that receive no such attention.

Friend C. next says, manure exposed "to sun alone will in a very short time become entirely inert." If this be so, Mr. Editor, you, as a benevolent man ought to give extensive publicity to it, and save from unnecessary labor and exposure the thousand mariners that frequent the sunny little island of Ichaboe to procure that worthless stuff Guano, which has been accumulating there since the days of our great grand father Noah.

Our essayist says manure is sooner lost on sandy than on clayey land, and accounts for it by the greater heat of the former producing increased evaporation. I admit there is more or less lost in any kind of land by evaporation, and more in sandy than in clayey lands. This is partly owing to the greater heat, and partly to the want of tenacity in the former, facilitating its escape upwards or downwards, as rain or sunshine may favor the one or the other, By leaching ashes we get ley, the water percolates (allow one dictionary word) the ashes, dissolves the potash, and comes out ley, or potash in solution, and in this solution are many impurities. Is it any more strange or unreasonable that the strength of manure should sink more or less in any land, but especially in sandy lands which have not a good clay or "stone" foundation? If manure don't sink, how happens it that corn is so much benefited by it when thrown on the top of the ground around each hill, and that too before the manure is covered with earth? Why is the water "unpalatable," where there are large districts of very rich land, especially level land, whatever may be the nature of the undersoil or *substratum*, if salts can be filtered out, and organic matter never sinks? Why the deterioration of water in cities and even in some of our country towns, which have been long built and densely populated?—How does a meathouse near a well injure its water? Let C. answer these, and it will be an answer to a hundred kindred questions that might be propounded. Professor Brande says, he "frequently found the wells of London contaminated by organic matter," and Dr. Clark, professor of Chemistry in Marischal College, Aberdeen, states "that the organic matter which passes into the water from sewers is *not separable* by filtration." The analysis of other waters would show the same result. Indeed, for some water no chemical test or apparatus is needed. The tongue and the nose decide the question.

Mr. Editor, that abominable tyrant, Fashion, rules in other things besides dress, furniture, equipage, &c.; he invades our ancient, honorable and independent province. I deny his right, and abjure all allegiance to him. He now says, every thing like manure exhales or evaporates. What will he say next?

One interpolated extract from friend Coatswood and I shall be done for the present. "I have shown that manure does" sink as well as evaporate, and does both "more rapidly from sand than from clay. What is the necessary inference? Is it not that the practice of making a shallower deposit in sand than in clay" should be continued where there is not a good clay foundation. *May*, 1845. Salamander.

Bermuda Grass.

Mr. Camak:—I have seen in the various periodicals of the day, a number of communications upon the subject of Bermuda Grass; and as I have, perhaps, had more dealings with that grass than any man in the country, permit me to give you the result of my experience with that "critter." I have had the Bermuda grass on spots of my land for seventeen years or more, and I have tried all reasonable ways to destroy it, but I have found only one plan to succeed: and that is, to plow it up in the winter, two or three times, deep and well; in the spring, after it puts up, with the aid of a mattock under its roots, pull up every living particle that can be found, shake the dirt well out of its roots, and expose it to the hot sun for several days, then turn it over and expose it again in like manner; plow the ground again; let it lie until what grass is left comes up tolerably well; treat this crop as before, and repeat. This course, in two years, will effectually destroy it. Never disturb it with the plow or hoe only expressly to destroy it.

The idea of destroying it by covering it up, or by sowing the ground in small grain for several years in succession, or by cultivating the ground in any other way, is all a notion founded on inexperience. I have covered it over with green pine brush, cut small, laid close as possible, and packed hard, waist deep, and have adopted various other plans to destroy it, but none have succeeded at all, at all, but the plan before mentioned. Covering it over well with brush, green or dry, and letting it remain there a month or two, and then burning it off, or burning log heaps upon it in order to destroy it, I know, from experience, to be labor lost. Planking it over, as some have suggested, and breaking the joints, to say nothing of the expense of the project, is all nonsense. The idea has gone abroad that it will not grow in the shade, in briar beds, nor in the woods. This idea is partly true. It does not grow so well under these circumstances, nevertheless I can show it growing under all these circumstances. I can show it growing in a briar bed that reminds me of Fall's thicket, so dense "he could not stick a butcher knife in it;" and yet it grows luxuriantly, and is now from knee to waist high, and thick as grass gets to be.

It is said to enrich land. This may be true, but I have never reaped any benefits from it in this way. All the profits that I have ever realised from it, in any way whatever, have come to me "over the left shoulder." Some say it makes first rate pasturage. My experience upon this point is this: I have an acre of ground in front of my house covered with it, and another acre at the end of my house that has but little of the Bermuda grass upon it. On an average, I find ten head of stock grazing upon the acre that has but little of the Bermuda grass upon it, to where I find one head of stock feeding upon the Bermuda acre, notwithstanding the Bermuda acre is well matted and always affords good grazing, whilst the other acre is kept fed to the ground. I have a calf pasture of about ten acres, tolerably well spotted over with Bermuda grass, and the balance of the ground is covered with broom sedge and other spontaneous productions. The Bermuda is often suffered to head whilst the other grass is kept cropt to the ground.

It is possible that the Bermuda grass is nutricious, and does stock admirably well when they can get nothing else to eat, but it is not their choice grass.

The Bermuda grass is destined to ruin this country unless the arm of the law interposes a barrier to its dissemination, by imposing the heaviest kind of penalty upon him who dares to spread it. Once rooted in a yard, or on any portion of a plantation, and it is as good to take that plantation as a sevenpence is for a half pint.—Look at the fine plantations destroyed about Hillsborough, Powelton and other sections of the State by this grass; and is it reasonable to suppose that the owners of these fertile lands would have surrendered them to this grass if they could have arrested its course? Not they—too much sense had they to enter into any such speculation. JOHN W. PITTS.

Newborn, Ga., June 6, 1845.

Bermuda Grass.

MR. CAMAK:—My experience with Bermuda Grass commenced some eight years ago. When I came to Athens my lot was completely set with it; and about three quarters of an acre was an old field which appeared to have been worn out, and had not been cultivated for several years. In the month of August, I enclosed it, and sowed it in wheat and turnips. I had through the winter a very fine crop of turnips; and in the month of June following I harvested eight bushels of fine wheat. In the fall I plowed it, and in March planted it in corn, putting the drills seven feet apart. I plowed the corn twice, running three furrows next the corn, and leaving the middle of the rows undisturbed. In the course of the summer, I cut and saved at least five hundred pounds of as fine hay as I could have wished for; and in the fall gathered about four barrels of corn. I have cultivated the land ever since, and have never put one spoonful of manure on it; and I have never failed to make a fine crop of corn, peas and beans; and I believe the land is much better now than it was the first year I cultivated it, and produces more.

The land lies somewhat rolling, and there is not the beginning of a gully in it. This then is another advantage to land, that Bermuda grass effectually prevents it from washing.

Again, my lot and yard were thickly set with this grass. I planted my yard in fruit trees—peach, apple, pear and cherry trees. They have done well, and bear fine fruit without cultivation; and every farmer knows that broom sedge will destroy an orchard in a few years if not cultivated.

In order to destroy Bermuda grass, cover it with plank, chips, or pine brush, and you will soon get clear of it.

I find it to be the finest grass I ever had for my horses, hogs and cows, and even chickens. But keep it out of your garden. I have dug my Irish potatoes and found it had grown through some of them. JOHN FELTON.

Athens, May, 1845.

Bermuda Grass.

Will the Editor of the SOUTHERN CULTIVATOR, or Mr. John Cunningham of Greensboro, or any others who have had experience on the subject, please answer, through the columns of the SOUTHERN CULTIVATOR, the following inquiries?—viz:

What would be the expense of enriching land by planting Bermuda Grass and turning it under, compared with the outlay required when leaves and other like substances are used?

Would not the expense of planting, turning under, and *extra labour* in tending the land after the grass, be *less* than the cost of manuring land by any other means of which we have any knowledge?

May not Bermuda Grass be made to do for the South, all that clover does for the North?

After the Bermuda Grass has been turned under will it require more labour to tend the land than it would if it was well stocked with crab grass? Respectfully, P.

Monroe, Walton Co., Ga., June, 1845.

A Grape Crop safer than most others against injury by late Frosts and Drouths.

Most kinds of grain are sometimes injured by late frosts in the spring, and most kinds of fruit, as apples, peaches, pears, &c., are sometimes destroyed thereby, as was the case on the night of the 8th of April, in this region of our country. But the prospect of a grape crop is now as good as if no such frost had occurred; for the grape leaves and blossoms, for the most part, had not put forth. Again, there is something peculiar in the formation of blossoms and fruit on grape vines; as they are capable of an entire new growth the same season. Hence, if all the leaves and blossoms are destroyed by a frost, they will come out again, and a crop ensue notwithstanding; as in the case mentioned by the late Mr. Herbemont, of Columbia, S. C., where grape vines are more subject to injuries by late frosts than here. His entire crop of grapes he once considered ruined, as the blossoms and all the foliage on his vines were destroyed; but an entirely new growth produced abundantly. In my experience of more than a dozen years, I have never failed of a grape crop from late frosts, or any other cause; though some foreign varieties I once cultivated, and some American kinds, as the Isabella and Catawba frequently rotted on the vines ere maturing. This evil I obviated by cutting off in the fall (spring grafting to stocks unremoved is not apt to succeed,) the most of the rotting kinds, and grafting into their stocks those not liable to this misfortune, such as my Halifax, Norton's V. Seedling, Vine Arbour, &c.

And I add here, that a grape crop stands a drouth, in this region, better than most other agricultural products. Last season a pretty severe drouth, in a critical time for grapes, or just before most kinds ripen, caused a few only of some varieties to drop prematurely, while other kinds were not affected. True, last season I was cut short of as full a crop of wine as I expected by about ten barrels; or I made but thirty instead of forty. But this was mostly owing to a severe storm, of some days continuance, here called a gust, which blew down grapes enough for several barrels of wine. The fallen fruit was, for the most part, eaten by swine, always kept in my vineyards for such purposes, and that of helping to keep the ground scarified beneath the canopies.

I here take occasion to remark, that to those having the foresight and industry to take pains for it, a vineyard is a sure source of most pleasant and healthful fruit, for a number of months in the year, and that, too, when other sources sometimes entirely fail. Nothing more healthy do we find than well selected ripe grapes. In view of the general good health of my family and others in the abundant use of grape fruit, and that too in part of a sickly time of year in this region, I wonder not at the account of unhealthy persons, in parts of Europe, being sent for their recovery to the vineyards in Switzerland to subsist entirely for the season on a grape diet. And when we consider the very great benefits of pure wine to the human family and its happy tendency, when temperately used, to counteract the direful effects of unhealthy food, luxuries, intemperance, and disease, I wonder not that wine is called by most eminent physicians the greatest of medicines, and that the unerring voice of inspiration puts it along side of bread itself, the staff of life. And seeing the great excellency and zest of good wine, and the unhappy proneness of human beings to pervert and abuse all blessings of Providence, (the greatest often most liable thereto,) I wonder not at the emphatic warnings of the greatest moralists, and of the same unerring voice of inspiration by way of caveat; and putting the abuse thereof for the article used, calling wine a "mocker," as well as representing strong drink "raging." This is analogous to the same volume of inspiration, (not like the impostor Mahomet's false revelation denouncing a blessing because of its liability to abuse,) representing *money* or property, a blessing in itself considered, but the *love* or *idolatry* of money as the root of *all*, or (apart from the figurative language) of *most kinds of evil*. And that scripture wine was really so, or fermented, and not mere grape juice, as some vainly contend for, is quite evident from its declared abuse and the very warnings of the bible against drunkenness thereby. But scripture wine was *indigenous* to the country where made, and therefore not liable to the *adulterations* and *injurious* effects of *foreign importations*.

And may I be suffered here to remark, in conclusion, why not Americans (in a country where native vines grow more luxuriantly than elsewhere,) make their own wines, and save annual, millions of foreign dependence for the article, that properly made and used, like in eastern wine making countries, known to be the most temperate in the world, is more unequivocally good, pleasant, healthful and medicinal than any of foreign importation?

In expressing these moderate and scriptural views on the subject just touched upon, I am perfectly aware I am liable to offend *ultraists*; or certain classes of people in our day of extravagant excitements, who run from one extreme to another, seeming to *abhor nothing worse than the golden medium*.

We have now rife in our country the abolition humbug, tending to sacrifice the liberty and happiness of all our *white population* for the *fancied* good of the *blacks*. And the humbug of abolishing capital punishments, tending to sacrifice the lives of virtuous citizens to cheat the gallows of its dues as to murderers and cutthroats. And not the least of the ultraisms of the day is, the *temperance* one of *intemperately* denouncing *all liquors*, without exception, and their use. And if all the aforenamed tirades of far worse than refined nonsense, were hurled against human inventions only, I would not here protest. But I am bold to aver that they are not only against the universally benign experience of mankind in all ages, (and so the voice of Providence,) but most clearly against the plainest authority of the word of God.

Most respectfully yours, &c.

SIDNEY WELLER.

Brinckleyville, Halifax co., N. C., May, 1845.

Information Wanted.

MR. EDITOR:—The subject of this short communication, is simply to elicit through the columns of your interesting paper, information concerning the proper tillage of some grass,—timothy, clover, or any other, such as the correspondent, who may deem it necessary to answer this small request, shall think best adapted to the soil and climate of the interior of South Carolina. To the writer, who will comply with the above request, I give my obligation to procure the seed recommended, follow his directions as close as possible, and report the results of my attempt—viz:

The soil, preparation, and manner of planting.
The quantity of manure—per acre.
" " " seed "
Mode of cultivation, and seasons for mowing.

Such information, reported through the CULTIVATOR, will be thankfully received by your humble subscriber. D. G. WOOD.

Jeffrey's Creek, Darlington, S. C., May, 1845.

Palma Christi.

MR. CAMAK:—A friend of mine has requested me to ask, through the columns of the CULTIVATOR, for instruction in the manner of raising the Palma Christi, or castor oil plant:—how the seed are prepared for the press, and what sort of a press is used? If he can get the proper instruction in the business he will go into it.

While writing, I will say a word or two on the manner of raising the sweet potato. I saw last year the result of an experiment which did extremely well. The vines were cut off from some part of the patch, daily, and given to the hogs; and this was their principal food, until all the vines were taken off within 12 to 18 inches of the root. The ground cracked very

much; and, at digging time, a crop was housed superior, by at least one third, to any that had ever been raised on the same farm, on the same quantity of land. Yours, WILLIAM DAVIS.

St. Pauls, N. C., May 27, 1845.

Batter Cakes.

MR. JAMES CAMAK:—Since commencing to keep house, some month or so since, my wife has been giving me a batter-cake with which I am so much pleased, and it is so simple and so easy to make, that I am induced to send the receipt to you for your valuable paper, should you choose to insert it therein. I have never seen the same thing any where else, although it may be used by many in some sections of the country. This is the receipt for making a cheap and excellent batter-cake—better than buckwheat, viz: Make a mush of Indian meal, work it well, and let it get cool. To 1 pint of milk add 3 or 4 table-spoonsful of the cold mush, then add a little flour, to make it of the proper consistence for batter, 1 tea-spoonful of fine salt, ½ tea-spoonful of saleratus, and 1 egg if you have one, if not it does very well without, and cook as any other batter-cake on a greased griddle.

A YOUNG (Green Co.,) HOUSE KEEPER.

From the Dollar Farmer.

A TREATISE ON THE THEORY AND PRACTICE OF LANDSCAPE GARDENING, ADAPTED TO NORTH AMERICA, WITH A VIEW TO THE IMPROVEMENT OF COUNTRY RESIDENCES: By A. J. Downing: *Second Edition.*

This edition of this valuable and interesting work, which has but recently reached the West, presents it enlarged, revised, and ornamented by many new illustrations. It may be considered now as a very complete work, and we regard it as far the most valuable and interesting contribution ever made in this country to that class of the community to which it is specially addressed, not excepting the great works on agriculture which have distinguished this period.

We are particularly desirous of recommending this work to the attention of our readers. Much as we feel it our duty to keep them advised of all the discoveries, experiments, and improvements in agriculture, we believe that we should render them, at least those in good circumstances, a far more valuable and permanent service by simply inducing them to purchase and study this treatise on the art of adorning their homesteads, and on the principles of taste in rural scenery. By communicating such information as might enable them to increase their crops, the wealth of those who avail themselves of such information might be augmented; they might thus gain a pecuniary advantage over their neighbors who disregard such information; but it is by no means certain that their happiness, much less that of the great mass of farmers, would be increased. On the hypothesis that they become richer, the sum of their pleasure or happiness would depend at last on the manner of using the increased wealth; and nine times out of ten there would be no increase of the enjoyments of life. With regard to that large class who either cannot or will not avail themselves of the information in question, the increased production of their richer or more enterprising neighbors would be a decided injury by lessening the value of their own productions.

But the diffusion of a taste for rural scenery would produce unmixed and universal benefits. The happiness of those induced to adorn their homesteads would be increased in a degree far beyond the power of the mere accumulation of wealth. Any kind of occupation prevents ennui, but the occupation of landscape gardening partakes of the rapturous delights felt by the painter or poet in reducing to paper or canvass the visions of the imagination. Landscape gardening is as much a fine art as either painting or poetry, and it differs from these in this, that all have more or less the talent to practice it, and that there is more general capacity to enjoy its effects.

With regard to persons in poor circumstances, a taste for improving the country would promote their interests by producing a demand for labor, and by diverting labor from productive occupations and slackening the competition among producers. The blighting effects of great competition are nowhere better illustrated than in the cotton region, where all the comforts and delights of life are sacrificed in a struggle to make money, and where the struggle to make money plunges the people every day deeper in debt and poverty. If one half the labor of the South were diverted from cotton to the production of the comforts and elegancies appertaining to a high state of civilization, not merely would the enjoyments of life be infinitely multiplied there, but the wealth of the country increased.

The great obstacle to real social amelioration, to progress in genuine civilization in this country, is the inordinate thirst for gain, and the want of local attachments. In general it may be said that in the South and in the new western States the only object of the cultivator of the soil, after supplying the actual wants of subsistence, is to increase in wealth. With this object alone in view he makes a settlement, and he removes to a new farm the moment he can make a dollar by the exchange. He seems to make his temporary home as cheerless as possible, in order that no love of it may interfere to prevent his migration whenever he believes he can make money by it. No sentiment, no attachment is allowed to take root that may possibly interfere with the one object of amassing riches. He builds a cabin of logs barely tight enough to keep him from freezing, he cuts down every tree and shrub within a quarter of a mile, he surrounds it with a worm-fence, and with the plowshare he defaces every vestige of natural beauty up to his very door sill. In the South, cotton and corn, in the West, corn, flax, and hogs, are his only care. He cultivates no vegetables but cabbages and turnips, and no fruit of any kind; for fruits and the more delicious vegetables are not necessary to support life, and the cultivation of these would flatter pleasure, divert the mind from the one object of life, and beget an attachment for the soil, a sentiment of home and the delights of civilized life.

It is this migratory spirit, this sordid love of money, this worse than savage destitution of the love of home, attachment to the soil, and all the elegancies, refinements, and charms of civilization, that is tempting the people of this country to pass beyond its bounds and seize the ample domain of Texas; and one of the greatest, with us far the greatest of all objections to the annexation of Texas, is this, that it will tend to increase this Tartar spirit. Would that a wall were built up about us, on the south and on the west, that the living tide might be staid, and that our people might subside into civilization, and the love of home, the sentiment of patriotism, the amenities and tastes of a high state of cultivation, find a place in their hearts. The work before us, if widely circulated, would be a powerful auxiliary in this great social reform. Nothing tends so much to fix men to the soil, to nourish a love of country, to quench the all-consuming and all-destroying love of money, to cherish the amenities and charities of life, and generally to dignify and elevate man, as a taste for horticultural pursuits and rural scenery.

II.

From the South Carolinian.

RURAL ECONOMY. In its relations with Chemistry, Physics, and Meteorology, or Chemistry applied to Agriculture. By J B Bousgingault, Member of the Institute of France, &c. Translated with an introduction and notes by Geo. Law, Agriculturist. New York: D Appleton & Co. pp. 507.

This work gives the results and enquiries in which the author was engaged for many years, relative to the advancement of practical Agriculture. The first part of the work treats in succession of the physical and chemical phenomena of vegetation; of the composition of vegetables and their immediate principles; of fermentation; and of soils. The second comprises a summary of all that has been done on the subject of manures, organic and mineral; a discussion of the subject of rotations; general views of the maintenance and economy of live-stock; finally, some considerations on meteorology and climate, on the relations between organized beings and the atmosphere. A summary view is given of all the questions of rural economy that admit of scientific treatment. Books of this character now find admirers with all kinds of readers; and we see the whole world, from the pent-up dweller of the city, to the wild, free woodsman, excited as to researches into the mysterious and instructive kingdom of nature. We think it argues a good omen, for the prosperity of our extensive nation, that readers of such works, read them almost exclusively for the benefits which they bestow on our domestic comforts, and look to flattering results, from the even increased interest attached to researches bearing upon practical agriculture, and like the author, must "hope for conclusions important as regards science, profitable to practice, and useful to humanity." We shall make extracts from this work for our agricultural department, which will more fully show to our readers its inestimable value to the practical Agriculturist.

III.

STABLE ECONOMY: A Treatise on the Management of Horses, in relation to Stabling, Grooming, Feeding, Watering and Working. By John Stewart, Veterinary Surgeon, &c. From the third English Edition, with Notes and Additions, adapting it to American food and climate. By A. B. Allen, Editor of the American Agriculturist. New York: D. Appleton & Co.

The Horse! friend of Humanity! loved by the lazy! admired by the tasty! who does not turn with pleasure to the contemplation of a work, which treats of those means best adapted to improve his usefulness and preserve his incomparable powers? Mule and donkey, both can take care of themselves, but the horse, a creature of delicate powers when mismanaged, can be trained to the endurance of wonderful performances, by the proper knowledge relative to the wants of his constitution and peculiarities. By careful breeding and training, his strength, speed, and endurance have been wonderfully increased. Agents employed have been numerous, and their power has not been limited to one change alone, but varying according to circumstances, such as duration and repetition of their operation, and the condition of the animal at the time he is operated on. Much of this and the improved value of a well trained harness horse is owing to proper treatment from the groom, who may, by understanding the peculiar wants of an animal, from his constitutional organization, render him extremely valuable—and from the contrary cause, ignorance, may entirely ruin a good animal. All these things render the horse an eminent study—not only for his improvement, but for the benefits which may be conferred on the community by the prevalence of the best breeds for the different purposes for which they may be wanted. We have seen a Canadian pony, weighing seven hundred weight, which could and did draw in our presence, more than four times his own weight of stone, on a common cart in the streets of Montreal, up a considerable hill. These ponies have speed, endurance and good action—and living on less and coarser food than is given to the worst fed mules of this country, they are valuable in an economical point of view to their owners.

Of what benefits could we count on receiving, if such a breed of horses were introduced amongst us? Would they not soon supply the places of our large and almost worthless Kentucky horses, which "eat off their heads" before they become acclimated, and are fit to do substantial service. There is not a single strain of the Canadian blood incorporated amongst the many breeds which obtain amongst us. Good roads would tend, too, to improve the breeds of draught horses more than any one thing which we could do. The book, the title of which stands above, gives us suggestions as to all these matters—in fact, it teaches us every thing, from the construction of stables, their ventilation and appendages, to stablemen, grooming, and operations of decoration, management of the feet, &c.

It also treats of restraints, accidents, habits, vices, &c., warmth, food, water, service—which comprises general preparation for work, physiology of muscular exertion, preparation for fast work, preservation of working condition, treatment after work, accidents of work, kinds of work, repose, &c.; and closes with an admirable chapter on the management of diseased and defective horses, colts, &c.

The name of Mr. A. B. Allen is a sufficient guaranty to the American public of its adaptation to our wants and climate, and its general utility.

Dr. LEE, of Buffalo, asserts that 97 per cent. of the food of plants is derived from the atmosphere, and only 3 per cent from the soil. That a great amount is so derived has been long known. And yet the want of some single ingredient in the soil may prevent a plant from eliminating for its use this amply supply of atmospheric food. How important, then, that we should know the constituent elements of different plants, in order that we may supply each with its appropriate food.

Agricultural Meetings.

Burke County Agricultural Society.

WAYNESBORO', *April 1st*, 1845.

Agreeable to previous notice, a respectable portion of the farmers of Burke county assembled in the court house on Tuesday, 1st of April, 1845, when, on motion of Samuel P. Davis, George W. Evans was chosen Chairman, and Joseph A. Shewmake appointed Secretary.

Mr. J. B. Jones, in a few brief and pertinent remarks, stated the object of the meeting to be the organization of an Agricultural Society, and concluded by moving that a Committee of Seven be appointed by the Chairman, to draft a Constitution for the government of the Society.

The Chair appointed the following gentlemen that Committee, viz: Joseph B. Jones, Dr. Baldwin B. Miller, Judge John Carswell, Samuel P. Davis, M. C. Hammond, John Dowse, and Edmond Gresham.

On motion of Mr. Gresham, the Chairman was added to the Committee.

On motion of Mr. Hammond, the Committee was given until the first Monday in May to make their report.

On motion of Judge Whitehead, the meeting adjourned to meet on the 1st Monday in May.

JOSEPH A. SHEWMAKE, Sec'y.

May 5th, 1845.

Pursuant to adjournment, a large number of the citizens of the county assembled in the court room, to receive the report of the Committee appointed at the former meeting to draft a Constitution for the Society. Col. George W. Evans being in the Chair, Mr. James Jones was on motion appointed Secretary. Mr. Joseph B. Jones, Chairman of the Committee, then reported a preamble and constitution for the Society, which being twice read, and amended so as to allow any citizen of the State, planting in Burke county, to become a member, was, on motion of Mr. John Dowse, adopted.

The Hon. Chas. J. Jenkins, of Augusta, having been previously requested to address the Society, was waited upon by a committee consisting of Messrs. C. W. West, Mulford Marsh and Andrew Carson, to ascertain at what hour of Wednesday he could address the Society.

On motion of Jos. B. Jones, a committee of five was appointed, viz: Messrs. Jos. B. Jones, C. W. West, John Dowse, Andrew Carson and Benjamin E. Gilstrap, to nominate officers and an orator, to be elected on Wednesday by the Society.

The committee appointed to wait upon Mr. Jenkins, having reported the hour of one o'clock of Wednesday as the one appointed by him, the Society adjourned to meet at that time.

JAMES JONES, Sec'y.

May 7th, 1845.

The Society met pursuant to adjournment. The regular Chairman being absent, on motion, Mr. Thos. M. Berrien was requested to preside over the meeting, and Mr. Alexander MacKenzie was requested to act as Secretary.

Hon. Charles J. Jenkins then delivered an address on the subject of agriculture, of much beauty and practical worth.

The committee appointed at the previous meeting to nominate officers for the Society, reported the following nominations, viz: for President, George W. Evans; for Vice-Presidents, Andrew J. Lawson, John Whitehead, Baldwin B. Miller, Augustus H. Anderson; Corresponding Secretary, Quintillian Skrine; Recording Secretary, James Jones; Treasurer, John Carswell; Orator, M. C. Hammond.

On motion of Mr. Skrine, the report of the committee was adopted.

The hour for the sitting of Court having arrived, the Society, on motion of Dr. West, tendered their thanks to his Honor Judge Schley for the use of the court room, and adjourned to the first Tuesday in June.

ALEX. MACKENZIE, Sec'y. pro. tem.

Agricultural Society of Barbour Co., Ala.

At a meeting of the Agricultural Society of Barbour County, held in the Town Hall, on Wednesday, 14th day of May, 1845, pursuant to adjournment, Reports of the different Committees appointed at the last meeting were received, read, and ordered to be placed upon the journal of said Society.

To Col. A. MCDONALD, President of the Barbour County Agricultural Society:

SIR:—The Committee appointed at the last meeting of your Society, to examine the gardens in the town of Eufaula, beg leave to submit the following report:

Owing to the absence of some of the Committee during most of the time since their appointment, they have not been able to make so thorough an examination as they could have wished. They have, however, performed that duty, so far as the shortness of their time would permit, though under the most unfavorable auspices, arising out of the long dry spell which has just past. The Committee are happy to state, that they find more general attention being paid by the citizens to the cultivation and improvement of their gardens than heretofore—as well to the ornamental, as to the fruit and vegetable department; but we may suggest to our fair friends, the ladies, that there is still room for improvement, especially when we consider that it contributes so much to the comforts of the table, and those milder gratifications, affording no less pleasure to the senses of smell and sight. The vegetable gardens are well arranged and supplied with every article common to this section, and in a fine state of cultivation, though they do not present as fresh and growing an appearance as they would have otherwise done, owing to the long drouth. And the committee may be permitted to specify some articles that are comparatively rare in this section.

They found at Mr. Thos. Flournoy's the rhubarb growing finely—this article is used for making tarts, pies, &c., and much prized by those having fine tastes; they also saw strawberries of several kinds in a state of great perfection.

Col. McDonald's garden presents the freshest and most luxuriant appearance of any that the Committee have seen. He has a very great variety of vegetables, as well as rare fruits and flowers, some of which he imported; and the Committee must say that he deserves great credit for his energy in this interesting department of culture.

Mr. Young excels in the fruitery; he has blue and green gages so much prized at the North. Pears, peaches and apricots all growing on one stem; cherrys, apples, China oranges, and last, though not least, the alpine strawberry larger than a partridge egg.

Mr. Calhoun has the finest raspberries, some new kinds of squash, and all the varieties of the alium; also, an asparagus bed in preparation. He sows the seed broadcast in common earth, the next spring they are to be taken up, and the bed to be thrown out to the depth of a foot and a half, then laid at the bottom with brick, then filled with common earth, well mixed with manure, and the root set very deep; they are then allowed to grow for cutting. Mr. Paulim informs us of another plan which he regards as being better, which is simply to sow the seed in rows one foot and a half in width—the next spring, excavate about a foot in width and a foot and a half in depth between the rows, fill it up with manure, and let the earth thrown up be for a top covering—this is easier and more simple, and regarded as preferable. Mr. P. has the old field plum in a state of cultivation, and much improved by it, as the Committee can testify by having consulted freely their sense of taste.

Gen. Welborn has the Cuba strawberry, and a very pretty ornamental garden; saw there four live oaks, transplanted from the coast of Florida by Col. Cochran.

Dr. Battle's garden is good, but he is more skilled in the useful than the ornamental. The same may be said of Col. Hunter. General Shorter's garden does not present so fresh and growing an appearance as some others, but more forward. He has squashes, cucumbers, Irish potatoes in great numbers, and what is rare at this season, the summer turnip; also, the rannier, which is not common; the fruitery is well supplied, and the ornamental not excelled by any. Here may be seen oleanders, Cuba lillies, several kinds of the geranium, and the wax plant, now in bloom, and possessing rare beauty. The senior editor of the Shield has some skill in other departments than that of typography; judging from appearances, we should say that he was a *gardener* by *nature* as well as by *name*.

The Committee would have been pleased to have pursued the examination further, but for want of time our report must here close.

All of which is respectfully submitted.

W. H. THORNTON,
JNO. GILL SHORTER,
W. S. PAULLIN,
} Committee.

Col. A McDonald, who had been selected to deliver an address before the Society upon agriculture, performed the duty in an able and interesting manner. The question selected at the last meeting, for discussion, viz: What benefit arises from agricultural societies? was discussed by H. Hemphill, Col. John G. Shorter and the Rev. Charles Evans.

Col. McDonald offered the following resolution:

Resolved, That in the death of William Beauchamp, Esq., the Barbour County Agricultural Society, has lost one of its earliest, most active and useful members, and the community at large one of its most worthy citizens.

On motion of Mr. Thos. Flournoy, a Committee of three were appointed by the Chair, consisting of Messrs. Tho's. Flournoy, Abney and J. G. Shorter, to make arrangements for a public dinner, to be given by the society on the fourth of July next, and to select a suitable individual to deliver an address on that day.

On motion of Benj. Gardner, Esq., the proceedings, with the address of Col. McDonald, were ordered to be published in the Southern Shield.

Reports of Committees appointed to ascertain and report the increase, diminution, &c., of the various crops of the farmers of Barbour county, report that they have examined twenty-two farms, which have in cultivation 2460 acres of cotton, 2976 acres of corn, 384 acres of potatoes, 270 acres of small grain, 53 acres of rice; and they find upon the farms above alluded to, an increase of the provision crop of 962 acres, about that of last year, and that there is a reduction of 400 acres in the cotton crop; they report that more attention is paid to the raising of stock, &c.

On motion, the Society adjourned to 4th July next.

H. HEMPHILL, Sec'y.

Agricultural Meeting in Warren County.

At a meeting of the citizens of Warren county, held at Warrenton on the 3d June, pursuant to a previous adjournment, John Harris, Esq., was called to the chair, and Joseph W. Thomas, Esq., requested to act as Secretary. On motion, the proceedings of a previous meeting were read, when the report of the committee appointed at a previous meeting to draft a constitution was called for and submitted through their chairman, G. V. Neal, Esq.

On motion of G. V. Neal, Esq,

Resolved, That the constitution, as reported by the Committe, be taken up for adoption by sections.

Which was unanimously consented to and adopted.

On motion, the Society went into an election of officers for the ensuing year, when it appeared that the following gentlemen were elected, viz:—JOHN HARRIS, President; G. W. Hardeway, Samuel Hall, sen., Sterling Evans, Vice-Presidents; John H. Roberts, jr., Secretary and Treasurer.

On motion of S. W. Smith, Esq.,

Resolved, That the Chair appoint a commit-

tee of three to draft by-laws, (for the further government of the Society,) to be reported at next meeting.

A door for members being opened, something like 50 immediately signed the constitution.

Adjourned to meet first Tuesday in July next.

JOHN HARRIS, President.

JOSEPH W. THOMAS, Secretary, *pro tem.*

Cotton Seed Oil.

From Ellsworth's Report for 1844.

[The following account of cotton-seed oil, &c., from J. Hamilton Cooper, esq., of Georgia, will be read with interest, as it shows the use which may yet be made of an article produced in large quantities, and before comparatively useless. A gentleman at the North is already making inquiries on this subject, which may lead to his embarking in this enterprise. It is not improbable, therefore, that cotton-planters may rejoice to find an article of so little value hitherto may be converted into an important article of domestic and foreign use. It was received too late for reference in the report.]

The seed of the *Sea-island* or *long-staple* cotton weighs about 40 lbs. to the bushel. As it is less coated with fibre, the yield of oil to the bushel will be considerably greater than that of the upland; but I am unable to say what it is. As the two kinds are only varieties of the same plant, it is presumed that there is no difference in the oil from the two.

Practically considered, the Sea-island cotton seed may be put out of the quesiion, from its limited production, and the value set on it by planters as a manure.

From the experiments made on a large scale at Natchez, the oil from upland cotton seed was found, when well refined, to burn as well as spermaceti; it made also an excellent paint oil. There was, however, much difficulty in refining it, and so much waste in accomplishing it as to render the manufacture unprofitable. The process employed were such as were then used in the Netherlands, France, and in America; but none of them was satisfactory. There is every reason to expect that the great improvements and discoveries now making in organic chemistry will soon supply a satisfactory process of refinement.

As there are 30 bushels of seed to every bale of cotton, each bale will yield at least 15 gallons of crude oil, and 360 lbs. of oil cake. If the oil can be made to be worth 50 cents per gallon, and the cake be sold only for 1 cent, an increase of $10 at least per bale will be given, which in 2,000,000 of bales will be $20,000,000.

Through the greater part of the western country, the seed is absolutely thrown away, as the lands are too rich to be manured. The oil-cake from cotton seed has been extensively used by me as feed for horses, cattle, and sheep, and was found to be excellent. It may be used with equal advantage with *rape-cake* for food or manure.

Upland or Sea-Island cotton seed may be obtained from any of the factors in Charleston or Savannah.

No difficulty exists in hulling, tempering or expressing the oil. The huller of *Follet & Smith* of Petersburg, Virginia, accomplishes the first very effectually, at the rate of a bushel of kernels in four or five minutes; and the machinery employed in French Flanders for rape-seed, &c., answers perfectly for cotton seed.

The present low prices of cotton will present a sufficient inducement to planters to save and sell the seed at reasonable priees; and it is believed that, if a cheap and effective mode of refining the oil can be discovered, this branch of manufacture will become one of very high value to the country.

J. HAMILTON COOPER, *near Darien, Ga.*

Memoranda of experiments made in January, 1836, at Natchez, to ascertain the relative quantities of crude oil, cake, &c., from the seed of the short staple or upland cotton.

A.—200 grains (by weight) of seed of good quality, well dried in the sun, opened by hand, and the kernels carefully separated from the hulls and fibre, gave of

Kernels	115½ grains,	being 57¾	per cent.
Hulls and fibre	84½ "	" 42¼	"
	200	100	

B.—The same seed, after being well sun-dried, were heated on a shovel over the fire, until they became crisp. They lost 2½ per cent. in weight.

C.—One bushel (even measure) of seed, heated during eight minutes in a drying kiln, was hulled by Follet's huller, and gave

Kernels	14½ lbs., or	54½	per cent.
Hulls and fibre	12¼ "	45¾	"
	26¾ lbs. weigbt of 1 bushel of seed, *even* or *struck* measure.		

D.—One bushel (heaped measure) kiln dried gave

Kernels	16½ lbs., or	54.17	per cent.
Hulls and fibre	13¾ "	45.83	"
	30 lbs. weight of 1 bushel of seed heaped measure.		

E.—Ten bushels of kiln dried seed slightly heaped weighed.....301 lbs.
When hulled, tbey yielded 9½ busheis of hulls, &c., weighing.....117 lbs.
And 5 bushels of kernels, weighing.....184 lbs.
Which 5 bushels of kernels when kneaded into a paste under the stones, with 2 quarts of water, gave 3 bushels 18 quarts of tempered *meal*, which weighed.....198 lbs.
or 58⅜ lbs. per bushel.

F.—The average weight of a bushel of tempered meal is..... 61 lbs.
Deduct for water..... 3 lbs.
Leaves the weight of the kernel..... 58 lbs.

G.—One gallon of crude oil from the press weighed 7 lbs. 6 oz.

H.—One bushel of well-tempered meal weighing 61 lbs. was pressed, and the cake retempered and repressed: it gave

1st pressing	6½	quarts of crude oil.
2d pressing	2¾ "	"
	9 1-10	

Weight of the bushel of meal.....61 lbs.
Weight of 9 1-10 quarts, at 7 lbs. 6 oz. per gallon, (G).....16¾ lbs.
Leaves weight of the *cake*.....44¼

Results.

One bushel of seed weighing 30 lbs gives 16 lbs. of kernel, which, when tempered and twice pressed, yields from 2¼ quarts to 2 7-10 quarts of crude oil, and 12¼ lbs. of cake.

How to Raise Turkeys.

The attention of our readers has been repeatedly called to the subject of raising poultry—in the vicinity of our large cities, perhaps no stock is so profitable. Some good practical hints may be taken from the following, which the editor of the New Jersey Journal gives as the result of considerable experience of his own. The young turkey is proverbially a tender chick, and it is a nice matter to know how to manage him properly.

We believe it is common among farmers to say that a turkey's head costs twice as much as its body is worth when fattened. This we do not believe to be true, if he is properly managed; but on the contrary, we believe that nothing can be raised and turned to so great a profit. But turkeys must have care, especially when young; but this care will not entrench on the business of the farmer, as it may be done by females or the younger branches of the family—and besides, the little damage they may do to grass or other things, must not be magnified tenfold, as is usually the case. But by proper attention they will do no damage at all.

Before giving our rules to be observed in raising turkeys, let us draw a comparison. There are few farmers but can raise 100 turkeys—these 100 turkeys will weigh, when fattened, in December, upon an average, seven and a half pounds each, full dressed. We say *full dressed*, for it is the practice in some places to divest the turkey of nothing but its head and feathers, and then take it to market. A practice as uncivilized as it is disgusting. These hundred turkeys then will weigh 750 lbs., which in market are equal to 1,500 lbs. of pork. But if the male turkeys are kept until February or March, they will not only increase in weight, twice the amount of their feed, but the price in market will be much higher.

We will now give the rules to be observed in raising and fattening them, founded wholly on our experience. Turkeys intended for breeders, must be kept well during the winter. If put in good condition, however, in December, it takes but little feed to keep them so. Their nests for laying must be made with hay or oat straw, under cover, and be well protected from the weather, and from vermin. When incubation commences, the turkey must not be disturbed, and if she does not come from her nest for food and water, she must have both placed by her on her nest. When the young turkeys are hatched, they may be allowed to remain one day on the nest, or if removed, let them be sheltered in a warm place, and plenty of straw for them to set upon, for they are now extremely liable to take cold. The second day feed them with curds, or warm clabbered milk mixed with a little Indian or barley meal. They must be kept up and fed in this way for two or three days, and longer if the weather should be cold or rainy, but as soon as a warm and pleasant day comes, let them out at nine or ten o'clock, and shut them up at four; and this practice of letting them out and shutting up *must* be followed for five or six weeks, and on no account let them get wet. When a young turkey begins to droop, there is but little hope for it. There is no danger of keeping them too warm. When they are five or six weeks old, put a little grease on their heads to preserve them from lice.

At the age of six or eight weeks the turkey is more hardy, but still should not be exposed to rains or the damp nights, for a few weeks longer. If the farmer has a plot of grass let him enclose a yard with a high fence, and crop the wings of the old turkeys, and continue to feed them with clabbered milk, and whatever else he pleases that comes from the kitchen, such as broken bread, potatoes, and the like. If he has a clover field, as soon as it is mown, let them run on it, and they will live on young clover. And as soon as the crops are off the ground, say in August or September, let them range on the farm; but see to it, that they come to their roosting place at night, and have water.

In December the turkeys will be large enough to fatten, and for this purpose select as many as you please, and shut them up—next take to the mill, a few bushels of *ears* of Indian corn, and have it ground—then boil potatoes, and mix the meal with the scalding water and potatoes in a tub, say in the proportion of one bushel of potatoes to one peck or more of meal, and stir them well together, then let it cool, but give it to the turkeys as warm as they will bear it, and as much as they will eat, and in two weeks and a half, they will be fat enough for market, and for an alderman's dinner.

We do not take this from books, but from several years' experience. We kept an exact account of the expense of raising and fattening a flock, and at the rate of ten cents a pound full dressed, we received $72, while our cost exclusive of sour milk, was less than $10. If any farmer does not wish to be at the *special* trouble of raising them, but should have a small flock to fatten, that have lived "in spite of wind and weather," let him adopt our rules of fattening, and he will "save much corn." On a large farm, and with a large yard and a butter dairy with proper attention we believe it may be mad, a leading business to great profit.—*Far. Cab.*

GATES FOR BARS.—There are few farmers so destitute of mechanical skill, as to be unable to make a substantial gate. This is a convenient, secure, time-saving, labor-saving, and we may add, *temper*-saving fixture. We know of no merit which bars have to recommend them in preference to the gate, and the substitution of the latter for the former, is always considered an improvement on a farm, as a good firm wall is in place of a flimsy fence.

Do not, if possible, depend on your neighbors for the *tools* required for such work as the making of a gate. Purchase them—and then you will not be liable to be interrupted in your work by a summons to return them at the moment, as you are in case of borrowed tools, and have to wait till the owner has done with them, before you can go on again—and then, perhaps, resume your work only to be again interrupted

by another call for the tools. This is vexatious both to borrower and lender, and not unfrequently engenders ill feeling on the part of one or both. Be as independent of borrowing as you can—but we do *not* add, *refuse to lend.*

Progress of English Agriculture.

Farmers are finding out that it is necessary for them, with a view to their own interests, to take a very different course from that which was followed by their grandfathers. In these days, no man is allowed to stand still. Improvement must go on. And I see throughout the country, in every part of it, gratifying proofs that improvement is going on, as actively in the agricultural as in the manufacturing districts and operations of the country. Even within the last four or five years, I see strides which, small as they may be compared with what might be done, are gigantic when compared with what was done before. I think it is not more than four or five years ago that, at a meeting of the Royal Agricultural Society of England, I first noticed, as a novelty of a singular character, a new manure, known as guano, and recommended to the agriculturists of England. If I am not misinformed, from the port of Liverpool alone there have gone out, within this single year, no less than 150 vessels, chartered expressly for the purpose of importing this then unknown manure for the improvement of the agriculture of the country. Everywhere I see old and useless fences disappearing, fields enlarging, improved modes of cultivation adopted; and I see going on with immense rapidity that which, I must again and again impress upon you who are connected with the land, is the basis of all improvement—deep thorough drainage of the land; and not here alone, but throughout all England, I see most remarkably, as indeed any one may do, even though whirled through the country at the railway speed with which we are now carried, what an extent of improvement has been effected in this respect. Every one is struck with the appearance of preparation for the future exertions, which are, at the same time, the token of well-deserved success.—*Lord Stanley at the Liverpool Agricultural Association.*

The Rat-Tail Geranium.—Speaking of plants, let us ask our friend if he ever heard of the celebrated "Rat-tail Geranium," which was first brought to public notice by a famous beau and courtier at Washington, some years since? It seems that he had a passion for Geraniums; and on one occasion he was informed by a friend ("beshrew him for a mad wag!") that if he desired to enrich his collection of plants with one not to be had elsewhere, and which had just been imported from the Niger, to lose not a moment in securing it. This was sufficient. Away he posted, and for a pretty penny became proprietor of the only Rat-tail Geranium in America. Placing it under his arm, he repaired to the residence of the lady of one of the high dignitaries of the Federal city. Placing it carefully upon the window-sill of the drawing-room, and as carefully adjusting the stem, which, he said, in consequence of a long voyage had become a little dry and lost its foliage; and giving especial directions to have it exposed to the sun, kept well watered, and taken in at night he made his congee and departed. On the third day it began to send forth its fragrance; each succeeding day it increased, but showed no signs of budding. On the sixth day, curiosity was on tip-toe to ascertain, by actual examination, the structure of a plant so redolent of a very remarkable perfume, and yet so withered and stiff, as was the stem of the "Rat-tail Niger Geranium." On removing the earth, and following the stem downward, lo! there lay the remains of an enormous rat, with his tail tied neatly up to a stick!—*Western Farmer and Gardener.*

☞Quite a stir has been created at Lowell by the introduction of a new cotton spinning frame which has just been put into operation there. It is said to require but *one half the power*, and will make *more yarn* and of more *even twist* at about *two-thirds the expense* of other kinds of frames in use.

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., AUGUST, 1845. No. 8.

LECTURE OF PROF. JOHNSTON.

We extract, says the Tennessee Agriculturist, the following Lecture delivered by Professor Johnston, before the Parish Schoolmasters of Scotland, from the Edinburgh (Scotland) Witness, of September 25th, detailing many valuable improvements that ought to be of the first moment in the old country. We hope to see the day speedily arrive when Agriculture in Schools, will be taught in every quarter of our land, and the generations that are to follow, benefitted and improved.

AGRICULTURAL INSTRUCTION IN SCHOOLS.

At the request of a number of parochial schoolmasters, Professor Johnston gave a lecture on Friday afternoon, in the High School Hall, on the introduction of agricultural instruction into elementary schools in Scotland. There was a very full attendance of schoolmasters and others interested in the matter. Mr. Gunn of the High School having been called to the chair,

Professor Johnston rose and said, that he should not have presumed to have appeared before them (the parish schoolmasters,) in reference to so important a subject as agricultural education had he not been requested to do so by various parties---by members of their own body and others. He had communications from various quarters on the subject, and had also had transmitted to him a memorial addressed to the Lord Justice-General from a parish schoolmaster, expressing a desire on the part of himself and others of the body, to introduce, among the various branches of education taught in their schools, some instruction in the principles and [illegible] agriculture. Besides, he had been encouraged [illegible] bring the matter before them, because of the result of a meeting lately held in Glasgow for the purpose of considering whether it was possible to introduce into elementary schools instruction in the elements of chemistry as applied to agriculture, and that without interfering with the ordinary course of study in these schools. He had previously had some doubts on the subject; but after hearing some boys, from the Irish National Schools, who were brought to Glasgow for the purpose, examined, all his scruples had been removed; and being himself satisfied, he now appeared before the present meeting for the purpose of stating his views of the matter. He was encouraged also, from what he had since observed in various parts of the country; for he found that there was a general desire on the part of the agriculturists that their children should receive that sort of education of which they themselves were deficient, in order that they might improve their condition in life by cultivating the land to more advantage than had hitherto been done. In what he should take the liberty of saying, he begged to be distinctly understood, that he spoke only his own views---he committed no other parties to any points in which they might think proper to differ from him. He did not appear before them as representing the Agricultural Chemistry Association, but simply as an individual, and in compliance with their own request—a request he had been most willing to meet. It was important that such instruction as he alluded to should be given, because the population of the country was ahead of the present productive powers of the land—because the land did not now produce enough of corn for the people--and because the land of the country could easily be made to maintain a much larger population, and, in doing so, give more profit to the farmer. Scotland was as much advanced in the science of agriculture as any other country; but in every other country it had been demonstrated that the best cultivated districts might be improved by the application of chemistry to the land. The general persuasion of its importance was such, that Agricultural Chemistry Colleges had been established at Petersburg, at Moscow, in the West Indies, in England, and also in Ireland. In fact, agricultural schools were springing up everywhere, in a way adapted to the circumstances of each country. He was clearly of opinion, that it was of especial importance to introduce agricultural instruction into our parish and other elementary schools. Some farmers who were possessed of wealth were enabled to send their sons to other than the parish schools to receive their education; but it was otherwise with the small farmers in many districts, especially in Ayrshire, whose sons had no other education than they received at these schools. He need not tell them how difficult it was for the farmer to acquire new and additional information when engaged in the cultivation of his farm; therefore it was of great importance, if the land was to be made more productive, that that kind of knowledge which would conduce to accomplish so desirable an end, should be acquired while at school, by those who were to succeed their fathers in the cultivation of the soil. Besides the farmers' sons, there were the sons of the laboring class, from whence the grieves all rose; and when they considered how much the prosperity of the country depended on the knowledge of the laborers, the meeting would see how important it was that the sons of the laboring classes should acquire that knowledge before they left school, thereby giving them the means of raising and bettering their future condition in life. His audience were probably aware, that an idea prevailed, that by giving to the laboring class a portion of land to cultivate, their moral condition as well as their animal comforts would be greatly increased; therefore they would see how important it was that those classes should be properly educated, not only to promote the improvement of the country generally, but that they might be prepared for the cultivation of allotments, should they obtain them, and be fitted to become more useful members of society than they had hitherto been. He came now to the consideration of what should be taught. Agriculture divided itself strictly into three branches,---1st, the culture and improvement of the soil; 2d, the rearing and improvement of stock; and 3d, the use and improvement of agricultural implements. The force of agricultural societies had been mainly directed to the second branch, consequently the improvement of stock had gone ahead of the improvement of the land; and this in face of the fact, that the land was the more important of the two, as being the feeder not only of the stock, but of the people also. Indeed, he held in his hand a letter from a most intelligent farmer, who stated that the stock was too good for the land. And as the cultivation of the land was of the greatest importance, the other two branches being subsidiary to it, the force of the schoolmasters would be most usefully, as it would be most easily, directed to teaching in regard to the culture and improvement of the soil. Now, their teaching might be of two kinds—theoretical, or practical, or both. He would come to the consideration of both. He thought that in elementary schools they might easily inculcate and impress on the minds of the youth under their care, the principles upon which the culture of the soil ought to be based. Of the sciences on which these principles depend, chemistry was the most important; and it was necessary, therefore, before they could teach the young mind, that they should give a knowledge of so much elementary chemistry as to make him understand the words used by the chemists. It was not enough that he should know such names as soda and potash,—he should also know the difference between them. They must not teach any one science for its own sake, but as an important branch of national industry.—They must not be led away by their attachment to one branch, such as chemistry, so as to give too much of it, but only so much as was necessary to explain the principles upon which that branch of industry was based, in order that the pupil might understand and comprehend the new words which they were obliged to make use of. They were to make their pupils, not chemists, not botanists, but scientific farmers; for in that the public were interested and would support them. [Here Professor Johnston referred his audience to a catechism which he had drawn up at the request of the schoolmasters of Ayrshire.] As to the experiments they would find it necessary to make, they were few and very simple. For instance, here was the carbonate of soda in one glass vessel, and the carbonate of lime in another. Take and pour spirits of salt on them, and they would observe carbonic acid gas arise, which extinguished a lighted taper when put into the vessel. They would also perceive that the smoke of the extinguished taper floated on the top of the gas, thereby showing how much was in the vessel. This gas, they were aware, performed most important functions; but it was not necessary to give the boy more information than was requisite to fix in his mind the name and property of the gas. Then as to phosphoric acid—here was a piece of phosphorus, which they would observe, when he burned it under a glass, sent up white flames; all they had to do, therefore, was to tell the boy that those white flames were phosphoric acid; that the same was in his bones and in the food which he eats—and he would then easily remember what phosphoric acid was. If they did not happen to have phosphorus by them, they might use lucifer matches, which are easily procured, which on friction being applied to them send up the same sort of white vapor as did the phosphorus which they had just seen burned. They could also connect carbonic acid with the daily life of the pupil, by telling him that what was produced when charcoal was burned was what he breathed. He would then go and tell his father that this same substance which he throws off from his lungs was what the leaves of plants sucked in; that plants took it from starch, and that animals eat the starch to form it. After making an experiment to show that liquid manure was an important substance if applied to plants, as it greatly promoted their growth, the Professor then went on to say that the more simple the teacher could make his experiments the better—they should teach no more

philosophy than was absolutely necessary; but at the same time it must be strictly correct. He would advise them to confine themselves to facts—not to announce the principles. He would also press upon them, in endeavoring to fix facts on the boy's mind, to call to aid all his senses—his sense of sight, for instance. Then as to smell, ammonia might be used; and for taste, common salt, alum, and soda, which were perfectly harmless. As to touch, sal-ammoniac would be of use. They would observe that the little piece which he had just broken off, bent; and he knew of no other substance which a boy was likely to meet with that would bend in like manner. The Professor then directed attention to a set of tables which he recommended for the use of elementary schools—one of them, to which he specially called the observation of the meeting, was an exposition of the ash of the different kinds of grain, namely, potash, soda, lime, magnesia, oxide of iron, oxide of magnese, phosphoric acid, sulphuric acid, silicia, and chlorine. He remarked that such a table as this would tend much to fix the words used by chemists in the memory of the pupils; and also to impress principles upon their mind: as, for instance, that in the ash of all the different kinds of grain, there was more phosphoric acid than any other substance. As to the means of information for themselves, it was a great convenience to him, in bringing the subject forward, both here and elsewhere, that he could offer them his own books; a few months ago, and he could not have told them where the knowledge they required could be obtained. As to the expense of making the experiments, it would not amount to more than five shillings a-year, as the materials could be procured at a very cheap rate. With regard to the apparatus, all that was necessary could be got for thirty shillings from Messrs. Griffin of Glasgow, who had, at his request, prepared a set of apparatus. Then, as to the time it would occupy to teach the science, why, that was a point on which some misapprehension might readily arise. The boys who attended school generally did so for three or four years. Now all that he asked was one hour a week—that was enough to learn all that was necessary to be taught on the subject; but if they could give him two hours he should like it better, as then there would be time to spare. The children also would learn much without teaching, from seeing the tables he had alluded to, and also from experiments. He did not wish that this one hour a-week should interfere with the usual course of instruction, although it might not necessarily be new or additional to what was now given to teaching. In fact, he did not wish any of them to teach in one particular way or another; he left that to themselves, merely taking the liberty of giving his opinion in the matter. As to the practical teaching of the science, that could be done in various ways. For instance, they might on a Saturday afternoon go with the boys to a farm in the neighborhood, and describe the operations of the farmer. After telling them all about the rotation of crops—that a green crop followed after grain, and so forth, the teacher might then say, let us go now and see how the farmer works. This, he thought, might be of great benefit to the scholars. As to school farms, the system of attaching pieces of land to schools had been adopted in reference to the Irish National Schools; it was also done in the schools which had been established in England; and it had been proposed to adopt a similar practice here. But this he did not hold to be indispensable. If he were asked the question, should the schoolmasters have a five acre glebe, he would say that in no case of a parish school did he contemplate that the master should work so many hours a day in his farm, and superintend the labor of the boys. But he had no crotchet in his head on this point—his mind was not made up on the subject; and although he might afterwards recommend it, at present his opinion, if asked, was, "as a general rule no, at least at first." But if they differed from him, he left them to do as they liked—making only these two conditions, viz., that they did not lower themselves in station—that they neglected none of the other important branches of education. There were two objections to the proposal. In the first place, there was a jealousy on the part of the schoolmasters themselves that it would lower them in public estimation to cultivate land, at the same time that they were engaged in the cultivation of the youthful mind. Then there was a jealousy on the part of those interested in the proper teaching of the scholars, lest the master, finding it profitable to cultivate, should take more than he could properly cultivate, and thus neglect other and more important matters. But no general rule could be laid down in this respect, as all the schools were differently circumstanced. The same mode would not suit for all, as the same necessity did not exist in every case for having pieces of land attached to the parish schools. As an inducement to them to pursue a course of agricultural education, he might remark, that they would have the satisfaction of contributing towards a great national good, and they would also maintain the parish schools in that position and pre eminence which it was desirable they should ever be in, and thus neutralise rivalry. The Government of the country took an interest in the subject—they had shown that they did so, by declaring themselves in favor of a course of agricultural education, and establishing schools for that purpose. Now, the parochial schoolmasters, many of whom he now addressed, were at present, through their friends, making an application to parliament for an increase to their allowance, which was allowed on all hands to be too small; and he held in his hand a letter from a gentleman who took a great interest in the matter, which stated that if the schoolmasters showed an interest to promote the fundamental welfare of the country, as, for instance, the improvement of agriculture, it would have great weight with Parliament. Another point was, that as individuals they would have an opportunity of bringing themselves into notice, and new means of rising presented to them. It would increase their consideration in the locality where they resided. For instance, a schoolmaster might go to a farmer and talk to him about Latin, which he would not care about, as he did not understand it; but if he could hold the plow, then he would think him a better man. As an illustration of this feeling, he might mention what the schoolmaster of Eyemouth had said, "If I could teach fishing, the parents would take more interest in the school." (Laughter.) They would, he repeated, render themselves of more importance in the district where they resided, and be thought more of by the farmers and others with whom they came in contact. They might find indifference, and might meet with opposition; but their hands might be strengthened by the establishment of clubs; and he would therefore recommend them to meet occasionally and consult with one another regarding the mode of teaching; and by doing so, he had no doubt they would overcome many local difficulties. The way to gain over the old farmers to their views—to remove their prejudices—was not by opposing and railing at them, but by becoming in appearance their pupils; not by propounding hastily formed and positive opinions, but by calmly and dispassionately conversing with them on the subject. The subject, he might add, was interesting to all parties in Parliament. The Field Gardens Bill, was an evidence of that on the part of one section of the House, and was not unfavored by Government. Another section proposed to join with it an Agricultural School Bill. In conclusion, the Professor said that if twenty of the gentlemen present would like to hear an address on the science itself, in order that they might have an opportunity of understanding some of its beauties, he would be happy to meet them next forenoon in the same place.

The offer of Prof. Johnston was at once accepted, and a Committee named to make the necessary arrangements.

The meeting then separated.

GOV. HAMMOND'S REPORT.

From the South Western Farmer.

We give at the conclusion of this notice, the Report of a Committee of which our friend, J. H. Hammond, was chairman. We congratulate him on the knowledge of farming that he displays. We see how readily the educated and intelligent can learn the business of farming. But a short time since, our old school-mate was up to his eyes in politics—he now retires to the field—there to live a quiet, peaceable life. We rejoice at it, and can but repeat the remark we made to him, before he was elected Governor—"You are wrong—you have no business in that sphere—seek your ease and peace—it suits you better and will give you satisfaction." His answer was then, as his works answer now: "I will do so as early as the force of circumstances will permit"—or to this purport were both.

We again congratulate him, and also our country, in the success of our friend—we also press on all agriculturists any articles from the pen of Hammond; he will, we feel assured, give all matters that he writes on, his minute and particular attention. We have known him from both of our boyhoods, and know him to be talented and observing, and more than all, when he does apply himself, it is an application deserving and insuring success.

As we are his senior in planting the cotton, especially in personal attention to it, we beg to give him a hint or two. We may err in our notions; and why we say so, is, that we differ materially from so large a number of farmers. We think that very early planting is disadvantageous; and to define early planting, we think the last week in March is early enough at any time, even for this year, when, it will be borne in mind, the fruit trees were quite green at that time; to plant as early as the 15th or 20th of March is "very early." We generally judge it to be time to plant corn when the "leaf of the oak is as large as the squirrel's ear," many of our planters have planted cotton as early. We think cotton planted from the 1st to the 10th of April is early enough for old land, and have known by several crops that the later planting, say 10th, was considerably better than the early—we know this not only by our own weights and measures, but also by others.

We would make an exception to early planting. New ground and rich fresh land, from such a tendency to make weed, that it is necessary to plant as early as a stand can be had—so all think; we would not object, but think that judicious culture would make a different result. We would act precisely as with the tree that produced wood instead of fruit—amputate the roots. We think that if the land has been broken up very early, and left to be consolidated by rains, then plant about the 5th to the 10th of April, thinned out as early as it was up, cultivated deep and late, that the stalks would set the fruit and ripen in time. Do we not thus with fruit trees, Irish potatoe and sweet potatoe—the latter too, by either cutting off tops, or feeding with calves? And why not a similar practice with the cotton plant?

The cotton plant is a very tender plant if treated as it was some ten or fifteen years since—some three to six bushel of seed sown per acre, and not thinned out until the third leaf had appeared—it has been raised in a hot bed, and no wonder it is tender; but if sown thinly, and then thinned out to single stalks, we think it a hardy plant. There is no use in trying the hardihood of the plant. It is unlike corn—it has a tap root, grows in dry weather, and unless the land has not been properly prepared, or remarkably dry, it will improve by hot or dry weather—but corn having superficial roots, should be planted early as possible, that it may ripen before drought sets in. If cotton will make 1000 lbs. per acre when planted late in May there can be no fears to plant 10th April. The farmer can place his land in excellent order—have his corn cleaned handsomely, and when cotton is up, he can push it to the utmost. We request our friend H. to

plant one acre of cotton, even now, after his seeing this, on a piece of well plowed land, in he same field that he has now even scraped over; just open out furrows where the cotton now stands, which will destroy the cotton that has been scraped. Our impression is, that the difference will be very slight, and if adopted generally would give considerable time to manure, plow and improve, instead of giving cotton the additional working necessary. The land that we have known planted late, would not in average seasons make anything like one-third more, by early planting, and if the extra labor was applied to improving it, we doubt, if it would yield as much. Understand, we do not advocate either late or early planting—that is, after the 25th of April or before 1st—and only wish to show there is not so vast a difference between planting 1st April and 1st May. What would be the gain to any farm by the extra month's work? P.

REPORT OF THE COMMITTEE OF THE BARNWELL AGRICULTURAL SOCIETY ON THE CULTURE OF COTTON.

The ground cannot be too well prepared for Cotton.—If it had rested one year it should be broken flush, as early in the previous fall as possible, and headed just before planting. If it has rested two years or been planted the preceding year, let it be listed as early as it can be done, and two furrows thrown upon the list. Immediately upon planting let two more furrows be thrown up, and balk broken out completely. The common method of running three furrows, and planting on it, throws the winter's portion of the crop-work upon the laborer, during crop time, and is inexcusable, unless heavy clearings are absolutely required. The reason for not listing after one year's rest, is, that the vegetable matter will be too abundant and too coarse to form a substratum to receive the tap-root.

Cotton should be planted early—It may increase the difficulty of getting a stand, and give the plant, for a long time, a puny appearance, but every stalk of Cotton planted in March, or first week in April, that survives, may be readily distinguished, in any field that has been replanted later. It bears more, and earlier, and stands all the vicissitudes of June, July and August, better. There are several methods of planting. Your committee recommend planting in spots, regularly measured by the dibble. It is somewhat tedious, though less so than is generally supposed, and certainly does not take as much time as both to drill and chop out; nor is time so valuable at that period, as when the latter operation is required, while a better and more regular stand may be secured. There is no land, or but little, in our district, in which cotton rows should be over three feet apart, or the cotton further than fourteen inches in the drill, one plant in a place. To make a large crop there must be an abundant supply of stalks. When the weather is too wet to plant, time may be often saved by dropping the seed, but not covering until the ground is dryer. If, however, it cannot be covered in three or four days, it is time lost, for it must be re-planted. Always cover lightly, under any circumstances. And always plant on something of a bed, in any land. It keeps cotton dryer, and affords more air when it is young. It enables you to get at it in working. By increasing the surface, it absorbs more moisture, if it is too dry; and gives out more if it is too wet, and in both cases gives you the advantage of a vertical sun on the tap-root, which hastens the maturity of the bolls—a vast desideratum in our climate. On this account the bed can hardly be drawn too high at the last hoeing, in any season.

In cultivating Cotton, whether with the plow or hoe, the chief object is to keep down the grass, which is its greatest antagonist, bringing all, or almost all other evils in its train. It is not so essential, in the opinion of your committee, to keep the ground stirred, as is generally supposed, and by no means requisite to stir it deep; at all events not to our light soil. If it be well prepared, deep plowing is not only unnecessary for any of our crops, but often highly injurious to them, while it rapidly exhausts the land, by turning it up fresh, under a burning sun. Much unnecessary pains is usually taken, and time lost, to work the plant in a particular way, under the supposition that it is a peculiarly delicate one. If it survives its infancy, few plants are hardier. It is often found to reach maturity in the alleys, where the mules walk with the plows following and the laborer tramps backwards and forwards. Sometimes it will bear fruit in turnrows used frequently for wagons, while it really seems to derive benefit from being bitten down almost to the ground by the animals, it will bear almost any usage better than it will that mortal enemy—grass.

The most critical operation in working cotton *is thinning*. It should be done with great care, and if early, with the hand. In a dry year, it cannot be done too early after the plant is up. In a wet one, it may be profitably delayed, until it has begun to form or later even. On the experience, observation and judgment of the planter, in this matter, everything depends, as each year brings its own rules with it. Where circumstances are favorable early thinning is of course the best. Some planters always top their cotton. Others never do. Your committee are of spinion, that it seldom or never does harm to do so. But whether it is worth the trouble, is a doubtful question. Those who have no clearing, or other important employ for their hands, would lose nothing by devoting three or four days to this operation early in August. Those pressed for time might gain by omitting it.

Too much pains cannot be taken in preparing Cotton for market, for they are well remunerated by the additional price. The first thing to be attended to, is to have it gathered free of trash. With a little care wonders can be effected in this way; and hands with a short training, will pick almost, if not quite, as much without trash as with it. It should never be gathered when wet. And here it may not be out of place to remark, that one of the very best sanitory rules of a plantation is never to send out your hands to pick until the dew has nearly or quite disappeared. It saves time in the long run, as well as health and life. Cotton should never be ginned, until the seed are so dry as to crack between the teeth. If damp, it is preferable to dry it in the shade, as the sun extracts the oil and injures the staple. If, by accident, however, it gets wet, there is no alternative but to put it on the scaffold. It is of great importance to sort the cotton carefully, into several qualities, in ginning and packing, for by mixing all qualities together, the average of the price is certainly lowered. A few old hands or very young ones, breeding women, sucklers, and invalids, will earn excellent wages in a ginhouse at this occupation. Neat packing is of no small importance, in the sale of cotton, and no little taste may be displayed in making the packages. The advantage of square bags is universally known and the committee are astonished that any other should ever be made now.

Every kind of manure is valuable for cotton.—Every kind of compost, green crops turned in, cotton seed and even naked leaves listed and left to rot, improves this crop. When planted on cotton seed, and sometimes on strong stable manure, it is more difficult to retain a stand, owing probably to the over stimulus of these strong manures. So, on leaves, unless well rotted, the cotton will long continue to die, in consequence of the leaves decaying away and exposing the root too much to sun and rain. These difficulties may be avoided, by a little pains, and by no means justify the opinion entertained by some, that cotton should never be planted on freshly manured land. The only question is the cost of the manure. A great deal may be made on every plantation, without much trouble or expense, by keeping the stables and stable yard, hog and cow pens, well supplied with leaves and straw. And also from pens of corncobs; sweepings from negro and fowl house yards and rank weeds that spring up about them collected together and left to rot. Whenever the business is carried further, and a regular force is detached to make manure at all seasons, and entirely left out from the crop, it becomes the owner to enter into a close calculation of the cost and profits. In many agricultural operations, such a course, the experience of all countries has proved to be profitable, but these operations partake rather more of the farming and gardening, than planting character, and whether the same method will do for the extensive planting of short staple cotton remains, in the opinion of your committee, yet to be tested. If anything like an average of past prices can be maintained, it is certain that more can be made by planting largely than by making manure as a crop. If, however, prices continue to fall, and the growing of cotton be confined to a few rich spots—those susceptible of high manuring—then our whole system must be changed, our crops must be curtailed, and staple-labor losing its past value, the comparative profit of a cotton and manure crop, will preponderate in favor of the latter. As a substitute for manuring on a large scale, resting and rotation of crops is resorted to. In our right level land, the practice of resting cannot be too highly recommended, and, by a judicious course, such as resting two and planting two, or at most three years, our lands may not only be kept up for ever, but absolutely improved. From rotation of crops but little is gained for cotton. After small grain, whether from the exhausting nature of that crop, on light lands, or because the stubble keeps the ground always rough and porous, cotton will not do well. After corn it is difficult to tend, as from our usual manner of cultivating corn, grass is always left in full possession of the field. It does best after cotton, or after a year's rest. Rest is the grand restorer, and the rotation chiefly required in the cultivation of cotton.

J. H. Hammond, Chairman.

CULTIVATION OF CELERY.

From Ellsworth's Report for 1841

New York, December 12, 1844.

Dear Sir: The cultivation and growth of celery, that most excellent and wholesome winter vegetable, requires the close attention of the gardener to bring it to perfection.

A practical gardener will soon learn the art; and for the benefit of those who have yet to learn it, I beg to hand you the result of my own experience for the last 25 years.

In this country, it is not necessary to sow the seed before the month of May, and then in the open ground, well manured with stable dung thoroughly cured, and not less than a year old. The color, whether white or red, is a matter of taste. I generally mix my seed, and thus have both species. The seed is slow of vegetation, but, if good, never fails to germinate. Whether the seed be sown broadcast or in drills, is a matter of no consequence; as the seed being very small, the plants are sure to shoot up thick. So soon as the sprouts have attained the height of an inch, they should be pricked out in a bed of rich mould, at the distance of about three inches each way from each other. You cannot have good strong stocky plants without pursuing this method. If left standing in the seedling-bed, they will grow spindling, weak, and consumptive. No more attention is required, excepting that of keeping the plants perfectly free from weeds, until August, when you will find the plants strong, healthy and vigorous.

Any time in this month, dig your trenches 18 inches deep and as many wide. For this purpose, I generally occupy the ground that has been used for early peas.

The quality of the celery, and chiefly its growth, depend entirely upon the next step. The trenches should be half filled with thoroughly cured stable manure. I have found the manure used for early hot-beds the best. It never fails of success. The increased fermentation of the manure, by the repeated waterings of the beds, the escape of the ammonia and noxious qualities of the manure, renders it sweet, and capable of imparting the mildest and richest

flavor to the plant. If fresh manure from the yard, of whatever kind, is used, the celery will invariably grow strong and rank, with as little delicacy of flavor as there is in the manure. With a garden fork of four tines, strike through the manure in the trench into the earth beneath, and bring it up fresh, carefully mixing it with the manure as you proceed from one end of the trench to the other. Attention to this point is indispensable to the growth of good celery.

The plants taken up should be trimmed about the crown, just at the top of the root; all the young suckers taken off, leaving the plant trim and neat, with all its main stalks. With a dibble, which should be as large as the handle of a spade, as the roots will now be of considerable size, begin at one end of the trench with your face towards the other, and set in a single row of plants in the middle of the trench, and not less than 6 inches asunder; water them well. No tetotaler loves water better than celery. It cannot have too much. The roots of this plant require more room than is generally allowed them, as any one may see when they are taken up for the table.

Earthing up the plants should be delayed until they have attained a good size; and then it requires care, especially the first time. I always get into the trench myself, and, holding the plant with all its stalks firmly in my left hand, with a short handled small hoe draw the earth up round the plant, without allowing it to come in between the stalks. When this is done, and the plants thus protected, you may, with a spade, strike off the edges of the trench, and partially fill it. As the plant grows, (as it now will, if well watered in dry weather, with great vigor) continue to earth up, and by the 1st of November the plants will be two feet above the level of the earth, and with a main stalk the size of a man's arm.

Sometimes, particularly if the season is dry, celery is liable to be attacked by a fly. In that case, you will see the tops of the celery turn brown and wither. The moment that symptom appears, no time is to be lost in calling in the doctor, for the whole crop is at stake. The cause of the disease is the sting of a fly upon the leaves of the celery. The egg is deposited between the integuments of the leaf, and soon hatches into a small white worm—sometimes visible on opening the leaf to the naked eye, always by the aid of a microscope. If not attended to, the disease gradually descends to the root, and the whole plant falls a sacrifice. Amputate every defective and diseased leaf; and early in the morning, whilst the dew is on, sift on to the whole of the plants fresh slaked lime. One such powdering is generally sufficient; but if not, give them another dose, and the first rain that falls will wash the plants clean, and you will probably see them fresh, green and stretching away towards maturity.

With regard to the mode of securing the crop for winter use, gentlemen have their fancies. I prefer leaving the plants in their original trenches, earthing up to the top of the plants, and covering with straw litter and boards, so as to protect them sufficiently from the frost, to be able to take them up as wanted; and this always fresh and sweet. I do not fancy disturbing the roots, and transplanting into narrow quarters.

Finally, any one in this country who wishes to have "first rate" celery must cultivate it himself. Common laborers are sure to spoil it. Professional gardeners are seldom found, and generally too expensive when they are.

Your ob't servant, JUNIUS SMITH.

Extract from a letter from Henry Smith, Esq., dated Astoria, New York, January 13, 1845.

Dear Sir: Agreeably to your request, I have measured some of the celery, taking a fair run of that which was taken up from the back garden: 1st root measured 29 inches in length, and diameter proportionally large; 2d root measured 29 inches in length, diameter in proportion; 3d root 29 inches in length, diameter also in proportion.

The celery is as fine as I ever had in quality; and I do not know that I ever saw much better even in Lancashire, where you know they are proverbial for fine celery. The parcel which we removed from the garden to the cellar, under the wing of the house, is all decaying very much as we expected it would; whilst the lot left standing in the garden, is beautiful and fresh.

HORTICULTURAL OUTLINE.

AN OUTLINE OF THE FIRST PRINCIPLES OF HORTICULTURE: By JOHN LINDLEY, F.R.S., &c., &c., Professor of Botany in the University of London, and Assistant Secretary of the Horticultural Society.—[CONTINUED.]

X. SAP.

260. The fluid matter which is absorbed either from the earth or from the air is called sap.

261. When it first enters a plant it consists of water holding certain principles, especially carbonic acid, in solution.

262. These principles chiefly consist of animal or vegetable matter in a state of decomposition, and are energetic in proportion to their solubility, or tendency to form carbonic acid by combining with the oxygen of the air.

263. Sap soon afterwards acquires the nature of mucilage or sugar, and subsequently becomes still further altered by the admixture of such soluble matter as it receives in passing in its route through the alburnum or newly formed woody tissue. (65.)

264. When it reaches the vicinity of the leaves it is attracted into them, and there having been exposed to light and air, is converted into the secretions peculiar to the species.

265. It finally, in its altered state, sinks down the bark, whence it is given off literally by the medullary rays, and is distributed through the system.

266. No solid matter whatever can be taken up by the roots; for this reason, metals, which in the state of oxydes are poisonous, are perfectly harmless in their metallic state, as mercury; and this is, no doubt, the cause why liquid manure, which contains all the soluble parts of manure in a fluid state, acts with so much more energy than stimulating substances in a solid state.

267. The cause of the motion of the sap is the attraction of the leaf-bud and leaves.

268. The leaf-buds called into growth by the combined action of the increasing temperature and light of spring, decompose their carbonic acid (279,) and attract fluid from the tissue immediately below them; the space so caused is filled up by fluid again attracted from below, and thus a motion gradually takes place in the sap from one extremity to the other.

269. Consequently the motion of the sap takes place first in the branches and last in the roots.

270. For this reason a branch of a plant subjected to a high temperature in winter, will grow while its stem is exposed to a very low temperature.

271. But growth under such circumstances will not long be maintained, unless the roots are secured from the reach of frost; for, if frozen they cannot act, and will, consequently, be unable to replace the sap of which the stem is emptied by the attraction of the buds converted into branches, and by the perspiration of the leaves. (XII.)

272. Whatever tends to inspissate the sap, such as a dry and heated atmosphere, or an interruption of its rapid flow, or a great decomposition of carbonic acid by full exposure to light, has the property of causing excessive vigor to be diminished, and flower buds to be produced.

273. While, on the other hand, whatever tends to dilute the sap, such as a damp atmosphere, a free and uninterrupted circulation, or a great accumulation of oxygen in consequence of the imperfect decomposition of carbonic acid, has the property of causing excessively rapid growth, and an exclusive production of leaf-buds.

274. Inspissated or accumulated sap is, therefore, a great cause of fertility.

275. And thin fluid, not being elaborated, is a great cause of sterility.

276. The conversion of sap into different kinds of secretion is effected by the combined action of *Air* (XI.), *Light* (XI.), *and Temperature.*

XI. AIR AND LIGHT.

277. When an embryo plant (242,) is formed within its integuments, it is usually colorless, or nearly so; but, as soon as it begins to grow, that part which approaches the light (the stem,) becomes colored, while the opposite extremity (the root) remains colorless.

278. The parts exposed to the air absorb oxygen at night, absorb carbonic acid and part with oxygen again in day-light; and thus in the daytime purify the air, and render it fit for the respiration of man.

279. The intensity of this latter phenomenon is in proportion to the intensity of solar light to which leaves are directly exposed.

280. Its cause is the decomposition of carbonic acid, the extrication of oxygen, and the acquisition by the plant of carbon in a solid state; from which, modified by the peculiar vital actions of species, color and secretions are supposed to result.

281. For it is found that the intensity of color and the quantity of secretions are in proportion to the exposure to light and air, as is shown by the deeper color of the upper side of leaves, &c.

282. And by the fact that if plants be grown in air from which light is excluded, neither color nor secretions are formed, as is exemplified in blanched vegetables; which, if even naturally poisonous, may, from want of exposure to light, become wholesome, as celery.

283. When any color appears in parts developed in the dark, it is generally caused by the absorption of such coloring matter as pre-existed in the root or other body from which the blanched shoot proceeds, as in some kinds of rhubarb when forced.

284. Or by the deposition of coloring matter formed by parts developed in light, as in the subterranean roots of beets, carrots, &c.

285. What is true of color is also true of flavor, which equally depends upon light for its existence; because flavor is produced by chemical alterations in the sap caused by exposure to light. (229.)

286. The same thing occurs in regard to nutritive matter, which in like manner is formed by the exposure of leaves to light. Thus the potatoe when forced in dark houses contains no more amylaceous matter than previously existed in the original tuber; but acquires it in abundance when placed in the light, and deposits it in proportion as it is influenced by light and air. Thus, also, if peaches are grown in wooden houses, at a distance from the light, they will form so little nutritive matter as to be unable to support a crop of fruit, the greater part of which will fall off. And for a similar reason, it is only the outside shoots of standard fruit trees that bear fruit. Considerations of this kind form in part the basis of pruning and training.

287. Light is the most powerful stimulus that can be employed to excite the vital actions of plants, and its energy is in proportion to its intensity; so that the direct rays of the sun will produce much more powerful effects than the diffused light of day.

288. Hence, if buds, that are very excitable are placed in a diffused light, their excitability will be checked.

289. And if buds that are very torpid are exposed to direct light, they will be stimulated into action.

290. So that what parts of a tree shall first begin to grow in the spring may be determined at the will of the cultivator.

291. This is the key to some important practices in forcing.

292. This should also cause attention to be paid to shading buds from the direct rays of the sun in particular cases: as in that of cuttings, whose buds, if too rapidly excited, might exhaust their only reservoir of sap, the stem, before new roots were formed to repair such loss.

293. As plants derive an essential part of their food from the air (280) by the action of light, it follows that in glass-houses those which admit the greatest portion of light are the best adapted for purposes of cultivation.

294. The proportion of opaque matter in the roof of a glass-house constructed of wood varies from ⅛ to 1-7—that of an iron house does not exceed 1-23.

295. Therefore iron-roofed houses are in this respect better suited for cultivation than wooden-roofed houses.

296. And it has been found by experiment, that light passes more freely through a curvilinear than through a plain roof, and through glass forming an acute angle with the horizon than through perpendicular glass, it follows that a curvilinear roof is best, and a plain roof with glass perpendicular sides the worst adapted to the purposes of the cultivator.

297. For the same reason common green glass is less fitted for glazing forcing-houses than white crown glass.

298. Poisonous gasses in very minute quantities act upon vegetation with great energy. A ten-thousandth part of sulphurous acid gas is quickly fatal to the life of plants; and hence the danger of flues heated by coal fires, and the impossibility of making many species grow in the vicinity of houses heated by coal fires, or in large towns. (*To be continued.*)

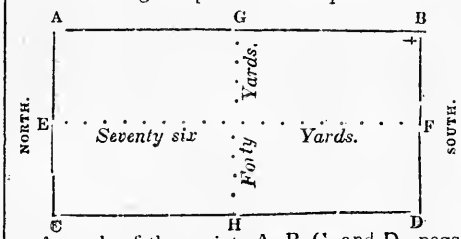
ELECTRICITY and AGRICULTURE.

The element which now promises to be turned to the increased uses of man in the most extraordinary way is electricity. Already we find communications made, and conversations sustained, between parties fifty miles apart, with nearly as much rapidity as could be performed by any system of symbols in the same room. By means of the electric telegraph London is brought into instantaneous proximity with Windsor, Southampton, and other places, and before long there is every reason to expect that communications may be made between all the important parts of the country in a few seconds. We have already seen some extraordinary examples of the effects of this rapid communication, not the least striking of which was the capture of the late unhappy man Tawell. On the other hand, we now hear of games of chess and whist being sustained and carried on at distances of fifty or sixty miles, as if the parties were all in the same room. Hitherto it has been thought that a man having the start for any object by railway was secure from pursuit, but now this new agent will arrest his progress or anticipate his arrival at any point with more ease than a man on the fleetest horse could overtake another on foot.

But of all the uses to which this new and marvellous agent has been applied, none promises such remarkable results as to agriculture. It is a principle when has been long admitted and understood, that electricity had a considerable effect on vegetation, but it has not been till now that any practical application of that aid has been attempted. Of late many experiments have been made, in a manner, too, which affords means of judging, not only the comparative result but comparative cost. And we are bound to say that they are such, that we look upon this new agent, as one likely, before long, to produce as great a revolution in agriculture as the inventions of the steam engine or the spinning jenny have done in manufactures.

We have before us the result of one experiment on a considerable scale, which, we think, cannot but prove highly interesting to our readers. It took place in the north of Scotland.

A portion of a field of barley, to which the electric application was made, produced last year at the rate of *thirteen quarters and a half* to the acre, while the surrounding land, similarly treated in other respects, produced the usual quantity of *five* to *six* quarters to the acre. The following is a detail of the very simple mode in which the electric fluid is collected and appl die o influence the land. A field is divided into oblong squares, 76 yards long and 40 yards wid', and containing, therefore, just one acre each. The following is a plan of such square:



At each of the points A, B, C, and D, pegs are driven into the ground; the external lines represent strong iron wires, extending from and fastened to each of the four pegs, and communicating with each other, so as to form a square of wire, sunk 3 inches below the surface; at the points E and F poles are fixed in the ground 15 feet high; a wire is connected with the cross wire beneath the surface, at the point E,—carried up the pole and along the centre of the square to the top of the pole at F, down which it is conducted and fixed to the cross wire beneath the surface at that point. We must here remark that the square must be so formed, to run from North to South, so that the wire passing from E to F shall be at right angles with the equator. It is well known that a considerable body of electricity is generated in the atmosphere, and constantly travelling from East to West with the motion of the earth. This electricity is attracted by the wire suspended from E to F, and communicated to the wires forming the square under the surface of the ground, from the points A, B, C, and D.

It has, however, been suggested to us, by a very competent authority, who has at this moment a number of experiments going forward to test this extraordinary new power in a variety of ways, that any quantity of electricity could be generated that might be required, by placing under the ground, at the point G, a bag of charcoal, and plates of zinc at the point H, and to connect the two by a wire passing over two poles similar to those at E and F, and crossing the longitudinal wire passing from those points.

The cost at which this application can be made is computed at *one pound* per acre, and it is reckoned to last ten to fifteen years, the wires being carefully taken up and replaced each year. We may mention the result of an experiment on a small scale of the effect of electricity on vegetation. Two small parcels of mustard seed were sown; to one electricity was applied, the other was left to its usual course: the result was, that while the former grew three inches and a half, the latter grew one inch. We should also state, that the barley produced at the rate of thirteen quarters and a half to the acre, weighed nearly two lbs. more to the bushel than any other in the neighborhood. This discovery is likely to present a very full compensation for the exhaustion of Ichaboe.—*Scotch paper.*

To Preserve Milk.—At this warm season, it may be interesting to some of our readers to know, that Johnston, in his Agricultural Chemistry, says: "An easy way of preserving milk or cream sweet for a longer time, or of removing the sourness when it has already come on, is to add to it a small quantity of the common soda, pearl ash, or magnesia of the shops.—Enough is added, when a little of the milk poured into boiling water no longer throws up any curd. If milk be introduced into bottles, be then well corked, put into a pan with cold water, and gradually raised to the boiling point, and after being allowed to cool, be taken out and set away in a cool place, the milk may be preserved perfectly sweet for upwards of half a year." He says, another mode is, to evaporate it to dryness by a gentle heat, under constant stirring. By this means a dry mass is obtained which may be preserved for a length of time, and which, when dissolved in water, is said to possess all the properties of the most excellent milk. It is known in Italy by the name of *latteina*.

SHEPARD'S ANALYSES

Of Cotton-Wool, Cotton-Seed, Indian Corn and the Yam Potato.

I.—COTTON WOOL.

One hundred parts weight of cotton wool on being heated in a platina crucible, so long as brightly burning gas continued to be emitted, lost 86.09 parts—the residuum being a perfectly charred cotton, which, on being ignited under a muffle until every particle of carbon was consumed, lost 12.985, and left almost a purely white ash, whose weight was rather under 1 per ct. or, 0.9247. Of this ash, about 44 per ct. was found to be soluble in water. It contained 12.88 per ct. of silicious sand, which must have been acquired adventitiously in the process of harvesting the fibre. Deducting the sand from the ash, the constitution of the latter is as follows:

Carbonate of Potassa (with possible traces of Soda)	44 19
Phosphate of Lime with traces of Magnesia	25 44
Carbonate of Lime	8.87
Carbonate of Magnesia	6 85
Silica	4.12
Alumina (probably accidental)	1 40
Sulphate of Potassa	2 70
Chloride of Potassium, Chloride of Magnesium, Sulphate of Lime, Phosphate Potassa, Oxide Iron in minute traces, and loss	6.43
	100.00

But since it is obvious that the carbonic acid in the above mentioned salts must have been derived during the incineration of the cotton, the following view will more certainly express the important mineral ingredients abstracted by the cotton from the soil for every 100 parts of its ash:

Potassa (with possible traces of Soda,)	31.09
Lime	17.05
Magnesia	3.26
Phosphoric Acid	12.30
Sulphuric Acid	1.22
	64.92

For every 10,000 lbs. of cotton wool, then, about 60 lbs. of the above mentioned ingredients are subtracted from the soil in the proportion indicated by the numbers appended, i. e. omitting fractions:

Potassa	31 pounds.
Lime	17 "
Magnesia	3 "
Phosphoric Acid	12 "
Sulphuric Acid	1 "

Several queries were submitted to me along with the sample to be analyzed, relative to the effect of soils on cotton. I regret to state that the almost total ignorance in which we are still left respecting the composition of the varieties of this fibre, and the soils producing them, prevents me from hazarding any explanations on the subject. This is the first destructive analysis ever made (at least so far as my knowledge extends) of the cotton wool. Nor am I acquainted with the properties of the soil which afforded it. Prior to any deductions, it is clear we must know the composition of each variety of cotton, as well as that of the soil it affects. At present I can only venture on connecting together two facts, which appear to occupy important relations to one another. The soil of St. Stephen's, which is said by F. A. Porcher, Esq., to be a stiff clayey loam, produces the strongest and finest fibre of the Santee varieties. The Sea Island qualities are supposed to owe their superiority to the use of marsh-mud, which I have ascertained to be a clayey admixture, rich in alkalies and alkaline earths. Whether the similarity between these two staples is influenced most (if it is affected at all) by the chemical or mechanical qualities of the soils producing them, it is impossible to decide. It is also conceivable that the two sets of qualities may conspire to one and the same end.

II.—COTTON SEED.

One hundred parts, heated as above, lost 77.475, and the thoroughly charred residuum burned under the muffle, left 3.856 parts of a perfectly white ash. The composition was found to be as follows:

Phosphate of Lime (with traces of Magnesia)....	61.64
Phosphate of Potassa (with traces of Soda).....	31.51
Sulphate of Potassa.....	2.55
Silica.....	1 74
Carbonate of Lime.....	0.41
Carbonate of Magnesia.....	26
Chloride of Potassium.....	25
Carbonate of Potassa, Sulphate of Lime, Sulphate of Magnesia, and loss.....	1.64
Alumina and oxides of iron and manganese in traces,	
	100.00

In comparing the above table with that afforded by the cotton wool, a marked dissimilarity presents itself. The ash of the cotton seed is fourfold that of the fibre: while the former has also treble the phosphoric acid possessed by the latter, as will the more clearly appear, when we present the analysis under another form, corresponding with the second table under cotton wool:

Phosphoric Acid.....	45.85
Lime.....	29.79
Potassa.....	19.40
Sulphuric Acid.....	1.16
	95.70

From the foregoing analysis it would appear difficult to imagine a vegetable compound, better adapted for fertilizing land, than the cotton seed; nor can we any longer be surprised at the well known fact, that soils long cropped with this staple without a return to them of the inorganic matters withdrawn in the seed, become completely exhausted and unproductive.

III—INDIAN CORN.

One hundren parts heated to redness in a crucible, so long as a brightly burning flame was emitted, lost 81.05 parts. The completely charred residuum on being ignited beneath a muffle upon a platina foil, until all the carbon was consumed, left 0.95 parts, or less than 1 per cent. of an easily flowing clear glass. This ash has the following composition:

Silica.....	38.45
Potassa, (with traces of Soda).....	19 51
Phosphate of Lime.....	17.17
Phosphate of Magnesia.....	13.83
Phosphate of Potassa.....	2.24
Carbonate of Lime.....	2.50
Carbonate of Magnesia.....	2 16
Sulphate of Lime, Sulphate of Magnesia, ...	79
Silica, mechanically present.....	1 70
Alumina traces.....	
Loss.....	1.65
	100.00

Omitting the silica as an unimportant loss to the soil, and the carbonic acid which is a product of the analysis, we have in every 100 parts of the ash of the Indian corn, the following important inorganic constituents:

Potassa,.....	20.87
Phosphoric Acid,.....	18 89
Lime,.....	9.72
Magnesia.....	5.76
	55.15

That is to say, for every 1000 pounds of Indian corn sold from an estate, the land is robbed of 9½ lbs. inorganic matter, whereof about 5½ lbs. consist of principles of prime value to all species of crops.*

IV.—SWEET POTATO, (YAM.)

The tubers analyzed, though fresh from the market, were obviously drier than when first harvested.

One hundred parts of the thinly sliced tubers, on being thoroughly dried at a temperature of 200°, lost 58.97 per cent. of water.

One hundred parts of the undried potato gave 1.09 parts, or rather over one per cent. of a whitish ash stained in points of a bluish green color.

Its composition was as follows:

Carbonate of Potassa, (with traces of soda).....	60.00
Phosphate of Lime,.....	14.57
Phosphate of Magnesia,.....	5.60
Carbonate of Lime,.....	5.39
Carbonate of Magnesia,.....	3.80
Chloride of Potassium.....	4.60
Sulphate of Potassa,.....	4.35
Silica,.....	70
Chloride of Calcium, Sulphate of Magnesia and Lime, Alumina, and loss,	99
Oxides of Iron and Manganese in traces,	
	100.00

One hundred parts of the ash from the sweet potato tuber, contains then the following inorganic principles, which must have been withdrawn from the soil:

Potassa.....	43 59
Phosphoric Acid.....	11.08
Lime.....	10.12
Magnesia.....	3.80
Potassium.....	2.42
Chlorine.....	2.18
Sulphuric Acid.....	1 90
[S. C. Temperance Advocate.]	85.09

From the Spirit of the Times.

THE HORSE.

"Think, while we talk of horses, that you see them
Printing their proud hoofs i' the receiving earth."
SHAKSPEARE.

All horses of a superior kind are said, and with evident probability, to have proceeded primarily from Candahar, Cabul, Mooltan (the ancient Bectria and Sogdiana,) and more particularly from Punje-Awb, a tract so denominated because it is situated between five streams, which, in Mooltan, join the great River Indus, or Scinde, that runs into the Persian Sea; just as Mesopotamia was styled by the Greeks "Inter amnas," from being in the midst of two rivers, and the same extent by the Persians Doo-Awb, two waters, from its position between the Tigris and Euphrates. Punje-Awb is celebrated for its luxuriant pastures, which have reared for many ages a considerable number of fine horses. Dealers from the Turcoman, Usbec, and Calmuc Tartars, as well as from every part of Persia and India, repair to Lahore and its confines for the purchase of colts, and also of young camels and dromedaries, which they carry off, lightly laden with fruits, shawls and furs, in numerous caravans. A toll being exacted for every horse on the frontier of every province through which they pass, the price of them before they reach their destined market is rendered proportionably dearer.

From the countries above mentioned, this paramount breed of horses spread, in process of time, eastward to India and China; northward to Tartary; westward to Persia, Syria, and Asia Minor; and southward to Arabia, Egypt, Abyssinia, Ethiopia, Lybia, Numidia and Mauritania. From the northern coasts of Africa the Moors transported them into Spain, and thence they were introduced into every part of Europe.

Climate, assortment of food, exuberance of herbage, daintiness or coarseness of fodder, and training or management, create the difference observable in the bulk, shape and quality of horses. From the rank grass upon which they feed in Holstein, Freisland, and the Netherlands, the Flemish, Dutch, and Jutland horses become of an extraordinary corpulence and stature. Such, under the designation of Flanders mares, were formerly fashionable in England for the equipages of courtly dames, but they are now solely and properly confined to the dray.

"A perfect horse," says Camerarius, "is an assemblage of the excellency of many animals. He should possess three parts like a woman—an expanded chest, protuberant hips, and a long mane. In three things he should resemble a lion—in ferocity of countenance, in fortitude, and irresistible impetuosity. He must have three things appertaining to a sheep—the nose, gentleness, and patience; three of a mule—strength, perseverance, and sureness of foot; three of a deer—head, legs, and skin; three of a wolf—throat, neck, and hearing; three of a fox—ears, tail, and rate of trot. Three of a serpent—memory, sight, and flexibility; and three of a hair—running, walking, and pertinacity." The walk of a partridge, which in its air and gait, is most stately and graceful, would have been a more apt similitude.

The horse is, in temperament, generous and proud; in frame vigorous and powerful. He is a gregarious and sociable animal. When they assemble in herds of five or six hundred, whilst grazing or sleeping, they have constantly a sentinel on the watch. When this vidette perceives a human figure, he approaches confidently both to examine and to intimidate him. If the man advances he snorts, as a signal of alarm, upon which the herd instantly escapes; the vigilant sentinel bringing up the rear and biting those which are hindmost. He calls by neighing, and fights by kicking and biting. The wild ass is his inveterate foe. He rolls when he sweats. He eats grass closer than the ox, and in evacuating, disseminates the seeds that remain undigested. He never vomits. He is more peculiarly hurt externally by a stroke upon the ear or on the stifle, by being caught by the nose in barnacles, and by rubbing his teeth with grease. He is injured internally by the herbs padus, phalandria, crucalio, and canops, but devours hemlock without annoyance.

The mare goes with foal three hundred and thirty-seven days. The longer animals are in gestation, and vegetables in their progress to maturity, the more noble is their kind. A rapid growth in animals or vegetables makes no provision for solidity or duration. "Non enim potest in eo esse succus diuturnus, quod nimis celeriter est maturitatem assecutum."—*Cicero de Oratore.*

"Round hoofed, short jointed, fetlocks shag and long,
Broad breast, full eyes, small head and nostrils wide,
High crest, short ears, straight legs, and passing strong,
Thin mane, thick tail, broad buttocks, tender hide."
Shakspeare's Horse of Adonis.

The stag-necked horse, says Lavater, has something in the make of his body much resembling the stag itself. The neck is large and scarcely bowed in the middle; he carries his head high. They are racers and hunters, being particularly adapted for swiftness by the make of their body.

The hog-necked has the neck above and below alike broad, the head hanging downwards, the middle of the nose is concave in profile, the ears are long, thick, and hanging, the eyes small and ugly, the nostrils small, the mouth large, the whole body round, and the coat long and rough.

These horses are intractable, slow and vicious, and will run their rider against a wall, stone, or tree. When held in, they rear and endeavor to throw the rider. Blows or coaxing are frequently alike ineffectual; they continue obstinate and restive.

If we examine, says the same author, the different heads of horses, we shall find that all cheerful, high-spirited, capricious, courageous horses, have the nose-bone of the profile convex, and that most of the vicious, restive, and idle, have the same bone flat or concave.

The grey is the tenderest of horses; and we may here add that people with light hair, if not effeminate, are yet, it is well known, of tender formation and constitution. The chesnut and iron-grey, the black and bay are hardy; the sorrel are the most hardy, and yet the most subject to disease. The sorrel, whether well or ill-formed, is treacherous; all treacherous horses lay their ears in the neck, they stare, and stop, and lay down their ears alternately.

When a horse has broad, long, widely separated hanging ears, we are well assured he is bad and sluggish. If he lays down his ears alternately, he is fretful and apt to start.

Thin pointed and projecting ears, on the contrary, denote a horse of good disposition.

We never find that the thick, long-necked horse, is sufficiently teachable for a riding horse; or that he is of a strong nature, when the tail shakes like the tail of a dog. We may be certain that a horse with large cheerful eyes, and a fine shining coat, if we have no other tokens, is of a good constitution and understanding.

*In a recent number of the Boston Journal of Natural History, I observe some observations by Dr. Charles T. Jackson, on the inorganic constitution of Indian corn, wherein Dr. J. supposes phosphoric acid to be present in the grain, in a free or uncombined state.—The experiment which led him to form this conjecture, did by no means succeed in my hands as described by him; for although the grain was repeatedly incinerated upon a bright platina foil under muffle, still the metal lost none of its polish or malleability. Neither can I agree with Dr. J. in his opinion of the presence of ammonia as a base in Indian corn, the volatile alkali obtained by him, being a product rather than an educt of the analysis.

Suggestions for Southern Planters.

From the Southern Agriculturist.

The present is the darkest day of our agriculture. We have all been reared up under a *cotton regime*. Suddenly its power and vitality are gone, and we are prostrate. The pivot of all our movements, the fulcrum on which rested all our hopes, is struck from us, and despair and ruin look us right in the face. In our confusion, darkness and hopelessness, a multitude of schemes for our salvation are proposed. A combination to reduce the cotton crop is loudly called for. This is plainly impracticable. All will not agree; and if all agreed, not one would feel safe in trusting his neighbor, much less his competitor a thousand miles off. Immigration is a remedy some propose; this is a doubtful one, or at least partial, since few can or will adopt it: and so far as it goes, destroys, instead of renovating our region. A prominent suggestion is to embark in manufactures. It is an American fallacy, that all men are born not only equal, but, like Minerva, full grown, armed and prepared for everything. We seem to think with Dogberry, that learning comes by nature. The truth is quite the reverse; and when it is proposed to regenerate a full grown cotton planter, and convert him into a manufacturer, for one, I feel like putting the question of Nicodemus, "How can a man enter into his mother's womb and be born again?" But we may employ agents. How? sell our negroes, give away our lands, and place our all (for all would be but little compared with the requisitions of factories on a profitable scale,) into the hands of strangers, to be invested in a business about which we know nothing, and cannot hope to learn much, before it may be too late? We have some experience in these matters—vide the early history of Vaucluse and Saluda Factories, and many others which might be named. Let speculators speculate in factories. "*Ne sutra ultra crepidam*," though a pagan maxim, is a wise one. If the cotton planter is to work out his own salvation and redeem his country, it must be in his own line of business. This may be taken for granted. He is a child of the sod, reared upon the sod, and he must live or perish on it. All shifts are vain. It is only making bad worse, to rush into radical changes, and "fly from present ills to others that we know not of." Having made up our minds to hold on to our native soil, to the occupation we have been trained to, and to baptize ourselves anew "in the sweat of the brow," let us look around and see what can be done.

The first thing that strikes us is, that we have been under a *cotton growing delusion*, and sacrificed everything to it. When our soil was fresh and cotton high, we abandoned all other culture, and purchased with our cotton a vast deal that we might have made or grown ourselves. It is, however, folly to quarrel with the past; nor do I think our quarrel just. Why might not the cotton planter buy everything, even to his corn and butter, as well as the cotton manufacturer, if he found it to his advantage to plant cotton exclusively? And for a time such was the case. Our errors were in carrying on this system too long, and in exhausting our soil too far. These we must retrieve: Not violently or suddenly, by radical revolutions, or slight-of-hand contrivances or combination; but gradually, and on the same base line that our past operations have been conducted. We all know something about making and applying manures; we can readily learn all that is known every where, the world over; the facts are few, the principles simple, and our experience and course of reflection have prepared us to comprehend and apply them to our own profit; while nature has been prodigal of the resources furnished us for the purpose. We have lime, marl, peat, muck, salt-marsh, pine-straw, oak leaves, and almost every variety of mineral and vegetable material for compost. All that is wanted is resolution to embark vigorously, and to the proper extent in the matter. Our farms will be our factories, our own slaves our operatives, ourselves must be the managers, no outlay or very little is requisite. If we are so foolish as to estimate the cost and profits of extensive manuring, by comparing it with past cotton planting, of course we will conclude that it would be ruinous; but compare it with present cotton planting, and it will be seen that every planter can profitably engage one fourth or more of his whole force in making manure at this time; and the prospective advantages are still greater. Though no one else should do it, and no diminution of cotton ensue, still it is certain, that cotton must sooner or later run up and command a speculative price, every now and then, for a year or two at a time. The planter whose land has been enriched by manure, may then, if so disposed, exhaust it again, and coin his deposit of compost, in "*mint drops*." He will have lent labor worth but little, and got back in due season golden usury; while the value of his lands has been vastly enhanced, his whole scheme of management expanded and improved in every direction, and his happiness inestimably increased in seeing every thing about him flourish luxuriantly—big stalks of cotton and big ears of corn, fat hogs and cattle, greasy faced, smiling negroes, strong sound fences and substantial barns, stables and negro houses.—All these things follow inevitably in the train of heavy manuring. Less actual money there may be for the moment, but more comfort, more satisfaction and brighter hopes. Here is the sure remedy for the error of exhausting our soil heretofore. It is also the only remedy. Slow, laborious, requiring infinite pains, but it is the one way, and happily the certain way.

The evil of over-buying has an equally sure and fruit-bearing remedy. To show that I am no enthusiast, I will say that I doubt very much whether we shall ever be able to make our own cloths, blankets, bagging, even our shoes, and most plantation implements, any more than we can make our salt and iron as cheap as we can buy them, even with cotton at five cents. It is true, that, according to locality, each one can do something at them; nearly all can furnish wool and hides to some extent, and make a great many little articles now foolishly purchased; while the whole may be made by persons who understand the business within the State. But our corn, meat, flour, rice, tobacco and butter, it is positively disgraceful for any cotton planter to continue to buy. There is no five miles square in the State that is settled, but has suitable soil for growing enough rice, tobacco and wheat for its own consumption at least, and on which machinery of some sort might not be erected to prepare them for use at a saving expense. As to that glorious grain, Indian corn, it grows every where, and is the best gift of Providence to man. The Athenians worshipped Pallas for bestowing the olive; but the olive, the vine, and the products of the bee combined, are not to be compared to our maize. It is bread, drink, and sweetening. From the tassel to the root, fruit, leaf, stem and husk, all are of inestimable value; and no where can it be cultivated to better advantage than with us. On sand or clay, swamp or mountain, it flourishes every where; and he is not a true man, who does not out of sheer gratitude, grow it till every granary overflows, and every maw about him is ready to burst with it. And can it be said, that with such a resource we cannot raise meat in abundance and to spare? From the first of June until frost, it may be soiled cheaper than clover, or than the best lands can be pastured. From thence to June again, it may be ground up alone, or corn-cob and shuck together, or fed without preparation at all, the stalks and leaves also—all equally grateful to every animal, and the cheapest as well as best food in the world. The cultivation and use of Indian corn is in its infancy. The time is fast approaching when those who can use it, will look with contempt upon every other grass in the world, and provide meat for most of those who are without the pale of its bounty. In the meantime, however, we can grow turnips, carrots, beets, artichokes and that other invaluable root, sweet potatoes. With the help of these, we can rear every species of animal at as little cost and to as great perfection as can be done any where on earth. It is a great and injurious mistake to suppose, that because our ranges are becoming exhausted, and our climate forbids, as I believe it does, the grasses cultivated elsewhere, that this is not a stock raising country. I am convinced it is equal to any other for that purpose. We are in a great measure exempt from the excessive heats, droughts, and wet spells further South and Southwest, as well as their pestiferous insects. Our State is well watered throughout, and this single advantage over the lime-stone regions of the West so famous for stock, is enough to turn the scale in our favor; while there and further North, every thing is pinched with cold for eight months in the year, and for many of them the ground is covered deep with snow. Let the fact speak for itself. Who has failed, that has attempted to raise animals here and taken the necessary pains? From the highest blooded cross of the Arabian and Barb, to the English Rabbit, every thing has been reared to perfection. It is only necessary to turn our attention seriously to it, and take the necessary trouble, to do it cheaper than it can be done elsewhere.

The evil of over-buying is confined chiefly to articles for provisions, and I have shown the remedy here. Like manuring, it is slow, laborious, and pains-taking; but as the two evils mentioned are intimately allied, so the two remedies suggested, mutually act and re-act on one another. Manure makes corn—corn-stalks, stock—stock, manure. Let them be therefore combined. It is idle (American humbug) reliance upon the magic of majorities, or the alchemy of transmuting, not metals only, but men, to talk of conventions to reduce the culture of cotton; or immigration to relieve the pressure of the times; or manufacturing to divert our labor. Let every man set about restoring his worn-out lands, and sacredly abstain from all bread and flesh not produced by himself, and a few short years will rejuvenate South Carolina, and make every one of her sons rich in money—and what money cannot purchase, contentment.

We should never doubt the providence of God. The greatest blessings often come to us in the appearance of the greatest evils. In our entire devotions to mere cotton growing we have neglected the rich resources bestowed upon us, and the culture of crops far more important to both our moral and physical well being. The time has arrived when to do so longer, might be a lasting injury to us. Let us be grateful to Him, who through only temporary suffering, recalls us from our errors, and holds out to us such lavish rewards for doing right. For our own good, and for the welfare of our species, the agricultural capabilities of our State must be developed. With cotton at five cents, this will be more fully done in ten years, than it would be in as many centuries, perhaps, with cotton at ten cents. A wiser forecast than our own has ordained our task, and if we would imitate that wisdom, we must address ourselves to its accomplishment. HOLKHAM.

HINTS TO HOUSEKEEPERS.—Woollens should be washed in very hot suds and not rinsed. Luke-warm water shrinks them.

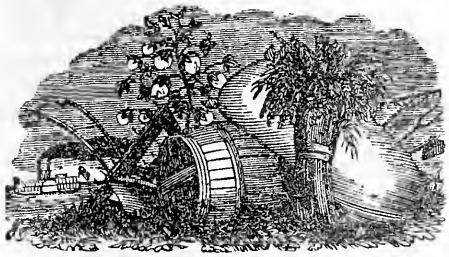
Suet keeps good all the year round, if chopped and packed in a stone jar, and covered with molasses.

When molasses is used in cooking, it is a prodigious improvement to boil and skim it before you use it. It takes out the unpleasant raw taste, and makes it almost as good as sugar.

Use hard soap to wash your clothes, and soft to wash your floors. Soft soap is so slippery that it wastes a good deal in washing clothes.

It is easy to have a supply of horse-radish all winter. Have a quantity grated while the root is in pertection, put it in bottles fill it with vinegar, and keep it corked tight.

Do not wrap knives and forks in woollens; wrap them in strong paper. Steel is injured by lying in woollens.—*American Traveller.*



The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 8.....AUGUST, 1845.

Improvement of Soils.

Our correspondent, Mr. N. Ashley, propounds inqulries as to the effect of putting clay, swamp mud, and lime, on the light sandy soils of the piney woods.

So much depends on the character of the sand, clay and mud which it is proposed to mix together, and so much on the minuteness with which these ingredients have been divided, by the action of air and water, and the intimacy with which they shall be blended together, that the precise effect of such mixture can be determined only by careful experiment. If Mr. Ashley will take an acre of his light, sandy soil, and experiment upon it, carefully noting the result, and keeping an account of the expense, he will soon be able to determine for himself what his interest requires him to do. In the meantime, if any of our readers, situated as Mr. Ashley is, have turned their attention to this subject, and are able to throw any light upon it, we would be pleased to have the results of their experience laid before the public in the pages of the Cultivator.

As regards the use of swamp mud, we have a statement by the committee of the Pendleton Agricultural Society, who examined the farm of Mr. R. A. Maxwell, of an experiment at manuring a very exhausted piece of land with leaves spread upon the surface and plowed in, and *a spade full of swamp mud* to each hill. The result, the committee say, when compared with a portion of the same field not thus managed, was said to be *the difference between an ear and a nubbin*. Still, we do not mean to say that because the application of swamp mud made ears in place of nubbins in Pendleton District, South Carolina, the same result will certainly follow in Telfair county, Ga., until we know the chemical character of the mud in both cases. It remains for actual experiment to determine what the result will be in the latter case.

So far as our own experience and observation have gone, we are entirely satisfied that all light, sandy soils are wonderfully improved by the addition of clay and lime. As regards the addition of clay, our experiments have consisted in bringing a clay subsoil to the surface and mixing it with the light gravelly top soil. The good effects of such an operation on the soil have been very satisfactory indeed. And we imagine that most persons tilling the light, sandy soil of the piney woods will find it least expensive to bring up the clay that usually underlies the sand, and incorporating it with the sand, either by subsoil or trench plowing. As for lime it is so essential an ingredient in all good soils, both as a mechanical and chemical agent, that even the spoonful to the hill proposed by Mr. Ashley must be better than none. The analysis of soils quoted in the subsequent part of this article, must convince every one of the indispensable necessity of the presence of large quantities of lime in all soils that admit of very profitable cultivation for a long series of years. In Pennsylvania formerly one hundred bushels of lime to the acre every ten years was considered a moderate application of it. Mr. Patterson, of Springfield, Carrol county, Maryland, in reclaiming the poor, worn out land of his estate, commences by putting on two hundred bushels of unslaked lime per acre, which is equal to about four hundred bushels of lime, as usually applied. He lets it lie undisturbed for two or three years, and then incorporates it thoroughly with the soil, adding all the manure he can get. Even this very heavy dressing of lime is found not to be too much. In our piney woods, in very many places, lime may be applied with equal liberality; for this region, so much needing lime, has the singular advantage of having in many localities, convenient of access, deposits of shell marl of sufficient extent to answer all the demands of its Agriculture for lime, for hundreds of years to come. A careful geological survey is all that is wanting to bring these hidden treasures to light.

On this subject of mixing sand, clay and lime together to improve the soil, what do the books say? With the reader's leave we will look into them a little. The first thing that strikes us is the fact that, without exception, they all urge upon us the importance of correcting the excess of clay by the addition of sand, and of sand by the addition of clay, perfecting the whole by a plentiful supply of lime.

Davy, in his 4th lecture on Agricultural Chemistry, says:—If on washing a sterile soil it is found to contain the salt of iron, or any acid matter, it may be ameliorated by the application of quick lime. If there be an excess of calcareous matter, it may be improved by the application of sand or clay. Soils too abundant in sand are benefited by the use of clay, or marl or vegetable matter. A deficiency of vegetable or animal matter must be supplied by manure. The best natural soils are those of which the materials have been derived from different strata, which have been minutely divided by air and water, and are intimately blended together: and in improving soils artificially, the farmer cannot do better than imitate the processes of nature. The materials for the purpose are seldom far distant: coarse sand is often found immediately on chalk, and beds of sand and gravel are common below clay. The labor of improving the texture or constitution of the soil is repaid by a great permanent advantage: less manure is required, and its fertility is insured."

These instructions of Davy were delivered annually for ten years before the Board of Agriculture, viz. from 1802 to 1812; and the whole series of eight lectures was published in 1813. Ten years afterwards, to wit, in 1823, Chaptal published his work—"Chemistry applied to Agriculture." Davy's doctrines had, therefore, been subjected to the test of practical experiment for nearly twenty years, and were then confirmed by the scientific researches of Chaptal. In the 4th article of his 2d chapter Chaptal says: "The best basis for good lands is a mixture of lime, silica and alumina; but in order that they may possess all the desirable qualities, it is necessary that certain proportions, which an analysis of the best lands has made known, should be observed in the mixture." What these proportions are, he tried to establish by an analysis of the best soils of various climates, made by scientific men in whom the utmost confidence could be placed.

One of the most fertile soils in Sweden was found by Bergmann to consist of

Coarse Silex	30 parts.
Silica	26
Alumina	14
Carbonate of Lime	30
	100

A fertile soil from the neighborhood of Turin, analysed by Giobert, was composed of

Silica	77 to 79
Alumina	9 to 14
Carbonate of Lime	5 to 12

Tillet, at Paris, made a great number of experiments in making fertile mixtures, of which the most fertile contained:

Coarse Silex	25
Silica	21
Alumina	16.5
Carbonate of Lime	37.5

An excellent wheat soil from near Drayton, in Middlesex, England, gave, on analysis,

Carbonate of Lime	28
Silica	32
Alumina	39

These results are to be understood as excluding animal and vegetable matter, and water.

The reader, on referring to Chaptal's work, will find statements of the analysis of other fertile soils; all, however, showing the same general result, and going to establish his doctrine, that the fertility of soils diminishes in proportion as one or the other of the three principal earths, lime, sand, or clay predominates, and becomes almost nothing in those which possess the properties of but one:—and, therefore, that the mixture of these earths is necessary to the formation of a productive soil.

In 1832, nine years after the publication of Chaptal's work, Edmund Ruffin, of Virginia, published his "Essay on Calcareous Manures." In the 1st Chapter of Part I, he says: "The *earths* important to agriculture, and which form nearly the whole of the known globe, are only three—*silicious*, *aluminous* and *calcareous*. All the earths, when pure as they are ever furnished by nature, are entirely barren—nor would any addition of putrescent manures enable either of the earths to support healthy vegetable life. The mixture of the three earths in due proportions, will correct the defects of all, and with a sufficiency of animal or vegetable matter, putrescent, and soluble in water, a *soil* is formed in which plants can extend their roots freely, yet be firmly supported, and derive all their needful supplies of air, water and warmth, without being oppressed by too much of either."

In 1841, Johnston's Lectures on Agricultural Chemistry and Geology were published. In the lecture on the improvement of soils by mechanical means, he says: "There are some soils so obviously defective in constitution, that the most common observer can, at once, pronounce them likely to be improved by mechanical admixtures of various kinds. We naturally impart consistence to a sandy soil by an admixture of clay, and openness and porosity to stiff clays by the addition of sand. The good effects which almost invariably follow from the addition of clay to peaty or sandy soils, are due to the production, at on and the same time, of a physical and of a chemi-

cal change. They are not only rendered firmer, or more solid, by the admixture of clay, but they derive from this clay, at the same time, some of those mineral substances which they previously contained in less abundance. The addition of marl to the land acts often in a similar, two-fold capacity. It renders clay lands more open and friable, and to all soils brings an addition of carbonate and generally of phosphate of lime, both of which are proved by experience to be not only very influential but to be absolutely necessary to healthy vegetation."

Of the same general import are the conclusions of a still later authority—Boussingault. On page 206 of his "Rural Economy," it is asserted that "The quality of an arable soil depends essentially on the association of these two matters: —sand, whether it be silicious, calcareous or felspathic, always renders a soil friable, permeable, loose. * * * * Clay possesses properties entirely opposed to those of sand. —The proper character, or, if you will, the quality of a soil, depends essentially on the element which predominates in the mixture of sand and clay that composes it—and between the two extremes, which are alike unfriendly to vegetation, viz. the completely sandy soil, and the unmixed clay, all the other varieties, all the intermediate shades can be placed." And at page 214, after having minutely described the character of clay and sand, and certain alkaline and earthy salts, of which carbonate of lime is the principal and most important, he asserts that "the mineral substances which we have now studied, taken isolatedly, would form an almost barren soil; but by mixing them with discretion, a soil would be obtained presenting all the essential conditions of fertility, which depe id, as it would seem, much less on the chemical constitution of the elements of the soil than on their physical properties, such as their faculty of imbibition, their density, their power of conducting heat, &c., &c."

These results of scientific research merely confirm the conclusions that the common sense of mankind had arrived at, long before the attention of science was directed to the subject. But they have been very rarely applied to practice, except as to the application of lime, simply because of the great expense of digging up and transporting clay and sand from places where they are in excess to those where they are deficient. And this, after all, is the main consideration—the question of expense we mean. Prudent men must ever so regard it. Boussingault tried it on his own lands, and came to the conclusion that "it would be better policy to buy new lands with the capital which would be required to improve those he already possessed in the manner which has been indicated." And he adds that he "should have no difficulty in citing numerous instances where improvements by mingling the different kinds of soil were ruinous, in the end, to those who undertook them." So, also Johnston, with true practical wisdom, says, "the only question on the subject that ought to arise in the mind of a prudent man, is that which is connected with the economy of the case. Is this the most profitable way in which I can spend my money? Can I employ the spare labor of my men and horses, in any other way which will yield me a larger return?"

Plow deep to secure your crops from drought.

Improved Breed of Cattle.

We have been furnished with a description of an extraordinary calf, of the Durham stock, belonging to Dr. H. J. Bates, of Covington, Newton county, Ga. The dimensions were, on 2d June last, as follows:

4 feet 10 inches in height,
7 " 10½ " " length,
4 " 8½ " " girth behind the shoulders,
20½ " " round the arm near the body,
Supposed weight 480, or 500 pounds
Age, when measured, 1 year, 3 months and 6 days.

We believe we are safe in saying that almost every attempt to introduce the improved breeds of cattle into the southern States has ended in disappointment. They are liable to be attacked by a fatal disease, which is thought to be inflamation of the brain. The first symptom is a very languid appearance of the animal. Loss of appetite follows—then short, quick breathing, and fever, and sometimes cough—all ending in death. To avoid this result, as far as possible, it is recommended that none but young cattle be imported—to bring them into the country early in the fall—to feed well with good hay through the winter—to turn them out in spring to good pasture of tender, succulent grass, where there is easy access to pure water and abundance of shade. Through the latter part of summer and in the fall, they should be kept in a cool stable during the heat of the day, and during the night also—as it is thought the dews of September are as injurious as the heat of the midday sun in summer. If with such treatment they can be kept alive for two years, they may, perhaps, stand the climate, provided always they can get something besides shucks to eat in winter, and something better than sedge grass pastures to range in during summer.

Would it not be better to depend on our native stock? It appears to us that all we need in the southern States, to enable us to have beef, milk, butter, and cheese as good as man can desire, is, in the first place, judicious selections from our own stock—then good pasture in summer—plenty of hay and good shelter in winter—and gentle treatment at all times. With means of this sort in abundance, our native stock will be found, we think, to answer all our purposes; especially if our servants, and very many masters, too, can be induced to remember that there is some little difference between a cow and a mule, as to the manner in which they should be treated. What else than blue-john, in the very highest state of perfection, can be expected from cows fed on shucks and exposed to wind and rain all winter—turned out to sedge-grass pastures in spring, and brought up every evening in a trot or gallop, by the little negroes and dogs, or a big negro on horseback.

Sugar for Manure.

Did you ever hear the like of this before? A writer in an English paper, the Mark Lane Express, says: "Sugar will, now the price is reduced, I have no doubt, be extensively used. I speak from experience when I say that, of all extraneous manures (if one it may be called,) it has produced more visible effects, in the least space of time, than any other I ever used, and is strictly what the turnip requires in the first stage of its growth. I would strongly recommend it to be tried on a small scale mixed with ashes."

Prof. Shepard's Analyses.

We, at last, have an account of the inorganic elements of Cotton Wool, Cotton Seed, Indian Corn and Sweet Potatoes. See the account of Prof. Shepard's analyses of these articles in another part of this paper. Those who cultivate these crops now may know what their soil must contain to supply the inorganic constituents of such parts of these plants as have been examined. We wait anxiously for the further analyses promised of southern Agricultural productions.

Mr. Printice's Sale.

The sale of Mr. Printice's herd of improved Short Horned Cattle took place on the 25th ult, at Mount Hope, near Albany, New York. The prices at which the cattle were sold would indicate that they must have been very superior indeed. Sixteen cows, from 4 to 11 years old, went at prices varying from 80 to 215 dollars: fifteen heifers and heifer calves, from two weeks to three years old, at from 45 to 225 dollars; and ten bulls and bull calves, from three days to five years old, at from 25 to 205 dollars.

Total 41 animals.....$4,622 50
Average..... $112 75

There is some inducement for men to pay attention to the improvement of cattle when they can sell them for such prices.

An Independent Man.

It seems to us that, with a little self-denial, every man in the country might place himself in a situation like that described by the Farmer's Gazette. "We fell into conversation," says the Gazette, "a few days ago with a gentleman who resides but a short distance from Chesterfield Court House, S. C., on the subject of his farming prospects the present year. He informed us, that he expected his corn crop would prove an entire failure—but, he remarked, he had corn enough to last another year. We observed, that if the corn failed, there was but a slight prospect of *maste*, and bacon would be scarce. He assented, but said he never fattened his hogs on maste; it was his habit to plant a good pea crop, and give the hogs the run of the fields, after he had gathered his corn; but, said he, if my pea crop fails, I have bacon enough to last another year—*and, if I owe any man a cent, I don't know it!* Here, then, is a man who has an abundance of bread and meat, and has practically carried out the Scriptural injunction, 'owe no man anything.' May we not fairly set him down as *an independent man.*"

The Season.

Many persons are speaking of the past spring and present summer, up to the middle of July, as the dryest and hottest that we have ever had in the Southern States. It has been, in these particulars, very remarkable, indeed; but not without parallel by any means. A writer in a Charleston paper has been looking into the records of the past; and has furnished us with the following extracts from an account, by Dr. Chalmers, of the spring and summer of 1752.

The preceding spring having been unusually dry and not more than 5.41 inches of rain fall-

ing in May and June, we had not a shower from the 20th of the latter month till the 21st of July, the weather in the mean time being excessively hot. The consequence was that the vapors which floated in the air were so elevated by *rarefaction*, that *dews* soon failed; the great heat of the nights also contributing to their being detained aloft in the atmosphere, so that by the 13th of July a general drouth prevailed—the earth was so parched and dry that not the least perspiration appeared on plants, which shrunk and withered. All standing waters were dried up, as were many wells and springs, so that travellers could not find water, either for themselves or their beasts for a whole day together, for the soil being very light and transpirable, it was soon drained of its moisture. * * * *

In several settlements no water could be found by digging ever so deep, for which search the enclosures were laid open, and the cattle drove out to shift for themselves. But very many of them perished for want of both pasturage and water, as probably did great numbers of those birds that require drink, for none of them were to be seen amongst us. In short, the distresses of men and beast at this time are not to be described.

When the thermometer rose to the 97th and 98th degree in the shade, the atmosphere seemed to glow as if fires were kindled around us, the air being likewise so thick and smoky withall, that the sun appeared as a ball of red hot metal, and shined very faintly. * * * * Refreshing sleep was therefore a stranger to our eyes, insomuch that people were in a manner worn down with watching and the excessive heat together. Many people lay abroad on the pavements. During this season a candle was blown out and set in a chimney at ten o'clock at night, the wick of which continued to burn clearly till next morning, and was likely to do so for many hours together. * * * * The mercury rose above the 90th degree of the thermometer during the months of May, June, July and August, and for *twenty successive days*, excepting three in June and July, the temperature of the shaded air varied between the 90th and 101st division, and sometimes it must have been 30 degrees warmer in the open sunshine. *Neither was ever a more healthy season known than this*, so long as the weather continued steady, warm and fair.

Agricultural Education.

The Rev. Carlisle P. B. Martin, of Madison, Morgan county, advertising the commencement of the second term of his "Family Boarding School," informs the public, that "in connection with the usual studies, (as soon as practicable,) lectures on agricultural chemistry will be delivered before the students, and the principles of chemistry, as connected with the noble and important subject of agriculture, illustrated by experiment and analysis." Now we like this proposal. It is undertaking to do just what the country wants; and in a way too that is sure to be successful, so far as the explanation of the elements of the subject is concerned. More than this—that is, the explanation of first principles—individual effort cannot well accomplish. Indeed, beyond this it would not perhaps be well for individual effort to attempt to go. The full illustration of the subject in all its branches and details, must be the business of our State College. And the State must furnish it with the means of doing this effectually, by appropriating the money to sustain the necessary professorship. After the vast sums the State has expended for the benefit of those who are destined for the professions of divinity, law and medicine, the tillers of the ground must demand that something shall be done by the State for that profession without which none of the others could exist for a moment, and whose great business is the conversion of earth, air and water, into bread, meat and clothing. The necessity of some such provision being made by the State is becoming stronger every day, from the fact that every day the value of mere bone and muscle, as a mechanical agent, is becoming less—and must in the end become comparatively worthless in agricultural operations, unless guided by an enlightened intellect.

"I had occasion," says a writer in the London Agricultural Gazette, "to visit the son of a friend of mine, at a school of great respectability in a wealthy agricultural district. The master, a very intelligent person, showed me the details of his well-arranged establishment, which was certainly a pattern in every respect. On entering the well-filled school-room, he observed that most of his scholars were farmers' sons. Glancing at his library, I inquired what books on agricultural subjects it contained? The master seemed struck with surprise (as if the thought of such books had never occurred to him) and replied, 'With shame I acknowledge, not one; but send me a list of such as you recommend, and I will immediately procure them.' Now I apprehend this case might be multiplied by a thousand or more. Can we wonder, then, that a youth who never heard the word agriculture at school, and who is seldom or never sent into different districts to be taught agriculture as a science, should go home to his parent, and follow his plan of farming, be it good, bad or indifferent. In all other trades and professions an apprenticeship is considered essential to the acquirement of knowledge; but farming, the most necessary of all trades, is to be left to chance, or rather mischance. A system of uniformity is essential in making a hat, coat, or shoes; there are established educational rules for the church and the bar and the senate; but agriculture, the greatest interest of all, on which our very existence depends, economically and politically, is to be like a ship without a compass, tossed about by the ever-varying gale of individual opinion, without a hope of reaching the port of Perfection. Were a youth ever so much inclined to furnish his mind with comparisons and observations of the various systems of culture in our own different counties, as well as in foreign climes, there is under the present school system, no opportunity for his doing so; and no doubt he would be surprised if told that we are a century at least behind the Chinese in agricultural practice. I hope we shall soon see every school, and, in fact, every farmer's parlor, possessing a few sound practical works on agriculture. I presume no man will consider he knows every thing in agriculture—if he does, it is unfortunate for him. Little as I am acquainted with the subject, I am fully convinced that it is full of interest, and of such extent that a lifetime of study and practice would find us on the wrong side of perfection."

The Lazy Fever.

A correspondent of the American Agriculturist has furnished for that paper a recipe for the cure of that most pestilent disease known as the *lazy fever*, and sometimes the *slow fever*, copied from "The Breviary of Health, by Andrew Boorde, Physicke Doctoure—Anno 1557." We copy the recipe for the benefit of such of our readers as may happen to have about them persons afflicted with this horrible disease, that are worth curing:

"The 151 chapitre doth showe of an evyll fever, the which doth cumber yonge persons, and named the fever burden or lazy fever. *

* * Thys fever doth come naturally, or else by evyll and slouthful brynging upp. If it doth come by nature, then it is incurable; for it can never bee gotten out of the bone that is bred in the fleshe. If it be by slouthful brynging upp, it may be holpen by dylligent labour. There is nothing for the *fever burden* so good as *unguentum baculinum;* that is, take a sticke or wand, a yard of length and more, and let it be as great as a man's fynger; and wyth it anoynt the back and shoulders well, morning and evening, and doe thys 21 dayes—and if thys fever wyll not be holpen in that tyme, let them beware of waggynge on the gallowes. And whyles they do take thys medicine, put no lubberwort in theyre pottage."

Communicated for the Cultivator.

A Table of the Weather.

The following article is from the pen of the celebrated Dr. Adam Clarke, foretelling the weather through all the lunations of each year, for ever.

M'n	TIME OF CHANGES.	IN SUMMER.	IN WINTER.
If the New Moon, the First Quarter, the Full Moon, or Last Quarter, happens:	Between midnight and 2 o'clock in the morning.	Fair.....	Hard frost, unless wind be S. or W.
	Between 2 and 4 in the morning.	Cold with frequent show's	Snow and stormy.
	Between 4 and 6 A.M.	Rain	Rain.
	Between 6 and 8 "	Wind & rain.	Stormy.
	Between 8 and 10 "	Changeable..	Cold rain if wind West, snow if East
	Between 10 and 12 "	Frequent showers.	Cold and high wind.
	Between 12 o'cl'ck at noon & 2 P.M.	Very rainy...	Snow or rain.
	Between 2 and 4 P.M.	Changeable..	Fair and mild.
	Between 4 and 6 "	Fair.....	Fair.
	Between 6 and 8 "	Fair if wind NW.; rainy if S. or SW	Fair & frosty if wind N. or N.E.; rain or snow if S. or S.West.
	Between 8 and 10 "	Ditto.	
	Between 10 and 12 "	Fair.....	Fair & frosty.

Observations.—1st. The nearer the time of the Moon's change, first quarter, full and last quarter are to midnight the fairer will the weather be during the seven days following.

2. The space for this calculation occupies from 10 at night 'till 2 next morning.

3. The nearer to midday or noon the phases of the moon happen, the more wet weather may be expected during the next seven days.

4. The space of this calculation occupies from 10 in the forenoon to 2 in the afternoon. These observations refer principally to the Summer, though they affect Spring and Autumn.

5. The moon's change, first quarter, full and last quarter, happening during six of the afternoon hours, *i. e.* from 4 to 10, may be followed by fair weather, but this mostly dependent on the wind, as noted in Table.

6. Though the weather, from a variety of irregular causes, is more uncertain in the latter part of Autumn, the whole of Winter and the beginning of Spring, yet in the main, the above observations will apply to those periods also.

7. To prognosticate correctly, especially in those cases where the wind is concerned, the observer should be within sight of a good vane, where the Four Cardinal Points of the Heavens are correctly placed; with this precaution, he will scarcely ever be deceived in depending on the Table.

Useful Directions.

Britannia ware should be first rubbed gently with a woollen cloth and sweet oil, then washed in warm suds and rubbed with soft leather and whiting. Thus treated it will retain its beauty to the last.

New iron should be very gradually heated at first; after it has become inured to the heat, it is not as likely to crack.

It is a good plan to put new earthen ware into cold water, and let it heat gradually until it boils —then cool again. Brown earthen ware, particularly, may be toughened in this way. A handful of rye or wheat bran thrown in while it is boiling, will preserve the glazing, so that it will not be destroyed by acid or salt.

The oftener carpets are shaken the longer they will wear; the dirt that collects under them grinds out the threads.

If you wish to preserve fine teeth, always clean them thoroughly after you have eaten your last meal at night.

Original Communications.

Sheep and Wool.

Mr. Camak:—Feeling a deep interest in the cause of agriculture in Georgia, and an earnest hope for the success of the Southern Cultivator, I am tempted, by a solicitation from you to its patrons, to send a few communications for publication, should you deem them of sufficient importance for the attention of its readers.

I regarded the publication of the Cultivator, at the time I first noticed its prospectus, as the harbinger of a new era for the agriculture of our State; and I do assure you, sir, that my expectations have been fully realized. The influence produced by such a work upon the minds of our people is practically illustrated. Had I the means of dissemination, I would place it in the hands of every reading planter in Georgia; for it is working wonders upon the passions and prejudices of those who have already been aroused by the lessons it inculcates. The Cultivator, in truth, has given an impulse to agriculture, wherever it has been circulated, that is really astonishing, and in those sections of country, too, where once prejudice and gross ignorance of its first principles seemed to reign. But the mist is rapidly disappearing, and we may now safely hope, that the day is passed when men, for shame of their ignorance and prejudice, will deny to their neighbors, that there is any practical knowledge of agriculture to be gained by the study of books, or that book farming is all humbug. Poor simpleton he must be, who now contents himself to "follow in the footsteps of his predecessor," or to follow plans and customs because they were the practice perhaps of his father thirty or forty years since. I am often both delighted and amused to witness the salutary influence exerted by the Cultivator in many sections of the country. It puts men to speculating, thinking and acting, who five years since considered their neighbor a visionary planter, who would embrace any new plan because it was derived from some book. These men now are not only subscribers to the Cultivator, but are active and zealous members, many of them, of agricultural associations, and are among the first to avail themselves of any new theory by which they can "grow two blades where they could only one before."

Such is the onward march of mind in every section of our State, through which I have traveled within the last two months. Then, under an awakened sense of what constitutes our dearest interest as a people, striving to add to our happiness and comfort in this life, may we not cherish the hope that greater ends may yet be effected to accomplish what we so earnestly and so devoutly seek? As the system of reform, so honorable, has begun in Georgia, is the present not an auspicious time to do something for our agriculture by legislative provision? Permit me, sir, through the columns of the Cultivator, to invoke your aid and the editorial corps of our State, in the achievement of a measure, the success of which will enhance one of the dearest interests of Georgia. It is a measure, I believe, that has been overlooked by most of the States of the Union; but why should Georgia hesitate to consummate a measure fraught with such manifold blessings to her citizens? Will our next Legislature not grant us a law for the encouragement of the raising of sheep and the production of wool? Just reflect for a moment on the tribute we pay annually for our domestic cloth, while we have a climate and soil that cannot be surpassed by any other on this globe for sheep and wool.—Yes, it is a fact that there is not such a country on the earth embracing such advantages as Georgia for the raising of sheep. I write, sir, from an experience of twenty year's trial and observation of this animal in different sections of the country. And why shall we not live and profit by advantages such as we have? We can! And if you will only bring the subject home to the people of Georgia, and impress it upon the good sense of our next Legislature, that we claim at their hands, as a people, the benefit of such a measure, it would be hailed from ocean to mountain as the richest blessing under Heaven. Then cannot some of our benevolent and enlightened legislators be induced to advocate a measure so important? My life for the issue, he who accomplishes the task, will confer as great a bounty upon his people, and build for himself a monument as high in the gratitude of his State, as Sir Walter Raleigh did by the introduction of the potato into Ireland.

The successful result of such a measure would open a new field of industry and enterprize in Georgia, and give employment to thousands of our people, who now live out a wretched and miserable existence; for men who now produce not a pound of wool, nor afford it for their families, would, in less than five years, rear sheep "upon a thousand hills."

If this branch of industry can be rendered so lucrative, as I shall, at another time, attempt to show, by an enlightened system of legislative action, then why not begin the work? There is certainly no agricultural pursuit that promises a greater return upon the outlay to the planter than the raising of sheep. I presume that there is not an intelligent man in Georgia, identified with the soil, or claiming an interest therein, who would not cordially unite in promoting this branch of industry by legislative encouragement. Then, for the purpose of accomplishing a measure of such general and vital interest to the people of the State, I suggest that the next legislature grant an act for the benefit of sheep-raisers, embracing a premium upon the quality and production of wool; a price for the head of every wolf killed within the limits of the State; and lastly, include all dogs within the State under the head of "Domestic Relations," by making your neighbor as responsible for the transgression of his dog as his slave, to be determined in courts of magistrate's jurisdiction as in common cases of "debt."

In subsequent communications under this head, I shall contrast the comparative merits of the different sections of Georgia for the raising of sheep, and the breeds best suited for those sections. Very respectfully, Jethro.

Reclusa, July, 1845.

Evaporation of Manures—Bermuda Grass.

Mr. Camak:—I noticed in the last No. of the Cultivator, a communication on the subject of "Manures—do they sink or evaporate?" Now I am fond of theory which leads to practical demonstrations; but when the latter confute the former, I am compelled to yield. In regard to manures, you may take a plat of ground in the form of a basin, (which certainly would be the best location,) to test the point. Place a sufficiency of stuff on it, that, if converted into manure by the quickest process possible, would form a coat one foot thick over the whole surface.—Now I will venture to assert, that if you let it remain in the basin until fully decomposed, it will not be two inches thick. Dig now in the soil and you will find it the same depth as before, with the addition of the manure. Now will Mr. 'Salamander' tell me what has become of the balance, if it does not evaporate? My experience as a practical farmer for about thirty years, has taught me that manure always rises and never sinks. In my early days I cultivated poor pine land, and made considerable manure, plowed shallow and manured in the hill. My reasons:—In the first place, the land was shaded by the trees, and the fall of the leaves (or straw) and grass created a sort of soil which, until it was exhausted by being exposed and cultivated, produced tolerably well. As soon as we passed through that soil, it became a continuation of coarse sand. After manuring in the hill, let there come a heavy rain and you would find a large portion of your manure in the middle furrow.—This every piney woods farmer knows. Try the experiment of digging where you have manured heavily; get below where you have plowed, and you never find your manure, nor any of the effects. The land being porous and heavy, the manure light, all the valuable properties are lost by the action of the sun.

My next experiment was on an old farm in the county of Wilkes. Here I had lands that once were very fertile, but were almost destroyed by skinning. In fact, I inquired of several farmers how they could tell how much they had in cultivation, as there appeared to be as many acres in sedge as were cultivated in the same field. My first object was to procure some of Freeborn & Hitchcock's cast iron two horse plows; the next was to get a large shovel with a wing on each side, similar to the turning scooter, the only difference being, mine was large with two wings, cleaning the furrow out well, drawn by two horses, as deep as they could pull it. Then I placed all the rough manure I could get in my stables, and corn talks trod to pieces in my lot, in those furrows, bedding on it deep with the two horse plow, (the cast iron plow.) My neighbors objected to my manure as not being sufficiently rotted. If dry, my corn would burn up they said; yet I made corn to sell. This was in 1818. I have used this kind of plow ever since, and though I may not have succeeded as well as some persons at a distance, I have generally made good crops and raised fine hogs. I have lived in this county for the last twenty-two years, and have not one foot of sedge land on any that I opened myself. I have purchased several farms that have some sedge on them.

But, sir, in stating my own experience in farming, I have necessarily left a part of the first question behind—does manure sink or evaporate? When I got on the clay lands I plowed deep. Was it because it had a foundation that would not let the manure sink? No. It had a soil, which, although exhausted, was fine and susceptible of improvement, on account of its firmness, and not so likely to suffer by evaporation. I used manure in its rough or new state, because it had not lost two-thirds of its value by evaporation, (which is the kind we farmers call well rotted.) I used that sort because it will go three times as far, and do about the same good. I plowed deep to prevent evaporation and to retain moisture, and enable me to plow my crop well. Now, in concluding the subject, I will ask any candid man, for his own satisfaction, to dig a hole (or pit) on any kind of soil, (where it has been manured the best,) and see if he can find any appearance of manure below where it has been plowed. I would go farther, and invite the chemist to test it, and then try the same quality of soil at the same depth, and I am well assured that they will agree with me that manure never sinks but evaporates.

Perhaps I ought now to quit; but there is another subject I must speak of; and that is Bermuda grass. I see it recommended by a number of intelligent gentlemen, (I cannot say farmers.) I have been acquainted with it for twenty-seven years, and have had a good deal to do with it, and think I ought to be somewhat acquainted with it. I look upon it as the worst curse a father could pronounce upon his son, to leave him a farm stocked with Bermuda grass. To old men I have nothing to say on the subject. Let them try it if they see proper. But to young farmers, let me exhort them not to be led away by the favorable opinions of others, who, I would hope, recommended it after a very partial acquaintance, but to examine some of the many fine fields in Georgia which have been and will remain cursed with it to the end of time.

Newton Co., July, 1845. A Corn Maker.

On the Application of Manure.

Mr. Camak:—What is the most proper manner of applying manure so as to derive the greatest benefit from it? I ask the question because, from the heading of an article in your May No., page 70, I conclude that you are in favor of burying in preference to top-dressing.

The writer of the article alluded to says, "There is a popular opinion that manure sinks, &c." And farther on, "But is the popular opinion true, that manure is wasted by sinking." He then goes on to prove that it is not true, by the clarifying effects of a barrel of sand, the "operations of nature" in purifying rain water, and finally adds, "I have shown that *manure does not sink, but evaporates.*"

Now, sir, I happen to be one of those persons that have imbibed that "popular opinion," and, until "Coatswood," from analysing the "nearly pure water" that runs from the barrel, can prove that it contains nothing derived from the "impure liquid manure" that would be beneficial to the growth of plants, I shall not be satisfied that none of the manure sinks even as *low* as the spiggot hole at the bottom of the barrel. But, on the contrary, I must believe, that all that is soluble of the manure, except perhaps a part of such salts as might chemically combine with the sand, comes out with the apparently pure water below. We but rarely find spring water, that has percolated through strata of many feet in thickness, entirely deprived of its impurities.

I believe that something in a gaseous form is

lost from manure in bulk, or in a situation that would cause it to heat and undergo rapid decomposition; and that the most favorable situation for a small quantity (so much, for instance, as we would place in, or on, a hill of corn) is that in which it is usually placed—*in* the hill, where it derives both *heat* and *moisture* from the surrounding soil. This being the case, is it probable that the shallow porous covering of earth will confine the gasses thus *rapidly* evolved, until taken up by the spongioles of the plants? I think not.

I furthermore believe, that in top dressing or spreading the manure on the hill, there is also something lost by evaporation—though not as much as when placed under more favorable circumstances for rapid decomposition, but, that *much more* is gained or saved by the solvent properties of rain water, which, after taking up all that has become soluble and in a suitable state for food to the plant, conveys it directly down to the roots, to be by them taken up and appropriated to its proper use. And in this way, as the manure, from its situation, becomes more slowly decomposed, its soluble parts will unite with, and be taken down by each successive shower. It seems most reasonable that, as decomposition would progress much more slowly in the latter, than in the former situation, there would be *less* loss by evaporation from a surface application, and that *more* would be saved by solution from manure placed *above*, than from that placed *below* the roots of the growing crop.

If manure is placed *under* the hill, and so low that the air cannot have access to it, then I admit there would be no loss by evaporation. Neither would there be any decomposition, and hence, not much benefit to the plant. But, by placing the manure on top, it would (even after being by tillage mixed with the surface soil) be within the influence of the atmosphere—the oxygen of which would, in combining with the woody fibre of the manure, form *carbonic acid*, "the first and most important food for young plants." Liebeg says: "Humus acts in the same manner in a soil permeable to air as in air itself; it is a continued source of carbonic acid, which it emits very slowly. An atmosphere of carbonic acid, formed at the expense of the oxygen of the air, surrounds every particle of decaying humus. The cultivation of land, by tilling and loosening the soil, causes a free and unobstructed access of air. An atmosphere of carbonic acid is therefore contained in every fertile soil, and is the first and most important food for the young plants which grow on it." Again: "By loosening the soil which surrounds young plants, we favor the access of air, and the formation of carbonic acid; and, on the other hand, the quantity of their food is diminished by every difficulty which opposes the renewal of air."

Upon the whole, I cannot agree with "Coatswood," that manure "does not sink but evaporates;" although, as above stated, I believe something may be lost. I doubt much, whether the atmosphere steals so great a portion of our manure as is suspected by many. What does it take? Carbonic acid? This gas, notwithstanding it is said to be heavier than the atmosphere, has been detected in every part of it, where its presence has been looked for; yet its specific gravity, being greater than that of the atmosphere, it may, I think, be doubted whether it *ever does*, in its uncombined state, rise from the earth into the air, unless driven off from a heated body, and in a greatly expanded form. The ammonia of manures may combine with carbonic acid and form a volatile salt (spirits of hartshorn,) and in this way sometning may be lost; but ammonia in all its forms, is extremely soluble in water, and in this way, as is the case with carbonic gas when gradually formed, may be saved by rain and even dew. Liebig says, "Liquid animal excrements, such as the urine with which the solid excrements are impregnated, contain the greatest part of their ammonia in the state of salts, in a form, therefore, in which it has completely lost its volatility; when present in this condition, not the smallest portion of the ammonia is lost to the plants; it is all dissolved by water, and imbibed by their roots." Thus we may conclude, that such salts of manures as are only soluble in water, are not likely to take wings and fly out of our fields.

I have been a constant reader of Agricultural papers since 1829, when I commenced with Mr. Skinner's eleventh volume of the "American Farmer," and have, as "Book Farmers" are apt to do, experimented much with manures. I have applied manure in almost all the different ways I have seen recommended since the above mentioned time; and I am confident that I have derived more lasting benefit from surface applications, to the corn crop especially, than in any other mode of applying it, be the *modus operandi* what it may. But, sir, the science of agriculture is onward, and we shall, I trust, learn all about the matter in dispute before long. We have new lights springing up almost daily to point out the way to that heretofore benighted and contemned class—the *most* useful and *only* indispensable of creation—the Agriculturist.

One of the first Agricultural lecturers of the day (Prof. Johnston of Scotland) is of the opinion that manure (its soluble salts) both sinks and rises in the soil; and that, although the water, which holds it in solution, does, in a dry time, evaporate from the surface, none of the salts *do*, but are there deposited, to be, by the next rain, again taken down. In this I have no doubt he is correct, and if so, for obvious reasons, the surface application is the preferable one; because, after a rain, the water, with its treasure, would necessarily have to pass the roots in its descent before it could ascend. Whereas, if the manure was placed below the plant, the salts taken from it by the descending water, would not come in contact with the roots until brought there by the ascent of the water. And this time, in which the plant would be deprived of the benefit of the manure, might be, under certain circumstances, greatly protracted, viz: in a season of continued rains, sufficient to prevent evaporation by keeping the surface moist, as the water from below will not ascend until the surface becomes dry.

But at the risk of being tedious—for the benefit of those of your readers that may not have the work, (all ought to have it)—I beg leave to make an extract from Prof. Johnston's Lectures, part 2d, p. 428: "Hence, from the proportion of soluble matter present at any one time in the surface soil, we cannot safely pronounce as to the quantity which the whole soil is capable of yielding to the crop that may grow upon it. For when warm weather comes and the surface soil dries rapidly, then by capillary action the water rises from beneath, bringing with it the soluble substances that exist in the subsoil through which it ascends. Successive portions of this water evaporate from the surface, leaving their saline matter behind them. And as this ascent and evaporation goes on as long as the dry weather continues, the saline matter accumulates about the roots of the plants so as to put within their reach an ample supply of every soluble substance which is not really defective in the soil. * * * They (sandy and porous soils) absorb the falling rains with great rapidity, and these carry down the soluble matters as they descend—so that when the soil becomes soaked, and the water begins to flow over its surface, the saline matter, being already buried deep, is in little danger of being washed away.* On the return of dry weather, the water re-ascends from beneath and again diffuses the soluble ingredients through the upper soil."

In conclusion, sir, if any of your respectable class of readers wish to hear any thing more on the subject of "Surface Applications," I refer them to an article in the "Farmer's Register," vol. 9, p. 628, over the signature of S., and to p. 645, where the article is noticed by Mr. Ruffin, also to p. 677 for Mr. Garnett's answer to the same article. I might refer them to other writers that have handled the subject much more ably than has been done by the bungling hand of

Pendleton, S. C., June, 1845. G. S.

*This should encourage us to subsoil our land before planting.

Berkshire Hogs.

MR. CAMAK:—Sir—I promised you a while back that I would give you my method of managing Berkshire hogs to profit. In compliance with my promise, I herewith forward you my prescription, without any other preliminaries than simply to say, I got in possession of some Berkshire hogs about five years ago, and to be sure that I was not humbugged, I procured them of different stocks; which, from their recommendations and appearances, I supposed were all of the choicest breeds. From that time until now I have experimented with them in all sorts of fashions. I have fed them bountifully on all sorts of grains, grasses, peas, potatoes, fruits, vegetables, meal and slops, and I have fed them scantily; I have enclosed them in lots, and I have let them run at large; I have fed them by themselves, and I have fed them with other hogs; but in spite of my best personal efforts, I have lost at least thirty of them to one of my common stock, notwithstanding I have had, all the while, five times as many of the common stock as I have had of the Berkshire. They would die poor, and they would die fat; they were subject to all sorts of diseases, old and complicated, new and simple; they would take the mange, and they would become lousy; they would die suddenly, and they would linger to death.

What to do under the circumstances was of course a subject of much deliberation and inquiry. Had these things happened to the common stock, it would have been a matter of no great surprise; but it was the Berkshire hogs that were thus affected! To suppose them to be a humbug, as the signs seemed to indicate, would be to stake my judgment against the generally received opinion of the people, and the positive declaration of many good men. That wouldn't do: I appealed to the sense of the enlightened to learn the cause. None could tell. I waited on the ignorant to know the reason; but they were ever strangers to the case. Whilst oscillating between the various conjectures of a bewildered mind, and conjuring up schemes to reconcile experience with the opinions and sayings of others wiser and better than myself, I was cheered by the reflection that there was one experiment more to be tried; and that I would try it. I did so; and it acted like a charm. I noticed the precise day on which the sows had pigs; if it was before or after the change or full of the moon, I noted it carefully in my memory; and as soon as the circumstances and age of the pigs would allow of it, I altered all the boars, spayed all of the sows, killed the hermaphrodites and knocked the old hogs in the head.

Judging from the time since this method was adopted, and the effects produced by it upon the stock, I am fully persuaded that this breed will soon pass away, and the sooner the better. Seeing the excellent results produced by this practice upon my hogs, I concluded to extend the benefits of my genius and discovery to my neighbors' stock. To this end, I gave orders to my folks, whenever they saw a stray Berkshire hog on any part of my land, they must hallow 'Berkshire!' as loud as they could squall. On hearing this word, as a signal, they must drop their business of whatsoever kind it might be, hasten to the place whence the signal proceeded, and never stop, hands nor dogs, until they altered or spayed the hog, as the case might be.

Newborn, June, 1845. JOHN W. PITTS.

Wheat Straw, a Substitute for Fodder.

THIS is the season wheat is got out, and I regret to see the straw is thrown out to make manure. I once had a meadow of thirty acres, producing good grass, (feather clover, and a broad leafed blue grass,) all of which made a very fine quality of hay.

To save the trouble of feeding, and to furnish shelter for my cattle, I put forks in the ground, and on them placed poles of such size and at such a distance apart that the cattle could draw

the hay down from between these poles, which were placed, by the height of the forks, so as to admit the cattle freely to walk under the frame, as I will call it. On this frame I stacked my hay.

I stacked wheat straw in the same way, generally on the poorest spots in the field. My cattle were turned in and permitted to feed themselves, and at pleasure, to use the stacks as shelter, of which they soon learned the advantages. I found my cattle would use the stacks of hay as shelter, but would not eat any of the hay, so long as the straw lasted, which proved to me, if they had proper taste, that the straw was more valuable than the hay.

My horses and mules were furnished with hay alone, in the stable, on which they showed health, and usual thrift. This experiment for some years was observed, and regularly this preference was shown for the straw by the cattle; and they improved and looked better while enjoying the feed on straw, than when they were confined to hay alone, which was as soon as the straw was consumed.

I have never tried to feed the straw alone to horses, but I would not hesitate to say, it is worth more than fodder. Try it; save your own straw; it will feed and sustain cattle, horses and mules, and ultimately make manure more valuable than by the slovenly process of throwing out to rot. D. REINHARDT.

Greenville, S. C., June, 1845.

Hints to Advertisers.

MR. CAMAK:—It has occurred to me that a few hints to your advertising friends, Hazard, Denslow & Webster, might not be amiss. The propriety of a purchase frequently depends upon the price of the article desired. I wish to procure a light subsoil plow, and I have heard one of my neighbors also express such a desire. Now if the furrow slice, the depth, and the price of each plow were stated I could easily determine which I should prefer. All this might be added without materially enlarging their advertisement. I would further remark, that a knowledge of the cost of transportation for such articles might facilitate their introduction into the country.

I doubt not that the above named gentlemen would profit by sending a few samples of their plows into the up country. A few such deposited at some suitable place in your town, during the week of your approaching Commencement, would be formidable competitors for a place among the *lions* of the town. A friend could not be *wanting* in your flourishing place, who would cheerfully take the trouble to act as "historian to the" *lions*, and sell them when curiosity was satisfied. If authority was given to make a public trial of them it would be still better.

Your friend, Mr. B. H. Warren, of Augusta, might also have sold several *Leicester bucks*, if he had stated his price for them.

GREENE B. HAYGOOD.

Casulon, Clark county, June, 1845.

Mixing Soils—Inquiries.

MR. CAMAK:—I live in the piny woods and the soil is light and sandy.

Would clay taken from the ponds or river swamp, and put broadcast over a soil of that sort, and plowed in, have any effect to fertilize it or to make it produce good crops?

How would swamp mud do? That, however, is difficult to obtain in large quantities; for directly you get through the mud and come to the clay.

And also, what effect would lime have—say Thomaston lime, such as we can get in Savannah—by putting a spoonful or two in the hill every year at the time of planting?

Respectfully yours, N. ASHLEY.

Ocmulgeeville, Telfair county, June, 1845.

The Fairs—A Suggestion.

MR. EDITOR:—I see by the advertisement in your paper, that the fair of the "Planters' Club of Hancock County," and of the "Agricultural Society of Bowling Green," will take place on the same day. This certainly is in bad taste, as it will render it impossible for one man to exhibit stock at both places. One I know, and there may be others, who would like to exhibit at both fairs. Can you not recommend the Bowling Green Society to make some alteration in the time of holding their fair so as to avoid this clashing? They are the youngest club and ought to yield if either should. Respectfully,

A FRIEND TO THE CAUSE.

Woodville, Greene county, July, 1845.

ESSAY

READ TO THE BURKE COUNTY AGRICULTURAL SOCIETY, *at its first meeting, according to appointment.*

BY PAUL DAVIDSON.

On the importance of our pursuit I shall not dwell for a moment. We all feel it. All acknowledge its use, for not only the welfare, but the very existence of a civilized community depends upon it. Of the necessity of our improving in this our vocation, we ourselves must be the judges. That this necessity exists, you have all acknowledged by subscribing to our constitution.

If there is any one thing more than another, which is cheering to the heart of the true patriot and philanthropist, the real lover of his country and her interest, it is the spirit of inquiry, and improvement in agricultural pursuits, which now seems to pervade almost the whole land. This is truly encouraging, and, in my opinion, is a presage of better things and happier times. If indeed there is any one who does not acknowledge the necessity of improvement in our system of agriculture, he certainly cannot be aware of the position he holds in comparison with agriculturists of a different section of our own country, much less with the more advanced state of the art in certain other countries.

Even if we should admit that we have arrived at the greatest degree of perfection in the cultivation of cotton, it would be but an unprofitable admission, and would prove at once the necessity of our diversifying our pursuits in other branches of agricultural industry, whereby, if we derive no greater profits, we shall become more independent than is possible while we depend upon a single staple for our income, and a foreign market for our necessaries and conveniencies, many of which we can make much cheaper than those can who supply us.

But before we attempt to strike out a new course of pursuit, it will be necessary, to insure success, that we should obtain all the information in our power in regard to the different branches intended to be pursued. Then, with all the lights and guides which ancient experience and modern research have thrown in our way, we may "go ahead" with a good assurance of success. But without this we shall as certainly fail; for we are, many of us, in the condition of a mariner who has been all his life navigating a single sea, and sailing back and forth upon a single track, until want of trade compelled him to navigate other seas, and seek other ports to supply his cargoes. Now, in order to insure safety and success, he must get all the information extant, and procure all the maps and charts which relate to the course of his new route.—Without these precautions he will be in constant danger of being wrecked upon hidden reefs and quicksands. Now the planter who does not take all these precautions, upon commencing a new pursuit, will be in danger of meeting the most disastrous consequences, until the loss of several crops, and the expense of a vast deal of labor shall have taught him, by experience, what he could have learned for a few dollars, or perhaps shillings.

Heretofore, experience has been the only mode of obtaining information upon agricultural subjects. But this, though a sure, is a slow and often expensive mode of arriving at the same results, which the application of analysis will often lead to at once with equal certainty. Modern science and research have taught us that, by means of chemical analysis, we can at once ascertain not only the elements entering into the composition of the plant, but their quantity, and the kind of soil best adapted to its growth and the perfect development of its fruit; and also the kind of manure best adapted to the plant and soil.

Now the facts developed by chemical research always accord with those ascertained by experience—for facts never controvert each other; and to prove this, it is only necessary to cite a case or two which are familiar to all. We all know that wood ashes form the very best manure for a crop of cotton. Now chemical analysis shows us that the cotton plant and its fruit contain potash and lime, the former to a large amount. We further know that the soils best adapted to the raising of cotton, are those which have originally produced a growth of timber indicating that there was a large amount of potash and lime present in the soil, as oak, hickory, dogwood, &c. And on the contrary, pine lands are far less suitable for the perfect development of that plant, and that though upon pine lands can be grown a stem of sufficient size, the fruit is always wanting in a greater or less degree.

We know, from every day's observation, that hard wood timber produces a much greater amount of ashes than the softer woods:—for example, the beech and post oak, than the pine; and also, that their ashes are much richer in the alkalies. Now there are certain other circumstances necessary for a proper soil, yet the presence of a sufficient quantity of the above named materials is absolutely essential. Nor does the fact that some rare spots of pine land are found that produce very good crops of cotton, controvert, in the least, the general rule that cotton grows best on oak and hickory land. For although oak and hickory require a particular soil for their development, yet there is nothing in a soil adapted to their growth, which would prevent the long leafed pine from growing, as it sometimes does on such soils, very luxuriantly, until it is gradually displaced by the oak. Yet the contrary is not true, for oaks can never be produced in perfection upon soils which may be capable of producing a fair growth of pines. In following out this train of observation, we find that when a soil has become exhausted of the proper materials for producing cotton, it will not produce the original growth of oak and hickory; for when an exhausted field is turned out, it shoots up a growth of old field pines, which, you all know, are very deficient in alkalies and earthy matters, and therefore best suited to a soil exhausted of these principles. In fact the old field pine requires so little of potash and lime for its growth, that an old field, after having sustained a crop of that growth for a series of years, accumulates sufficient of these principles, partly by absorption, but mainly, I think, from the liberation of these salts from their insoluble combinations, through the action of the atmosphere and other causes, to render it again comparatively fertile for a few years, when it is again exhausted and again renewed in the same manner.

This theory also explains why soils producing originally different varieties of the same plant, oak for example, does not produce cotton and other crops equally; for every experienced cotton planter in selecting his lands for that staple, will prefer the soil which has originally produced a growth of post oak rather than any other. Now the post oak contains the alkalies and alkaline earth before mentioned in larger proportions than any other species, and therefore indicates a soil rich in these elements of fertility; while lands producing the Spanish red oak are seldom fertile any great length of time. Now any old lady in the country, accustomed to making soap, can tell the difference in these two varieties of oak, as regards the quantity of ashes produced upon burning them. The latter yields a much smaller quantity than the former, and therefore indicates a soil much poorer in these elements. Now what is true in relation to one plant, is true also with all, according to their varieties, and the elements entering into their composition. Wheat and most grains contain, among their component parts, various salts, as the phosphates of lime, (which is the solid part of all bones,) magnesia and soda, or potash. Now it matters not how rich a soil is in vegetable matter and every other substance, if it is deficient in any of these salts it will not produce a perfect development. Nor is the quantity of an element contained in the grain or plant a criterion of its necessity, for although it may enter into the mass as but a very small part of the whole substance, yet it is not the less necessary that it should be present. When we survey the work of the mason and observe the small quantity of lime which he uses in proportion to the mass of the whole fabric, it would almost seem that it could be dispensed with; yet the building would be far from perfect without it. It is just so with plants, and though the inorganic constitutents enter into their composition

in but very minute quantities, they are just as essential to its perfection as the vegetable matter which builds up the mass of the plant.

And it is undoubtedly the lack of some of these elements that causes the rust and blight in wheat in certain localities, although the soil appears rich in all the constituents necessary to build up the frame work of the plant, and produces the stalk in great luxuriance, but not grain, or but very little.

The same is true of the cotton plant; some soils producing a fine plant, as far as size is concerned, and but very little fruit. This is strikingly the case with most pine lands. Here there is evidently sufficient vegetable matter to produce the frame, but a lack of some inorganic constituent to produce a full crop of fruit; whereas the contrary is the case in some of our soils which originally contained the inorganic materials in great abundance, so that there are sufficient of them remaining to produce an abundant crop of fruit, but the material (vegetable matter or humus) to build up the stalk is exhausted, so that although the soil produces much fruit in proportion to the size of the plant, yet the stalk being deficient in size the product is necessarily deficient.

Now the deficiencies in both these cases are to be supplied; and, according to the old method of culture, are to be supplied by an application of the same materials, to wit: the gleanings of the horse lot and the cow pen. These are very good in their place, but the attempt to supply two very different wants by the same material, is, at best, but a quackish application of means.—Would it not be far better to ascertain by analysis the deficiencies to be supplied, and the materials necessary to supply those wants, so that we may be able to apply our labor and capital more properly, by suiting our means to the ends designed, than to continue blundering along, after the old empyrical mode of applying the same means to all ends, whereby we have so often been disappointed in the results.

This is not only the teaching of reason, but also of economy; for by adopting the above plan, we should be able to apply every thing just where it would be most wanted; and as nothing would be misapplied, nothing would be wasted.

Now, my friends, unless we arouse ourselves and shake off the lethargy which binds us to old customs, and cease to be content to carry a rock in one end of the bag to balance the pumpkin in the other end, because our fathers did so, and look into this matter deeply and thoroughly, and take some steps, aye! some long strides, in the improvement of our avocation, we shall be soon left out of sight, in the rear of our more enterprising neighbors, and be reduced to even a greater degree of dependence for our necessities and comforts, than at present. But under the old system we shall soon be reduced to a point that will not enable us to purchase all the little conveniencies which our northern friends are always so ready to furnish us with *while our money lasts*, but when that is gone, credit soon follows. Then, if not before, shall we see the error of our ways, and set about making those improvements which have already placed our neighbors so far before us.

Improve your Lands.

We take the following sensible article (says the Mobile Register,) from an old number of the Alabama State Intelligencer. It was copied very generally by the Southern Press some eight or ten years ago, but it has lost none of its interest, or its applicability to modes of cultivation among our Planters. We think we recognise in it the pen of one of our most intelligent and practical cultivators; one who has done more by precept and example to advance the interests of agricultural and horticultural industry than any man in the State.

If to produce the greatest quantity possible of any article or articles, from a given quantity of land, and in the process of production to increase the fertility of the soil in a great degree, is the acme of agricultural pursuits, it may be fairly advanced that to cultivate a large surface of land, and by the mode of cultivation, for a small production, and with a great destruction of the productive properties of the soil, must be the acme of absurdity.

If there is any available process, that by the additional expense of one half of the additional production, will add one hundred per cent. to the product of labor bestowed on land, the process ought to be adopted for interest's sake; but if the one-fourth left is added to the increase of the productive quality given to the land, it then claims from every rational being who cultivates the soil, an immediate attention. It is astonishing, that the land wearing out so rapidly, as we often see it, does not startle every cultivator, who is but one degree removed from an idiot. If the people of the northern part of the United States, were to go as honestly to work in the destruction of their land, in their mode of cultivation as we do, we should soon hear melancholy news of their situation, in lieu of that agricultural prosperity which their land and labor secures them.

When a farmer in that section of the Union sits down on a tract of land previously worn out by some squatter, (for the breed is not worn out there, nor will it be, as long they hear of a Texas,) with not a foot to "clear" he feels no great uneasiness. He can tell by his mode of proceeding almost precisely the increase of crops he will get and the time it will require to get his land "into heart," for the production of seventy or eighty bushels of corn to the acre; and although he live in the midst of a thick settled country, with not one of the available means of fertilizing his land, which we Southerners have around us, he is easy, while we should think of no other resource than Arab like to move to a "new range." But the Northern farmer who cannot worship cotton, for it is not found amongst his household gods, if he is a judicious cultivator, he goes with all his energies into provision crops—to the production of every article; in this way his situation will admit him to expect rationally a remuneration for his labor, for in this course he secures the thing called manure, of the best kind, and in securing that, he finds the key to agricultural success. This fact allows him to "settle," and he finds he is not compelled to run away from his land every ten years, which has been running away during that period from him, he giving it the start.

But if there is any process of cultivation in the pursuit of which the improvement of the soil will pay for the extra labor, and give to the laboring man the whole extra crop, I must repeat that there must be idiotism in not availing ourselves of it.

Now, in cultivating land, we know that there is a positive expenditure of capital, animals and gear, carriages, provisions and labor. If one half of most of these can be made to produce the same result that the whole usually produce, there is then a positive saving of capital, wear, tear, provisions and labor, of one half.

For instance, say twenty-five acres is made to produce the same amount that fifty usually does, and that one man and one horse is employed in the cultivation; the capital expended on one man and one horse, a set of gears, seed for twenty-five acres, saving of the production, cleaning, clearing, fencing, and keeping up the enclosure, &c. &c., is actually saved.

And if the planter's resources enable him to work the fifty acres, as it ought to be, and to obtain the production for his labor that he ought to obtain, the conclusion is doubly conclusive in favor of the better or more productive system. For in spite of ignorance, intentional or real, it remains a truth strong as holy writ, that twenty-five acres of manured or enriched land are as easily tended as the same number of acres of a *caput mortuum* or impoverished soil.

That a judicious manuring system would bring about the result contended for, is as certain as that there are a Northern and Southern section of the Union.

If these views are correct, then it follows that to insure a successful agricultural pursuit, manure is almost every thing, and the mode of making it, to the greatest advantage, is to the planter of incalculable importance. In the whole circle of common sense, no fact is better established than that if you will take an acre of land, that will produce ten bushels of corn to the acre in its natural state, and manure it, the product will as readily become thirty. Yet if you will look at it, the quantity of "stuff," and actual manure, wasting around the plantations, and especially in the lanes on almost every plantation in the country, you would be obliged to conclude that idiots were quite common, or that this fact is not believed, or that it was not known.

But the fact still remains that land can be made to yield three, nay four times the quantity of many agricultural productions, by a judicious application of manure, combining the materials judiciously that compose it. From land that would not give more than ten bushels of corn per acre, I have grown fifty, with the aid of cotton seed alone. PLANTER.

The Dairy.

From the Salem Gazette.

We extract from the report and statements, presented by the committee of the Essex Agricultural Society, on the dairy, such portions as will be most interesting to our readers:

The committee on the dairy, in presenting their report, would remark that the first prerequisite in making good butter, is to have good cows. And to be sure in this respect, every farmer should test the value of each cow by milking and preserving her milk separately, and noting carefully the quantity required to make a pound of butter. By a very little attention in this way, it may be readily ascertained whether a cow is worth keeping for dairy purposes. Cases have occurred where a cow has been kept for years with several others and their milk put together; on using it separately, it was found that butter could not be made from it. Thus, for the want of attention in this respect, much loss may be sustained. There are undoubtedly many cows kept which add little or nothing to the value of the dairy.

The kind and quantity of salt used, is of much consequence. The Liverpool bag salt should be rejected; it contains impurities, and will not preserve butter. Rocksalt perfectly pulverized, and three-fourths of an ounce used to a pound of butter, will preserve it well.

Process of making butter by those who gained the Society's Premiums.

By Geo. W. Dodge.—The milk is strained into tin pans, where it stands from thirty-six to forty-eight hours, when it is skimmed and the cream put into tin pails, standing on the bottom of a cool cellar. A little salt is added to the cream which is frequently stirred. We churn twice a week. When the butter comes, the buttermilk is thoroughly worked out, and the butter salted with an ounce to the pound. After twenty-four hours it is again worked and weighed.

By Mrs. Abi Worcester.—The cream was churned twice a week, then the butter was washed in cold water. One ounce of fine butter salt was used to one pound of butter, well-worked in. After it had remained twenty-four hours, it was worked over and packed down solid in a stone pot and covered with strong brine.

By Paul Pillsbury.—The milk is strained into tin pans and stands thirty-six hours. The cream is then taken off and put into a tin firkin, and kept until it is ready to be churned, which is twice a week. The butter is well rinsed in cold water and then salted with one ounce of salt to a pound of butter. In about twenty-four hours it is worked again and packed down and kept on the bottom of the cellar, covered with fine salt. The feed of the cows was a common pasture.

By Allen W. Dodge.—Treatment of milk and cream before churning: Strain the milk in tin pans, place them in a cool cellar for the cream to rise; when sufficiently risen, which will be according to the weather, separate the cream from the milk, and the day previous to churning lower the cream, in tin pails or cans, into a well, in order to become cool. By this means, the butter will come of a hard consistency, and no

difficulty experienced in working it thoroughly.

Mode of churning: Rinse the churn with cold water over night. The churn used is Galt's —various other kinds have been tried, such as the barrel-churn and rocking-churn, but with less favorable results. The time occupied in churning, when the cream is cold, is greater than if it was not subjected to the process of cooling, but the quality and condition of the butter amply repay for the time and labor expended upon it. Churn once a week.

The method of freeing the butter from the milk is by thoroughly working the butter with the hands. Rinsing it with cool water in the churn, we have seldom practised, from the conviction that the butter is injured by this process. The day after being worked over, it is put into lumps of one pound each, for market.

Salting of the butter: Use the ground rock salt, and salt to suit the taste. Add no saltpetre, sugar, or other substances.

By Nathaniel Felton.—The milk is strained into tin pans; it stands from thirty-six to forty-eight hours in a cool cellar, when the cream is taken off, put into tin pails, and stirred every day. We churn once a week; during the warmest weather the cream is placed in the well about twelve hours before churning. After it is churned the buttermilk is thoroughly worked out, and the butter is salted with three-quarters of an ounce to the pound. After standing about an hour it is again worked and weighed, each pound separately.

By Benjamin Boynton.—The milk is strained into tin pans. It stands forty-eight hours in a cool cellar, when the cream is taken off, put into a pot, and stirred once a day. We churn once a week. After the butter is churned the buttermilk is turned from it, and water is added twice, and churned to separate the buttermilk from it. One ounce of salt is used to a pound of butter, which is worked twice after.

From the Mobile Daily Advertiser.

Raising Stock.

In the present depressed condition of the planting interest in Alabama, it is astonishing that the farmers do not direct more of their attention to the raising of stock. There is no portion of the United States better calculated for various kinds of stock than Alabama. Horses, mules, cattle, sheep, all thrive well, and our mild climate is more congenial to the *hog*, particularly, than the cold west or north. We have more facilities for raising hogs than Kentucky. They can be raised in South Alabama with less labor and less expenditure. Will this be doubted by our farmers, or denied by the people of the northwest? If so, I trust that some of our wealthy farmers will make the experiment, and it will be found that fifty hogs can be raised in Alabama with as little labor and expenditure as thirty in Kentucky. Let us see what are the facilities of the two sections of country:—Kentucky has her corn, artichokes, oats, rye and grass pastures—while Alabama has her corn, peas, artichokes, oats and rye for pastures, equalling the advantages of Kentucky. Alabama produces in addition, the ground-pea and sweet potatoe, which gives an advantage over all the products of Kentucky as food for hogs. Let us now estimate the value and profits of a farm in the two sections of country employing ten hands—the farm stocked for operation.

In *Kentucky* it would require a landed property of 326 acres, which would cost at $15 per acre, 4,875 dollars. The ten hands would cost five thousand dollars. Capital invested, nine thousand eight hundred and seventy five dollars. In this farm there would be three hundred acres of open land, twenty-five remaining wood for convenience. The three hundred acres of improved land would be cultivated in the following proportions: fifty acres in corn, one hundred and twenty-five in oats and rye, one hundred and twenty-five in clover and blue grass, and twenty in artichokes. This would be the labor of ten hands, which would only provide food sufficient to raise three hundred hogs of one year old. The three hundred acres of blue glass, clover, oats and rye would receive 300 pigs and pasture them from the 1st of May until the 1st of October. It would then take all the artichokes and the corn that would be made to feed the three hundred hogs from the 1st October to the 1st May—seven months, (part of the corn having to be fed to the pigs while on pasture.) The hogs now one year old would weigh one hundred and fifty pounds each, and would make 4,500 pounds of pork, which at $2 50 cents per hundred pounds, would bring to the owner $1,122, sold in Kentucky.

In *Alabama* it would require a landed property of the same number of acres as that of Kentucky. Let us now see if there is any difference in the profits of the capital invested. The 325 acres of land calculated for a farm of this description can be purchased in Alabama at $8 dollars per acre, which would make a cost of twenty-six hundred dollars. The ten negroes cost the same as in Kentucky—five thousand dollars. The cost of the land and negroes in Alabama would be seven thousand six hundred dollars—2,750 dollars less than the outfit in Kentucky. Of the three hundred and twenty-five acres, there would be three hundred acres in culture—forty acres in corn and cow peas, one hundred and twenty-five acres in sweet potatoes, twenty-five acres in ground peas, and one hundred in rye and oats. This would furnish food sufficient for seven hundred head of hogs. The twenty-five acres in ground peas would receive seven hundred pigs the 1st of September, and furnish them with food for two months, ending on the first of November. The one hundred and twenty-five acres in sweet potatoes would yield, at two hundred and fifty bushels per acre, thirty one thousand two hundred and fifty bushels, which would alone feed the seven hundred head of hogs one year, allowing four quarts per day for each hog, which would be more than sufficient food for them one year. The corn, rye and oats would be a reserve, and the Alabama farm of three hundred acres in cultivation, would yield seven hundred head of hogs of one year old, weighing one hundred and fifty pounds each—making one hundred and five thousand pounds of pork, which at three dollars per hundred, would bring to the owner three thousand one hundred and fifty dollars. Showing a proceed of two thousand and twenty-eight dollars more than the farm in Kentucky, with a capital of two thousand seven hundred and fifty dollars less than was employed in Kentucky!

The above is made upon the supposition that the hogs are to be kept in an enclosure, and not suffered to run at large, to be dependent entirely on the product of the farm for sustenance. I have made the above statements upon my own experience and information. The subject will be continued. ALABAMA.

Horticulture.

BY MRS. LYDIA H. SIGOURNEY.

If the admiration of the beautiful things of nature has a tendency to soften and refine the character, the culture of them has a still more powerful and abiding influence. It takes the form of an affection; the seed which we have nursed, the tree of our planting, under whose shade we sit with delight, are to us as living, loving friends. In proportion to the care we have bestowed on them, is the warmth of our regard. They are also gentle and persuasive teachers of His goodness, who causeth the sun to shine, and the dew to distil; who forgets not the tender buried vine amid the snows and ice of winter, but bringeth forth the root long hidden from the eye of man, into vernal splendor, or autumnal fruitage.

The lessons learned among the works of nature are of peculiar value in the present age. The restlessness and din of the railroad principle which pervades its operations, and the spirit of accumulation which threatens to corrode every generous sensibility, are modified by the sweet friendship of the quiet plants. The toil, the hurry, the speculation, the sudden reverses which mark our own times, beyond any which have preceded them, render it particularly salutary for us to heed the admonition of our Saviour, and take instruction from the lilies of the field, those peaceful denizens of the bounty of heaven.

Horticulture has been pronounced by medical men, as salutary to health, and to cheerfulness of spirits; and it would seem that this theory might be sustained, by the happy countenances of those who use it as a relaxation from the excitement of business, or the exhaustion of study. And if he, who devotes his leisure to the culture of the works of nature, benefits himself—he who beautifies a garden for the eye of the community, is surely a public benefactor. He instils into the bosom of the man of the world, panting with the gold fever—gentle thoughts, which do good like a medicine He cheers the desponding invalid, and makes the eye of a child brighten with a more intense happiness. He furnishes pure aliment for that taste which refines character and multplies simple pleasures. To those who earn their substance by laboring on his grounds, he stands in the light of a benefactor. The kind of industry which he promotes, is favorable to simplicity and virtue. With one of the sweetest poets of our native land, we may say,

> "——Praise to the sturdy spade,
> And patient plow, and the shepherd's simple crook,
> And let the light mechanic's tool be hailed
> With honor, which increasing by the power
> Of long companionship, the laborer's hand,
> Cuts off that hand, with all its world of nerves,
> From a too busy commerce with the heart."

Cribbing, or Crib-Biting.

As we have had a number of communications on this subject, we give our readers an extract from the celebrated Youatt, whose book on "the horse," edited by J. S Skinner of Baltimore, is a valuable production. Youatt does not seem to consider this cribbing a disease, but a habit rather, though he says, "the cribbing horse is more subject to the colic than other horses, and to a species difficult of treatment and frequently dangerous."

He says, "It is one of those tricks which are exceedingly contagious. Every companion of the crib-biter, in the same stables, is likely to acquire the habit, and it is the most inveterate of all habits. The edge of the manger will in vain be lined with iron, or with sheepskin covered with tar or aloes, or any other unpleasant substance.

"In defiance of the annoyance which these may occasion, the horse will persist in his attack on the manger. A strap buckled tightly round the neck by compressing the windpipe is the best means of preventing the possibility of this trick, but the strap must be constantly worn, and its pressure is too apt to produce a worse affliction, viz., an irritation in the windpipe, which terminates in roaring.

"Some have recommended turning out for five or six months, but this has never succeeded except with a young horse, and then rarely.—The old crib-biter will employ the gate for the same purpose as the edge of his manger, and we have often seen him galloping across a field for the mere object of having a gripe at a rail—Medicine will be altogether thrown away in this case.

"The only remedy is a muzzle with bars across the bottom sufficiently wide to enable the animal to pick up his corn and to pull his hay, but not to grasp the end of the manger. If this is worn for a considerable period, the horse may be tired of attempting that which he cannot accomplish, and for a while forget the habit, but in a majority of cases the desire of crib-biting will return with the power of gratifying it.

"The causes of crib-biting are various, and some of them beyond the control of the proprietor of the horse. It is often the result of imitation, but it is more frequently the consequence of idleness. The high fed and spirited horse must be in mischief if he is not usefully employed. Sometimes, but we believe not often,

it is produced by partial starvation whether in a bad straw-yard or from unpalatable food. An occasional cause of crib-biting is the frequent custom of grooms, even when the weather is not severe, of dressing them in the stable. The horse either catches at the edge of the manger, or at that of the partition on either side, if he has been turned, and thus he forms the habit of laying hold of these substances on every occasion."

Agriculture.

It has been well said that he who has dominion over an acre of land, and rescues it from barrenness, and covers it with a smiling harvest, has more of virtuous self-applause than the conqueror of large territories, laid waste and desolate. The honorable occupation of cultivating the soil, however, appears to have but few charms for some of the present wise generation, even among those who, from early habits and education, should be well fitted for the employment.

There is too great a desire to become merchants, traders, or speculators; and hence our large cities are at times overrun with persons in the "mercantile line," forsooth—who are every way unqualified for such pursuits; and even if they are qualified for such undertakings, the trade of the country is inadequate to the support of such numbers, as would willingly turn their back upon the farm, and embark on the sea of wild speculation, or flee from a life of *manual labor*.

This is an evil which requires a remedy, and the remedy must be found in the farmers themselves. They should appreciate the blessing of an Agricultural life, and teach their sons and daughters to revere it—to love it as the occupation which is best calculated to develope the excellence of human nature, and secure the happiness of human beings.

There is no error so pernicious, as that of sending young men, fresh from the country, pure in principles and inexperienced, to reside in a populous city, and become familiar with its pleasures, its vices, and its extravagances. What inducement can an honest farmer *have*, thus to banish his children from independence, industry and comfort! I have already said, that of all the characters of which our country can boast, there is none more elevated than a well-informed and sensible farmer—one who has looked into books—who knows the world, his country, and its laws.

It is pleasant to see such a man holding the plow, or manfully swinging the scythe, or plying the flail, in order to cull the rich treasures of Ceres. And when his labors require rest—see him, reclining beneath a shady tree, or seated on a bundle of grain—talk of the ancient Republics of Greece and Rome—detail historical incidents—and expatiate on the government and institutions of his own country. Such a man is useful to himself and a treasure to the nation to which he belongs. If we change the scene, we shall perhaps find him in the halls of legislation, exercising his practical good sense, to allay the fury of heated politicians—aiding to give laws to the State—and firmly sustaining the principles of public policy, which are suggested by a well-disciplined mind, and a keen sense of duty.

I can hardly conceive how a parent can be willing that his son should forego such a life of usefulness, and send him to a large city, to pass a life of indolence—exposed on every hand to temptation—without a hope of profit or advancement. And yet we shall find that many of the shops and retail stores in our cities, are filled by young men—the sons of farmers, who cherish a contempt for the occupation of their fathers—and who, eager to escape from a life of salutary labor, abandon a certain road to character and independence—and shuffle along through the world without any prospect of being useful to society, or beneficial to themselves.—[*Mr. Sleeper's Address at Worcester.*

CONTENTS OF THIS NUMBER.

ORIGINAL PAPERS.

SELECTIONS, EXTRACTS, &c.

The Southern Cultivator

Is published on the first of every month, at Augusta, Ga.

J. W. & W. S. JONES, PROPRIETORS.

EDITED BY JAMES CAMAK, OF ATHENS, GA.

TERMS.—ONE DOLLAR A YEAR.

1 *copy, one year*,..... $1 00 | 25 *copies, one year*,..$20 00
6 *copies*, " ..... 5 00 | 100 *copies*, " .. 75 00.

[All subscriptions must commence with the volume.]

THE CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to Agriculture, will be inserted for ONE DOLLAR for every square of ten lines or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞ POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS, MUST BE POST PAID, and addressed to JAMES CAMAK Athens, Georgia.

VOL. III. AUGUSTA, GA., SEPTEMBER, 1845. No. 9.

HORTICULTURAL OUTLINE.

AN OUTLINE OF THE FIRST PRINCIPLES OF HORTICULTURE: By JOHN LINDLEY, F.R.S., &c., &c., Professor of Botany in the University of London, and Assistant Secretary of the Horticultural Society.—[CONCLUDED.]

XII. PERSPIRATION.

299. It is not, however, exclusively by the action of light and air that the nature of sap is altered. Evaporation is constantly going on during the growth of a plant, and sometimes is so copious, that an individual will perspire its own weight of water in the course of 24 hours.

300. The loss thus occasioned by the leaves is supplied by crude fluid, absorbed by the roots, and conveyed up the stem with great rapidity.

301. The consequence of such copious perspiration is the separation and solidification of the carbonized matter that is produced for the peculiar secretions of a species.

302. For the maintenance of a plant in health, it is indispensable that the supply of fluid by the roots should be continual and uninterrupted.

303. If any thing causes perspiration to take place faster than it can be counteracted by the absorption of fluid from the earth, plants will be dried up and perish.

304. Such causes are, destruction of spongioles, an insufficient quantity of fluid in the soil, an exposure of the spongioles to occasional dryness, and a dry atmosphere.

305. The most ready means of counteracting the evil consequences of an imperfect action of the roots is by preventing or diminishing evaporation.

306. This is to be effected by rendering the atmosphere extremely humid.

307. Thus, in curvilinear iron hot-houses, in which the atmosphere becomes so dry in consequence of the heat, that plants perish, it is necessary that the air should be rendered extremely humid, by throwing water upon the pavement, or by introducing steam.

308. And in transplantation in dry weather, evergreens, or plants in leaf, often die, because the spongioles are destroyed, or so far injured in the operation as to be unable to act, while the leaves never cease to perspire.

309. The greater certainty of transplanting plants that have been growing in pots is from this latter circumstance intelligible;

310. While the utility of putting cuttings or newly transplanted seedlings into a shady, damp atmosphere, is explained by the necessity of hindering evaporation.

XIII. CUTTINGS.

311. When a separate portion of a plant is caused to produce new roots and branches, and to increase an individual, it is a cutting.

312. Cuttings are of two sorts—cuttings properly so called, and *eyes*. (319.)

313. A cutting consists of an internodium, or a part of one, with its nodus and leaf-bud.

314. When the internodium is plunged in the earth it attracts fluid from the soil, and nourishes the bud until it can feed itself.

315. The bud, feeding at first upon the matter in the internodium, gradually elongates upwards into a branch, and sends organized matter downwards, which becomes roots.

316. As soon as it has established a communication with the soil, it becomes a new individual, exactly like that from which it was taken.

317. As it is the action of the leaf-buds that causes growth in a cutting, it follows that no cutting without a leaf-bud will grow;

318. Unless the cutting has great vitality and power of forming adventitious leaf-buds (119,) which sometimes happens.

319. An eye is a leaf-bud without an internodium

320. It only differs from a cutting in having no reservoir of food on which to exist, and in emitting its roots immediately from the base of the leaf-bud into the soil.

321. As cuttings will very often, if not always, develope leaves before any powerful connection is formed between them and the soil, they are peculiarly liable to suffer from perspiration.

322. Hence the importance of maintaining their atmosphere in an uniform state of humidity, as is effected by putting bell or other glasses over them.

323. In this case, however, it is necessary that if air-tight covers are employed, such as bell glasses, they should be from time to time removed and replaced, for the sake of getting rid of excessive humidity.

324. Layers differ from cuttings in nothing except that they strike root into the soil while yet adhering to the parent plant.

325. Whatever is true of cuttings is true of layers, except that the latter are not liable to suffer by evaporation, because of their communication with the parent plant.

326. As cuttings strike roots into the earth by the action of leaves or leaf-buds, it might be supposed that they will strike most readily when the leaves or leaf-buds are in their greatest vigor.

327. Nevertheless, this power is controlled so much by the peculiar vital powers of different species, and by secondary considerations, that it is impossible to say that this is an absolute rule

328. Thus Dahlias and other herbaceous plants will strike roots freely when cuttings are very young; and Heaths, Azaleas, and other hard wooded plants, only when the wood has just begun to harden.

329. The former is, probably, owing to some specific vital excitability, the force of which we cannot appreciate; the latter either to a kind of torpor, which seems to seize such plants when their tissue is once emptied of fluid, or to a natural slowness to send downwards woody matter, whether for wood or not, which is the real cause of their wood being harder.

330. If ripened cuttings are upon the whole the most fitted for multiplication, it is because their tissue is less absorbent than when younger, and that they are less likely to suffer either from repletion or evaporation.

331. For, to gorge tissue with food, before leaves are in action to decompose and assimilate it, is as prejudicial as to empty tissue by the action of leaves, before spongioles are prepared to replenish it.

332. For this reason pure silex, in which no stimulating substances are contained (silver sand,) is the best adapted for promoting the rooting of cuttings that strike with difficulty.

333. And for the same reason, cuttings with what gardeners call a *heel* to them, or a piece of the older wood, strike root more readily than such as are not so protected. The greater age of the tissue of the heel renders it less absorbent than tissue that is altogether newly formed

334. It is to avoid the bad effect of evaporation that leaves are usually for the most part removed from a cutting, when it is first prepared.

XIV. SCIONS.

335. A scion is a cutting (311,) which is caused to grow upon another plant, and not in earth.

336. Scions are of two sorts, scions properly so called, and *buds* (354.)

337. Whatever is true of cuttings is true also of scions, all circumstances being equal.

338. When a scion is adapted to another plant, it attracts fluid from it for the nourishment of its leaf-buds until they can feed themselves.

339. Its buds thus fed gradually grow upwards into branches, and send woody matter downwards, which is analogous to roots.

340. At the same time the cellular substance of the scion and its *stock* adheres (19,) so as to form a complete organic union.

341. The woody matter descending from the bud passes through the cellular substance into the stock, where it occupies the same situation as would have been occupied by woody matter supplied by buds belonging to the stock itself.

342. Once united, the scion covers the wood of the stock with new wood, and causes the production of new roots.

343. But the character of the woody matter sent down by the scion over the wood of the stock being determined by the cellular substance, which has exclusively a horizontal developement, (73,) it follows that the wood of the stock will always remain apparently the same, although it is furnished by the scion.

344. Some scions will grow upon a stock without being able to transmit any woody matter into it; as some Cacti.

345. When this happens, the adhesion of the two takes place by the cellular substance only, and the union is so imperfect that a slight degree of violence suffices to dissever them.

346. And in such cases the buds are fed by their woody matter, which absorbs the ascending sap from the stock at the point where the adhesion has occurred; and the latter, never augmenting in diameter, is finally overgrown by the scion.

347. When, in such instances, the communication between the stock and the scion is so much interrupted that the sap can no longer ascend with sufficient rapidity into the branches, the latter die; as in many peaches.

348. This incomplete union between the scion and its stock is owing to some constitutional or organic difference in the two.

349. Therefore care should be taken that when plants are grafted on one another, their constitution should be as nearly as possible identical.

350. As adhesion of only an imperfect nature takes place when the scion and stock are, to a certain degree, dissimilar in constitution, so will no adhesion whatever occur when their constitutional differences are very decided.

351. Hence it is only species very nearly allied in nature that can be grafted on each other.

352. As only similar tissues will unite (19,) it is necessary in applying a scion to the stock, that similar parts should be carefully adapted to each other; as bark to bark, cambium to cambium, and alburnum to alburnum.

353. The second is more especially requisite,

because it is through the cambium that the woody matter sent downwards by the buds must pass; and also because cambium itself, being organizing matter in an incipient state, will more readily form an adhesion than any other part.

354. The same principles apply to *buds*, which are to scions precisely what eyes (319,) are to cuttings.

355. Inarching is the same with reference to grafting that laying (324,) is with reference to striking by cuttings.

356. It serves to maintain the vitality of a scion until it can form an adhesion with its stock; and must be considered the most certain mode of grafting.

357. It is probable that every species of flowering plant, without exception, may be multiplied by grafting.

358. Nevertheless, there are many species and even tribes that never have been grafted.

359. It has been found that in the vine and the walnut this difficulty can be overcome by attention to their peculiar constitutions; and it is probable that the same attention will remove supposed difficulties in the case of other species.

XV. TRANSPLANTATION.

360. Transplantation consists in removing a plant from the soil in which it is growing to some other soil.

361. If, in the operation, the plant is torpid, and its spongioles uninjured, the removal will not be productive of any interruption to the previous rate of growth.

362. And if it is growing, or evergreen, and the spongioles are uninjured, the removal will produce no further injury than may arise from the temporary suspension of the action of the spongioles, and the noncessation of perspiration during the operation.

363. So that the transplantation may take place at all seasons of the year, and under all circumstances, provided the spongioles are uninjured.

364. This applies to the largest trees as well as to the smallest herbs.

365. But as it is impossible to take plants out of the earth without destroying or injuring the spongioles, the evil consequences of such accidents must be remedied by the hindrance of evaporation.

366. Transplantation should, therefore, take place only when plants are torpid, and when their respiratory organs (leaves) are absent; or, if they never lose those organs, as evergreens, only at seasons when the atmosphere is periodically charged with humidity for some considerable time.

367. Old trees in which the roots are much injured, form new ones so slowly, that they are very liable to be exhausted of sap by the absorption of their very numerous young buds before new spongioles can be formed.

368. The amputation of all their upper extremities is the most probable prevention of death; but in most cases injury of their roots is without a remedy.

369. Plants in pots being so circumstanced that the spongioles are protected from injury, can, however, be transplanted at all seasons, without any dangerous consequences.

Good and Bad Farming.

From the Western Cultivator.

MR. HATCH:---On presenting myself as a candidate for admission into the society of your numerous and able correspondents, I have concluded to conform to the fashion of the age, and give a bit of my "experience," as a sample of my qualifications for the place desired. It runs as follows:

In one of my excursions in the central part of this State during the past summer, I met with a little incident, that has since had a very beneficial effect on my mind, and I will tell it to your readers, hoping that it may have the like effect on them.

'Twas a hot sultry day in the mouth of August. I had travelled long and hard, through an open country, that was here and there interspersed with large, ragged looking farms, with broken down fences, slovenly cultivation, roofless hovels, old hats, coats, frocks and all sorts of rags protruding from the broken windows, with dirty, ignorant-looking little urchins, in almost every state, approaching to entire nudity, playing along the road. All betokened shiftlessness and improvidence in the extreme, which formed a sad contrast to some in the land that gave me birth, and caused me to look forward with some anxiety for a place where I might have a reasonable prospect of procuring a respectable meal, and enjoying an hour's agreeable discourse with some of my fellows.

About 1 o'clock P. M. I espied at a short distance to the right of the road, a small cottage looking building, standing in an improvement of some thirty or forty acres, surrounded, divided and subdivided, with neat, substantial picket fences, with a gate in front of the house, opening into an ample door-yard, the first gate and door-yard I had seen that day. Along the entire line of fence stood, some ten feet apart, a row of locust, balm of gilead and other trees, of four or five years thrifty growth. A strip of the same kind, about twenty rods long and ten wide, was planted on the west side of the house and garden, forming a thrifty little grove, that would soon shield the owners alike from the chilly blasts and summer's sun; with a small orchard of different kinds of fruit trees large enough to bear, on the next side of the house. All of which I discovered in half the time that it takes me to write it, and it formed such a noble contrast to the cheerless abodes that I had just passed, I could not resist the temptation to dismount, and apply for refreshment. I walked up to the passage in front of the house, in the cool shade of which sat a man about thirty years of age, reading a periodical of some kind, by whom I was received with a frankness and urbanity of manners, that plainly bespoke intelligence and good breeding.

Old grey was soon deposited in a small frame horse barn, the cool shade of which, with the sweet smelling new made hay must have made him think of "the days of Auld Langsyne." Returning to the house, I was soon engaged in agreeable conversation with my host and his accomplished lady, (that the hearty meal scarce interrupted,) in the course of which I learned the following facts.

About six years previous (being just married) and without much experience in agricultural matters, he emigrated to that place, purchased eighty acres of land, and commenced making a farm, amid the evil prophesyings of nearly all his neighbors. Some thought him too inexperienced in such matters; some thought his farm too small---for, said they, "there's no use of trying to gain a living off of less than two hundred acres, for with all our labor and experience we can scarce make both ends meet, so he will starve to death on that little patch, that's certain." Others thought he spent too much time in reading, for, said they, "although he is up in tolerable season in the morning, yet he spends all the middle of the day with his books, he is a complete book worm." Others thought he spent too much time in setting out trees, working in the garden, making flower beds, &c. For, said they, "its no use planting an orchard, it won't be large enough to bear much in our day, and if it would I don't believe this country is very good for fruit; but at all events, them are locust, cotton wood, balm of gilead, &c., will be of no use, for they wont never bear nothing no how." In short, they looked upon his maiden attempt at Horticulture as supremely ridiculous.

But notwithstanding all this, he had succeeded beyond his most sanguine anticipations, and now enjoyed comfort and competence. For, said he, "although I have under cultivation but about forty acres, that is as much as I can tend well, and I really think that I get more profit from that than my neighbors do from four times as much, cultivated in their careless way. And as to the orchard, by keeping it clean and well loosened around the trees, it is now beginning to bear, though only four years old; I have also plenty of cherries, plums, peaches, currants, gooseberries, raspberries, &c.; and my neighbors begin to *relish* a visit with us once in a while, to partake of such varieties in these parts. They begin to suspect too, that this country is tolerable good for fruit, *if it was only planted;* and some of the more enterprising ones are thinking seriously of planting orchards of their own, after having now lost some ten years, since the settlement of their farms.

"Then there are the ornamental trees, that I was to get no profit from. By loosening the earth around the roots twice each season, they now take care of themselves and afford a tolerable shade to my calves and sheep in the middle of the day, while the animals generally hereabouts are puffing and blowing the little flesh away, that they have been able to accumulate in feeding time. Then they cost so little, I have planted by odd spells, when I should have been doing little else, and I would not now take a silver dollar apiece for them, though they never cost over five cents. In fact I cannot believe there is another improvement on my farm, that pays so well for so small an investment, as these same trees."

Thus he probably would have gone on for half an hour at least, about his hen-roosts, piggeries, sheds, stables, gates, gardens, &c., &c. Each of which occupied its appropriate place, had not my impatience to know how he came to have all this knowledge, interrupted him. He at once stepped to a small book shelf, and laid his hand on a large pile of agricultural papers, among which the Western Cultivator and Prairie Farmer occupied a conspicuous place.

"These," said he, "are the direct source of my success. I came here as ignorant as any 'sucker' in all this Egyptian part of our State, and probably should have remained so, had not a judicious friend advised me to take two or three well conducted agricultural papers. I took them, read them, and practised from their suggestions; by which I have stored my mind with much valuable information. During rainy days, long winter evenings and the middle of hot days in summer, (while my neighbors have spent their time in idleness and jesting of my folly,) I have been taking lessons from the best agriculturists of the age, which, aside from the pleasure, has proved a valuable investment in dollars and cents, and while they have been delving with an old-fashioned hoe or axe, or scratching their ground with a plow ill adapted to the soil, the information thus acquired has enabled me to procure better articles, that have saved much time, patience and profit.

In short, for all that I have around me that is not common in these parts, I am indebted to these papers, for they not only give the needed practical information, but what is worth full as much, they are a great incentive to action."

Well, well, thought I, if this is the book farming against which I have heard so much said, would to God all were book farmers in the land; and I resolved forthwith to become one myself.

B. SMITH.

MAD ITCH.—The effect of cattle following hogs that are fed on green corn, cut up and thrown to them when in the roasting-ear state, is very fatal. The hogs will chew the corn-stalk and extract all the sap, and then throw it out. These fibres, thus thrown out, with the sap extracted, will be eaten voraciously by the cattle. It contains no nutriment to give fermentation to enable the animal to ruminate; and it thus lays dormant and inactive in the manifolds or stomach; becomes perfectly compact and undigestable—creates a fever, and in the end destroys the animal. "I have lost many fine cattle in this way," says Gov. Vance of Ohio, "and have never been able to save one thus afflicted. The entire symptoms are similar to what is called the 'mad itch,' which I have no doubt is created by the same cause, by taking in indigestible matter, incapable of fermentation, and rumination."

Crops require to be Fed as well as Animals.

From the Ohio Cultivator.

In the first settlement of this country, the domestic animals found food growing spontaneously in the prairies and forests, and they lived almost entirely without the aid of their owners. As the country became more populous, and the animals had greatly increased, this spontaneous food became exhausted, and they had to be fed by the hand of man.

When the soil was first reclaimed from the forest, the *crops* obtained *their* food for a number of years from the abundance of *vegetable* matter which had been accumulating in the soil, as well as from the inorganic substances which had been brought there by natural causes. But in a few years, by a constant drain upon the soil, without making any recompense, this spontaneous food which nature had provided, has become principally exhausted; and it is now as much the interest of the farmer to feed his crops as it is to feed his animals.

"I do feed my crops," says the *Practical Farmer*—"I haul out stable manure and straw, and I sometimes plow in clover, and put my land in first rate order before I sow my crops."

"Very well," says *Science*, "this is all right, so far as it goes, and I grant one in a hundred may do this; but I should like to be able to make this statement in 'inverse proportion,' that there shall be but one in a hundred who does *not* do it."

"But, Mr. *Practical Farmer*, there is another matter connected with feeding your crops that I wish to press upon your attention, which is this—It is as important to feed your *crops* with the kind of food *most suitable* to their 'digestive organs,' as it is that of animals. Did you ever think of this? We do not feed hogs on hay; neither do we give pork to our horses; but we are, nevertheless, careful to give *enough* to keep them alive, and to cause the animals to thrive and increase, and, at the same time, we avoid giving them so *much* as to surfeit or founder them."

"After all the pains I take," says the *Practical Farmer*, "I cannot raise good wheat; when I sow it on my land without manure, it is struck with rust; the berry shrivels, and I do not get half a crop. And then I go to carting on manure, and my wheat all goes to straw, falls down flat on the ground, and has no grain worth the labor of saving; and so I turn my hogs into the field to get what few grains they can find. It is useless for me to try to raise wheat on my farm; it is either too rich or too poor. If I put on manure the straw grows too rank, and it is too weak to stand up; if I sow without manure, the *heat* and *moisture* strike it with rust. I must go to raising some other crop."

"Stop, neighbor," says *Science*, "here I have a book that will tell you something about raising wheat. I think it is probable that you have been feeding your hogs on hay, or else you have been giving pork to your horses."

Prac. Far. Och! go away with your *book*. Do you think I want any of your *book farming* about me? I have been a *practical farmer* all my life, and in early times I used to raise the best wheat in the country, without *manure* or *books* either. Do you think that I dont know how to raise wheat?

Science. Will you read it?

Prac. Far. No. It is so seldom I read that it is quite a task for me to read a book.

Science. Well, will you listen while I read?

Prac. Far. I have not time to stay long, but I have no objection to hearing you read a little; it won't *cost anything*, will it?

Science. If you will listen attentively, I will read you a few lines with pleasure:—From each acre yielding 25 bushels of wheat, there is extracted from the soil, in the grain, 3.3 pounds of *potash*, and in the straw 0.6 of a lb.*

Prac. Far. What! does wheat contain potash?

Science. Yes And the 25 bushels of wheat will also take from the soil in the grain, 3.5 pounds of *soda*, and the straw 0.9 of a pound.

Prac. Far. Ah! does wheat contain soda too?

Science. Such an acre of wheat will also take from the soil in the grain, 1.5 pounds of *lime*, and in the straw 7.2 pounds.

Prac Far. Oh, yes! I have heard of people putting lime on their land, but I never thought enough of it to try it myself.

Science. The 25 bushels of wheat also take from the soil, in the grain, 1.5 pounds of *magnesia*, and in the straw 1 pound.

Prac. Far. Why, I have heard it said that magnesia is injurious to crops, and that when farmers apply lime to their land, they should be careful to use that which does not contain magnesia! But go on; is there anything else in wheat? I can't stay much longer.

Science. In an acre of wheat yielding 25 bushels, there is in the grain 6 pounds of *Silica*, and in the straw 86 (eighty-six) pounds.

Prac. Far. Now I'm stumped! What on earth is *Silica?*

Science. The book says it is the substance of *flint* or pure *sand*.

Prac. Far. What! the substance of flint or sand in wheat! Pray, Mr. Science, how does it get there?

Science. You know that sand can be melted, as is done in the manufacture of glass, by the application of heat with soda and other chemical substances; and this book tells us that it becomes soluble in water by the aid of the potash and soda before mentioned; and when thus dissolved, it is taken up by the roots of plants. But I have not yet got through with the component elements of wheat.

One acre of wheat yielding 25 bushels, also contains in the grain, ¾ pound of *sulphuric acid*, and in the straw 1 pound.

Prac. Far. Why, that is oil of vitriol, is'nt it?

Science. There is also taken from the soil, by 25 bushels of wheat in the grain, 0.6 of a pound of *phosphoric acid*, and in the straw 5 pounds: also in the grain, 0.15 of a pound of *chlorine*, and in the straw 0.9 of a pound. This is all, and you must remember these are inorganic substances, such as do not grow like vegetables, and therefore they must be extracted from the soil. The total amount of these inorganic substances taken from one acre of ground yielding 25 bushels of wheat, and including the straw, as it is usually cut by the cradle, is 120 pounds. Three-fourths of this is silica, which is rendered soluble by the alkalies, potash, soda and lime, thus showing the great importance of these substances in soils producing wheat.

Prac. Far. Well, I declare I did not know that wheat had so many things in it. I always *thought* that wheat grew out of the ground, and got its food from the vegetable manure that was contained in it, or was put there by the farmer.

Science. Well, friend, you knew before by sad experience, that vegetable manure *alone*, would not raise wheat; for you say that when you put manure on your land, your wheat all went to straw, which was so weak that it fell down flat on the ground, and had no berry in the heads; and when you sowed your wheat without manure, it was struck with the rust, and the grain shrivelled so that you got no more than half a crop. Now you see that this book has told you some things that you did not know before, and which perhaps you never would have found out by your own efforts, without calling in the aid of science.

Prac. Far. Well, if the wheat plant contains all these substances, and they are all extracted from the soil, how are we *practical farmers* to know when they are not present in the soil? and above all, how are we obtain all this potash, and soda, and lime, and flint, and sulphuric acid, and phosphoric acid?

Science. The failure of your wheat crop for a series of years is pretty good evidence that *some* of these substances are wanting in the soil, but it will not decide which. The only way to determine which one of the foregoing substances may be wanting, is to call in the aid of *science*, and have a correct analysis of the soil made. But, nevertheless, by the nature of the disease that affects the crops, we may be able to judge more correctly of the substance that may be wanting. When the straw is weak and not able to stand erect, it may be certain that the alkalies are wanting to produce the silicates which are deposited in the stem, to give it strength and firmness. This book, however, will tell what substances you must procure and apply to the land, which will supply the ingredients contained in the wheat plant.

Prac. Far. I should like to hear something more about these matters.

Science. This book gives an account of the component ingredients of wood ashes. It says that "ashes always consists of a mixture in variable proportions of carbonates, silicates, sulphates and phosphorates of *potash*, *soda*, *lime* and *magnesia*, with certain other substances present in smaller quantity, yet more or less necessary, it may be presumed, to vegetable growth." "But they contain also, a greater or less quantity of imperfectly burned carbonaceous matter," or charcoal. Here you will perceive that you have nearly all the substances at once, of which the wheat plant consists. It would seem then, that if ashes be mixed with the soil it will supply the greater part of the substance of wheat. Did you ever think of this before?

Prac. Far. I have heard it casually remarked that ashes were useful, sowed upon wheat; but I never gave the subject much reflection, and therefore it did not strike me very forcibly. But does your book tell anything about the action of lime? I feel somewhat anxious to know this, for I have limestone on my farm and I have a mind to try it.

Science. Yes, this book gives an interesting account of the beneficial action of lime upon soils, and sums up its conclusions as follows:

"Lime improves the quality of almost every cultivated crop."

"It supplies a kind of inorganic food, which appears to be necessary to the healthy growth of all cultivated plants.

"It neutralizes acid substances which are naturally found in the soil, and decomposes or renders harmless other noxious compounds, which are not unfrequently within the reach of plants.

"It changes the inert vegetable matter in the soil, so as gradually to render it useful to vegetation."

Prac. Far. It appears then, that lime is useful to vegetation in *other* respects than in furnishing this ingredient to the plant.

Science. There are a *variety* of other substances described in this book which are usefully applied to vegetation, both in ameliorating the soil and in furnishing specific substances to the growing crops. But it will detain you too long, I am afraid, to read all of these to you now.

Prac. Far. That must be a good book for farmers, I should think. What is the price of it? Where did you get it? I will certainly have to get me one.

Science. It may be had at most of the book stores in the State for a few shillings, and the title of it is, Lectures on Agricultural Chemistry and Geology, by James F. W. Johnston.

Mt. Talbot, Champ. Co., 1845. D. L.

*NOTE.—The weights here given are in pounds and decimal fractions, thus: 3.3 is three pounds and three-tenths of a pound, and 0 15 is fifteen-hundredths of a pound It may also be remarked, that the language here used is not taken from the book alluded to by the writer; only the substance is obtained therefrom.

Symphytum or Comfrey.

From the Genesee Farmer.

In searching for aids in a new self-supporting system of general and liberal education, especially in the physical and dietetic departments, I was led, some ten years ago, to commence a series of experiments upon this vegetable; the interesting results of which I began, in September, 1842, to communicate publicly in my native eastern region. This, for the public benefit, I wish still to do, as opportunity shall be offered.

I have found this article truly of rare value; the *herb* made into hay for cattle, and the *root* dried and ground to flour for man.

It is a native of this and many other countries—found both in a wild state, and also cultivated in many gardens for its healthful qualities. It is perennial, very hardy, the crop sure, the growth luxuriant, the produce abundant, while the labor it requires is very small. In 1841, I obtained of two years' growth of roots, on soil of moderately good tilth, after the caps of the roots were taken off to replant, when thoroughly dried and ground, at the rate of 24,200 pounds of flour to the acre. In 1842, I obtained on the same soil, from the herb of the second years' growth, at two cuttings, at the rate of 11,616 pounds of well-made good hay to the acre. It requires no other tilling or attention than digging the crop of roots in April, once in two or three years, and planting as you dig, about 7 or 8 inches apart both ways; and cutting and haying the herbs, once the first year, and twice a year afterwards.

When ground in a coffee or corn mill, the root flour may then be used like other articles of food, according to the requisitions of health, convenience or fancy, in various breads, gruels, puddings, griddles, soups, pastry and custards, and in such proportions as may be found agreeable. It is (like arrowroot, sage and oatmeal,) very mucilaginous, nutritious, and easy of digestion. It operates well for the lungs. It has restored a lost voice, and is one of the best remedies for habitual coughs and incipient consumptions. It nourishes the feeble and suits well a dyspeptic stomach, when no other food can be kept down; and it sets all right in the bowels. I think it one of the best articles for sustenance and health ever made for man, and that on almost every account. But let others cultivate and try it for themselves, and it will probably, with them as with me, be constantly growing in their estimation.

EZEKIEL RICH.

From the South Carolinian.

Talking vs. Doing--Remarks on the Past--Hints for the Future.

No argument like matter of fact is,
And we are best of all men led to
Men's principles, by what they do.—*Hudibras.*

Assem Hacchem, in his celebrated letters to Mustapha Rub-a-dub Keli-Khan, was right when he said we were a nation of talkers—a body politic of slang-whangers. And we of the South, good men and true as we may be, and right sore upon this subject as we are, must confess the fact, that we are a wondrous people, for raising a tempest in a tea-pot. A few years ago when cotton fell from $18 to $8, what a sensation was produced by it. The country was ruined, all cried aloud. Nobody could stand it—to grow cotton at 8 cents was ruinous to the planters. It was sheer nonsense to talk of competing with the West on our worn out lands. Emigration was all the rage, and thousands moved westward and buried their fortunes. Others staid at home and talked of Reform, Economy and Patriotism.

Agricultural Societies sprang up everywhere. Newspapers teemed with Agricultural essays. Speeches were made—committees appointed, and premiums offered; and now it was as plain as the nose on a man's face, that cotton could not be grown on our exhausted lands at 8 cents. We must reform—we must improve our soil—we must sow grains and grasses, and raise our own stock. This immense drain of our capital by the West must be stopped. And, like Aladdin's lamp, all these things were to be done like magic. It was to be done in a moment. We could never wait for each reform to be effected gradually—it must be "Presto—change," or not at all.

Short horns and Ayrshires, Berkshires, Woburns and Graziers were in great demand—you could hear of nothing else. And our Yankee and Western brethren, who are always on the watch, to pick up suckers—threw out their bait, and we were "cotcht." The Northern papers were filled with the wonderful properties of different breeds of animals, the Southern papers echoed the story—the people ran mad—bit, and were bitten. It would be a sore subject now to many of us to speak of the prices which we paid in those days for the "improved breeds."

It seems inevitable that we are to be taxed for our experience as well as for our wares and merchandize. It is our own fault.

Then we began to make manure lots upon the poorest, bleakest places we could find, wherein our cattle, poor things, were to be penned up during winter, resting upon piles of wet litter without a shelter to shut out wind or rain. Manure, such as it was, was made, carted out, and the work seemed fairly begun, so far as talk and the newspapers could go, the problem was solved—we were made a people, every body was surprised, that everybody did'nt see it long ago. A few years have passed away, and it is all over. You hear people saying now, manure won't do. We can't make enough of it, and it won't give the results of the newspaper writers. We must have fresh land. Durhams don't suit our country—they are not adapted to our system of grazing—bless me, what is? That Berkshires and Woburns and Graziers are all humbugs! That if every man makes corn, nobody can sell it, and when one does sell it, the money comes in "dribbles" and does a man no good. He spends it as fast as he gets it—pray, whose fault is that?

Thus they talk, and everybody has gone back to cotton at 4 and 5 cents per pound, and puts in just as much as he can tend, making quantity answer his purpose. The receipts in our markets go plainly to show that there is no falling off in the quantity produced on our exhausted lands, and but for the extremely unfavorable spring, we have no doubt as much would have been put in on an average as ever. It is a strange thing, really, that at a time when the country was comparatively out of debt, our staple at a low price, and our lands exhausted, that the planters should steadily refuse to carry out a reform, which would work out incalculable advantages to the country.

The truth of the matter is, we all want to be big folks. We want to roll our cotton down to market and get the money all in one big lump. We have got into that way of doing things and we can't bear the idea of this piddling business in dollars and cents. We know nothing of the old adage, "a brisk penny is better that a slow shilling." We are in too great a hurry to wait for the end. In truth, we are always in too great a hurry—it must come at once or never. We are the creatures of impulse, which may do very well for sentiment, but belongs not to farming, stock raising and manure heaps—everything therein must go its regular course.

We have reformed but indifferently—we must reform altogether. No half way point is there in this matter—there must be a regular system to be adopted and worked out to the end without any shrinking from the purpose.

Manure lots should not be built anywhere on the side of a hill, or in the depth of a valley. They should be constructed as if they were to be there for one's posterity. It is the fatal error with us, that we do everything in a hurry, and as it were "*pro tempore.*" And when manure is applied to the earth it should be in such a manner as to tell its own story. It is far better to manure a small field well, than a large one badly.

Cattle and hogs of improved breeds should not be introduced before we are ready for them. Recollect that we have none of the conveniences for raising such things; treatment that might answer very well for our brindled cattle and razor backed hogs would soon kill an "improved" animal. We must not expect to produce like from like, unless it be by like treatment, that's certain.

We must begin by degrees and not jump in *medias res* at the first bounce—nonsense all this.

With the same pen of shucks we expect to keep up the same old stock, and the improved breed into the bargain. Better had it been for us if we had kept our old stock and improved by judicious selection and feeding until we learned from experience the benefits of such a system—then we would be prepared to introduce your Durhams, Devons, et ceteras. We do verily believe that it would be an absolute saving to most of our planters, and a manifest improvement upon their stock, if they would knock in the head and skin one-half their live stock at the beginning of every winter.

To succeed, we must be fixed for such things. Meadows cannot be made in a day, nor will old sedge fields answer all the purposes of grazing. Old habits like ours cannot be changed in a moment—all these things must be the work of time, labor, perseverance, energy and economy. It will be a long time before you can teach a cotton growing people such a doctrine--yea, we fear it will never be done, till every stick of timber is destroyed, and every corner filled with an inhabitant. NONDESCRIPT.

The Grape and Wine Making.

From the Alabama Planter.

We had placed in our hands a private letter, not intended for the use we are permitted to make of it, which contains some valuable hints on the cultivation of the native grape and wine making. The writer has for many years taken a lively interest in the agricultural improvements of our State, and bestowed no little pains by close and patient experiments, in developing her resources. He has done more perhaps than any other man in ascertaining what products will succeed and amply reward the cultivator for his labor. Therefore, we have entire confidence in what he says in regard to the native grape. If, however, other evidence were wanting of his knowledge and skill--of the superior quality of his grapes, and his ability to extract from them a nectar that the gods might sip with delight, we have it in a sample of wine of his own vintage.

Whether or not this worthy gentleman's admirable system of farming and domestic economy is ever adopted generally by our people, he will enjoy the satisfaction of having done all in his power, both by precept and example, in pointing out the true road to prosperity and happiness.

Ten or twelve years ago the same gentleman published through the Alabama State Intelligencer, conducted at Tuscaloosa by the writer of this article, a series of interesting papers, designed to impress upon planters the policy of a more varied system of culture. As a proof of their merit, they were very generally copied by the Southern press, although put forth at a time when cotton was more exclusively cultivated than at the present. Recently he has written for the Register of this city a number of communications of a highly practical character; and, devoted as that paper is, mainly to commercial affairs, they have been promptly published and received with approbation by a large number of its readers. This certainly may be taken as gratifying evidence that already a deep interest is awakened on the subject of Agriculture. We trust the future numbers of the Alabama Planter will be graced by contributions from the same source.

But to the letter:

"I make annually for my own use and to scatter amongst friends, from 75 to 100 gallons of wine. I prefer it for a summer drink, using no spirits. The red wine was made from our native uncultivated grape, which abounds through this section of country, some of the finest varieties of which I am cultivating, previously having determined their qualities as regards producing a good wine.

There is an astonishing variety in the product of our native grape, all of which are cultivated with great ease, and exhibit on cultivating an improvement hardly credible.

Among other properties possessed by our native grape, the quantity of vinous matter they possess is most remarkable. A bushel of bunches as pulled from the vine will give three gallons of the wine I sent you; and after undergoing a second operation, about one gallon more of a lighter but most agreeable wine. It would take a third pressure to produce the mea-

ger drink with which they in part feed the peasantry in France, &c., who tend the vintage. I anticipate most agreeable results from the cultivation of our native fruits, based on the trials I have already made.

The white wine I sent you, is from an American grape acclimated to this section of the country many years ago. It is a redish colored grape, resembling the Catawba, exquisite for the table, a great bearer and hardy.

As regards the cultivation of the grape and wine making, I have effected one most desirable object, viz: doing away altogether with that great expense of which so much has been wrote and said. The ground in which my vines stand and bear, produce me annually two other crops; say a crop of Irish potatoes, and after they are matured and taken from the ground, another crop, the same year, of a variety of the red sweet potatoe, a most valuable variety for stock and most productive. My mode of supporting the vine is simple, efficient and economical. The manure given to the Irish potatoe crop is ample for the vines, and applied in the best possible way. The superiority of the grapes I produce, as regards quantity and quality, has been often loudly remarked by our own citizens and foreigners.

I have a splendid collection of the apple, all acclimated. The cider apple is perhaps the most beautiful tree of the kind you have seen, a most free grower and prolific, bearing annual full crops. It is the best apple to hang on the tree and the freest from rot I have ever seen. It cannot be surpassed in the Union. It is a native of Alabama, produced from repeated planting of seed and grafting and regrafting for the last twenty-five years.

A vineyard at maturity, say the fourth year, would be good for from 500 to 750 gallons—the seventh for 1,000 gallons—the Scuppernong much more to the acre.

My mode of planting and cultivating the grape, half the quantity per acre and the annual crop mentioned, please me better. Ground with us is plenty, and potatoes are as essential to our comfort as wine. In fact, in every species of cultivation I am every day more convinced, that mixed cropping is the true mode of employing soil and labor. In this way the expense and labor is singularly decreased in proportion to the product.

By giving the vines room I insure heavy crops of grapes and rich fruit. I tend, prune, etc., with satisfaction; the first with the plow and a little with the hoe while making the potatoe crops. The room enables me to gather the fruit with ease and readily.

I employ the trellis in cultivating the grape. In all respects it is the best. Our native and such other grapes as I cultivate prefer it. This appendage to the vineyard costs me about $5 annually, per acre, including pruning. I cut down sassafras or cedar trees, say 9 to 10 inches diameter, into posts 8 feet, point the but end, put the small end in the ground, 10 feet distance, nail on the sides lathes about two inches square, just as split from the cypress log, and my trellis is done. My tying, the best I have ever found, is the bear grass, found readily in the woods profusely scattered in spots—shrunk over the fire, when green, it becomes a sott, pliable tying. Thus you see, I am all economy, and no part of the "Indian's gun," cost more than it eame to."

NUTRITIVE QUALITIES OF PEAS.—Peas contain a larger quantity of nutritive substance than almost any other vegetable. Liebig says they abound in vegetable caseine, the third constituent of the vegetable food of animals, which is, in fact, vegetable cheese. Caseine is chiefly found in peas, beans, lentils and similar leguminous seeds. The following comparison of the ingredients of vegetable (caseine) and animal (milk) cheese, is taken from Liebig's tables:

100 *parts Vegetable Cheese.*		100 *parts Animal Cheese.*	
Carbon	54.133	Carbon	54.825
Hydrogen	7.156	Hydrogen	7.153
Nitrogen	15.672	Nitrogen	15.628
Oxygen, &c.	23.034	Oxygen, &c.	22.394

On the Cultivation of the Raspberry.

From the Magazine of Horticulture.

In our last number, we gave an article on the cultivation of the currant. It was the first of a series of papers we intend to offer upon the cultivation of all the fruits of the garden, which have not been previously written upon by ourselves. We now proceed to treat upon the growth of the raspberry.

The raspberry, like the strawberry and currant, and other small fruits, the gooseberry excepted, has been greatly neglected in its cultivation. Though common in every garden, and everywhere esteemed, next to the strawberry, for its rich and handsome fruit, yet few individuals have attempted improved methods of growth, by which the size, beauty, excellence and productiveness of the berries may be increased to a much greater degree than they are generally seen in our gardens.

The raspberry is as susceptible of improvement as the strawberry: yet, while in the latter we have the beautiful Keen's seedling and our own variety, contrasting with such marked superiority over the small and inferior berries of the older sorts, the same varieties of the raspberry are now cultivated that were common twenty or thirty years ago, and they are still deemed the most desirable sorts. The same attention bestowed on this fruit, that has been devoted to the gooseberry, would undoubtedly have resulted in the production of varieties much superior to those at present grown.

The raspberry, like the strawberry, is a native of low and partially shady situations, growing in boggy or soft black soils, which allow its roots to strike deep, and throw up a free growth of its vigorous suckers. It is only in such situations, in their wild state, that the plants are found productive; on light and thin soils, and in high and exposed situations, the growth of the suckers is limited, and the fruit scarcely ever attains any size. Nature thus teaches the proper mode which the cultivator should adopt in the growth of the plants; and it should be his object to follow her, rather than to divert and thwart her in the course she has pointed out for us to pursue.

But how different is the cultivation of the raspberry from what we should infer from nature to be most conducive to its healthy growth. The plants are frequently set out in light and poor soils, crowded together, left untrimmed, choked up with a profuse growth of weak stems, and what little fruit they produce nearly dried up, from the arid situation in which they are placed. On the contrary, in cool, deep, and moist soils, in a sheltered and partially shaded place, the plants throw up suckers to the height of six or eight feet, and produce a profusion of large, handsome, and well flavored berries. So well assured are the most eminent English cultivators of the raspberry, of its love of a cool and moist soil, that some writers have strenuously recommended the use of bog earth and rotten leaves, in the place of the richest loam. We are well assured that the many complaints which are made of the meagre produce of many raspberry plantations, may be attributed wholly to the light and droughty soils in which they are often planted.

We would not here omit to mention the production of seedlings for the purpose of securing new sorts. By hybridization of the kinds, and by selecting the finest and largest fruit, from which to save the seeds, we are certain new and superior varieties can be raised.

To induce cultivators to give more attention to the raspberry, is the object of this article; and to render our information the more useful, we shall treat of its growth under the following heads: Situation—Soil—Procuring Plants—Planting Out—Winter Treatment—Summer Treatment—Autumnal Dressings—Pruning—General Remarks—and Descriptions of the different varieties.

Situation.—A cool aspect is of material consequence; and to secure this, the north side of a fence or trellis, which will form a screen from the sun, is the most favorable: on the north side of a shubbery, or row of fruit trees, is also a suitable place. If neither of these situations are to be had, an open spot in the garden may be chosen, always being careful to avoid the south or east side of a fence. A temporary shade may be effected in the open garden, by planting a row of running beans on the south side. Having selected a proper place, proceed to prepare the soil.

Soil.—A good soil is the most important requisite. Having marked out the size of the bed, if the earth is not naturally very rich and deep, preparations should be made to trench it. First cover the surface with three or four inches of bog earth if to be procured, or, in its place, leaf soil, and if these are not conveniently to be had, good old rotten hot-bed manure, which has laid at least six or eight months: that from hot-beds made in April will do for use in the following October, and if a portion of the bed was leaves, it is so much the more to be preferred. Having spread the manure upon the surface, it should then be trenched in two spades deep, or about eighteen inches, placing the manure at the bottom of the trench. Level the surface, and spade in an inch or two more of the same kind of manure, and after allowing a week for the bed to settle, it will be ready for planting.

Procuring Plants.—The success of planting out depends considerably upon a judicious selection of plants. Suckers of all sizes are generally thrown up, and many cultivators would naturally select the largest: such, however, are not the best; those of medium size, neither too large nor too small, have the finest roots, and spread more rapidly than the others. In selecting, reference should be had to the roots rather than the tops.

Planting out.—Having prepared the beds, and secured a sufficient number of plants, preparations may be made for setting out. A spade, a rake, and a garden hoe will be the proper implements to accomplish this. The bed being marked out, stretch the line across the bed, from east to west, at the distance of two feet from the walk: commence on either side of the line at one end, by taking out the earth the width and depth of the spade; place in the plant against the line, and throw the soil out of the second hole to fill up the first: in this way proceed until the whole bed is planted, treading the soil lightly around each plant; with the rake smooth and level the whole, and the work is finished. The rows should be three feet apart, and the plant three feet apart in the rows.

Winter Treatment.—On the approach of cold weather it will be necessary to protect the plants for the winter. The best method of doing this is simply to bend the branches down to the ground, and cover them with four or five inches of the soil. Some cultivators use leaves, and others coarse manure, but we believe nothing answers better than the common soil in which they grow.*

Summer Treatment.—As soon as danger of cold weather is over, which is generally the first of April, the plants should be uncovered, and a stake placed to each, to which the stems should be securely tied: the first summer very little must be expected from the plantation, and only a few suckers will be thrown up from each plant; but by the second year they will be more numerous, and produce considerable fruit. As soon as the plants are tied up, proceed to level the ground, and give it a neat finish with the rake: the only after culture is to keep down the weeds, and the surface loose, by occasional hoeings.

Autumnal Dressings.—Enriching the bed at time of planting is not sufficient to keep the plants in good condition. The beds should have a dressing of two or three inches of compost every autumn. This should be laid on in October and lightly forked in, bearing in mind that a mixture of bog earth, or leaf soil and manure, is better for the plants than all manure. This will encourage the growth of the roots, and in

* Not necessary in the Southern States—ED. CULT.

the spring, the suckers which are thrown up to form the bearing plants of the next season, will be much stronger.

Pruning.—The raspberry can hardly be said to need pruning in the common acceptation of that term. All that is required is to shorten the most vigorous bearing stems, and to cut away the old wood after it has produced its fruit. The second summer after planting, the plants will throw up a quantity of suckers; if numerous and small, four or five of the best should be left their entire length; if large and strong, they should be shortened to four or five feet, and the superfluous ones rooted up, unless wanted to form new plantations.

General Remarks.—As the raspberry is a rapid grower, after it once takes hold of the soil, quantities of suckers will spring up, which, in the course of four or five years, will weaken the plants. On this account new plantations should be made every fifth or sixth year, and the soil trenched and renewed by the application of the compost already mentioned.

The raspberry is rarely attacked by insects. We are not aware that we have ever been troubled with any during our cultivation of this fruit, for upwards of fifteen years. On this account, it requires very little care at the hands of the cultivator. As a market fruit it is particularly worthy of attention, requiring less care than the strawberry, easier picked, and the finer sorts commanding a good price.

The following is a list of the best kinds now cultivated. A few of them are new, and, as yet, not very extensively known. The kinds we would recommend are the white and red Antwerp, and the Franconia; for larger gardens, all the others may be added, which will afford a great variety, and a succession of fruit. The names, with the exception of the three last, are according to the London Horticultural Society's *Catalogue.*

Description of the Different Varieties.

Red Antwerp.—Of fine size, excellent flavor, and productive; one of the best.

Yellow Antwerp.—*Syn.* White Antwerp. Similar to the last, except in the color of the berries; a delicious fruit, but does not bear carriage well.

Barnet.—*Syn.* Cornwall's Prolific. A fine, large, red fruit, productive and excellent, but does not bear carriage well.

Common Red—*Syn.* Old red. The old kind of the garden. An indifferent bearer, and of inferior quality.

Double Bearing.—*Syn.* Perpetual bearing. Said to be a good and productive kind, having the merit of producing one crop in July, and another in September.

Franconia.—*Syn.* Seedling Grape. One of the most productive and finest kinds cultivated around Boston. Fruit red, large, and handsome. The origin of this sort is unknown. It was originally received from Vilmorin, of Paris, by S. G. Perkins, Esq., of Brookline.

New Red Antwerp.—It promises to be, so far as we have tried it, a very fine variety.

Cretan Red.—A fine variety, the fruit large and handsome, rather more tart than the Antwerp, and continues in bearing a long time, which renders it highly valuable.

Besides the above eight sorts, the *new Turkish Turban, Victoria, Brentford, Spring Grove*, and the *Ohio Ever-bearing*, are recommended as very fine kinds. To those who have room, we would advise a trial of them.

[Since the above was written, a new variety of the Raspberry called the *Fastolff* has been introduced. It is highly extolled in England, but has not been tested in this country to any extent, but roots are in much demand this spring.]

WASH FOR THE HAIR.—The American Farmer says a ½oz. oil of burgamot put in a quart of uncolored N. E. rum, well shaken together in a glass vessel, and applied twice a day, is one of the best washes ever applied to the human hair, and prevents its falling out.

Cheeseology.

During the hot part of the summer the farmer's wife will use the milk of her cows in the manufacture of cheese. Now, although anybody can put a quantity of rennet into milk and change it to curd, and then, after separating this curd from the whey, give it a good squeezing, every one cannot do this in the right way to form first rate cheese. A friend who has charge of a small dairy, asked us the other day to publish some of the "ways and means" of making good cheese. We therefore, out of pure good will to the ladies, re-publish our article on Cheshire cheese, and also throw the following hints in to boot, which we obtained from an old cheese maker in New York, and which have been published several times in different forms and places.

He observes that the first step is to prepare the rennet properly, which is done by steeping it in water or sweet whey, which is preferable, and adding salt enough to keep it sweet. The quantity of rennet used in a given quantity of milk, must be regulated by its strength. Some rennets are better than others, and therefore the strength of the liquor which a given quantity will make is uncertain.

Put in enough to perfectly curdle the milk. If you should put in too much the cheese will puff up full of holes and have an unpleasant taste.

In hot weather, when milk will be likely to sour in the evening, it should be cooled down to from 45 to 55° of the common thermometer (Farenheit's) which may be done by setting the pans in a cold place, or setting them in cold water. Or, if you have milk enough for large tubs, put in coolers or tin vessels full of cold water, so as to bring down the temperature of the milk. In the morning many skim off the cream which has risen, and put it by itself in a pan. You then prepare to set the milk, as it is called. Take some of the milk and heat it to blood heat, i. e. as warm as milk is when it comes from the cow, and pour the cream into it. There should be enough of this milk to liquify the cream. Then raise the whole of your last night's milk, together with that of the morning's milk as it comes from the cow, and pour all together, that which has the cream with the rest.

Then add the rennet and let it curdle, which it will do in about an hour. It may be considered to be all curdled when it will admit of a slight pressure without breaking.

While this is going on, some cream may rise to the top. Be careful and not let this escape with the whey, but skim it to one side of the tub, and put some curd on to it with a skimmer. And you must be very careful in breaking up, not to let too much, or, indeed, any of the cream or buttery particles become mixed and escape with the whey. Spread a coarse cloth or strainer over the whole, and let the whey rise up through it, and dip off as much as you can easily. Then remove the cloth and break the curd again as fine as you can with a skimmer, and dip off the whey again carefully.

Some of the first whey should be heated immediately after it is dipped off, and by the time the second whey is dipped off, the heated whey should be ready to scald the curd. Our informant says that it should be heated to about 130°, a little more than half as hot as boiling water, and that two pailsful were enough to scald the curd of forty pailsful of milk.

As soon as you have dipped off the whey the second time, break up the curd again, and pour on the hot whey and thoroughly mix it, and break the curd up with the hand as fine as you can.

Then cool it by pouring on cold whey. Then move it into a cheese basket, over which a cloth is spread, in which all the whey is worked out by squeezing the curd as clean as possible.

Then put the curd into the cheese tub and salt it. Some add a teacupful to every 15 lbs. of curd, but a better way is to salt it to suit the taste. The salt should be thoroughly mixed, for if this is not done some parts of the cheese will puff up and have a different taste.

It is now ready for pressing, which should be faithfully done. Although there may be danger of pressing too much, there is more danger of not pressing enough; and cheese not sufficiently pressed, will not keep well.—*Maine Farmer.*

Economy.

From the Southern Planter.

Perhaps the most marked trait in the character of the Southern farmer is the want of economy. Many reasons have been assigned for the depressed state of agriculture in the South. That our country enjoys the most unrivalled advantages for the prosecution of agricultural pursuits, is undenied and undeniable: that the improvements in this art have not kept even pace with other departments of science, is universally admitted. The inquiring mind, which seeks for reasons for every fact, has been engaged in the explanation of this phenomenon. Some have declared that the light of science was wanting to the pursuit of agriculture; some have attributed the stationary character of this pursuit to the existence of a slave population, &c.

That the science of agriculture is in its nature one of the most complex and intricate, a little consideration must satisfy the most careless observer; and the fact that a *season* is required to test an experiment, proves, that experience, which is the foundation of true knowledge, is more difficult of attainment in this than in any other art. But this is true of agriculture everywhere, and only accounts for the retarded progress of the art when considered in relation to the world generally. It has been asserted, however, that in the Southern part of the United States, the portion of the whole globe perhaps best adapted to the pursuit of agriculture, improvement languishes most. Whilst we are not prepared to admit this charge to its fullest extent, we will confess that agricultural improvements encounter peculiar difficulties in their progress through the Southern States; not, as some imagine, for want of knowledge of the scientific discoveries in agriculture, for they, we believe, in truth, are very few, and are as well known to the enlightened farmers of the South as to any portion of the Union. But the fact is, that amongst the highly favored, wealthy farmers of the South, a state of financial embarrassment prevails, that offers an insuperable bar to agricultural improvement. It is not uncommon to find a Southern farmer with real estate and negroes worth fifty thousand dollars, sadly embarrassed with a debt of twenty thousand. Our Northern friends will wonder how a man with fifty thousand dollars' worth of property can be seriously embarrassed with a debt of twenty thousand, but a Southern man will readily understand the feelings and sentiments which make it so distasteful to part with that peculiar kind of property in which a large portion of his funds is vested. But unless he sell his slaves, the farmer cannot part with an acre of ground, which is, in his opinion, hardly sufficient to keep them employed. Thus it is, that the debt is not only retained, but perhaps from the same cause from which it originated, it is increased, and to provide for the interest alone, absorbs all the funds and much of the time of the improvident farmer. It were bootless to look to the origin of this state of things; it could perhaps be traced to the fact of expensive habits derived from a wealthy ancestry, whilst the enormous profits that justified them in former years, have altogether ceased in later times; for whilst there is no difficulty in expanding your expenses in prosperity, the contraction in adversity is not quite so easy. Be that as it may, the fact of a very general pecuniary embarrassment amongst even the wealthy portion of the agricultural community in the South, is not to be denied; and this circumstance alone, when fully considered, will be found sufficient to account for the retarded state of agricultural improvement in the South. Money is the great lever with which the world is both raised and lowered. Suggest to a farmer a system of cultivation by which his exhausted fields may be rested and restored; he is fully aware of it, but he tells you that the corn from that field is devo-

ted to the liquidation of a debt already incurred; prove to him that if he is deprived of this resource for a year or two, it will only be to double the product in after time; he knows it; but even with the yield of that field, he fears that his income for the year will fall short of his expenses. He hopes that it will be better after a while, but *this* year, he must "make every thing tell." Show him a valuable labor-saving machine, an investment in which would be equivalent to an interest of fifty per cent., his answer is, "My dear sir, I am a borrower, not an invester of money;" and so he is, poor fellow. It is not the want of scientific knowledge that keeps that man's fields poor, and induces the most skinning system of cultivation, but it is the want of pecuniary means.

What is the remedy for this state of things? We answer emphatically, *retrenchment and economy*. Begin with yourself; curtail your individual expenses, go through every member of your household, cut down and pare off everywhere; teach your children that the conveniences and elegancies purchased of the milliner and the mercer, may be substituted, in a great measure, by their own handicraft. Your own part is nothing, but to deprive those you love of that to which they have been accustomed, is, we know, a bitter pill; but it must be taken. In the great fall of agricultural products, there is no help for it.

Do not tell us that you already practise economy to its fullest extent. My dear sir, you don't begin to know the meaning of the word. What is your income? About $1500—well, go to the North and see how a farmer with an income of $2000 lives, compare your expenditures with his, and then see if you know anything about economy. And whilst you are there, observe the difference between his case and yours—he probably has at the end of the year eight hundred or a thousand dollars to devote to the improvement of his land, which improvement probably secures him a surplus of twelve or fifteen hundred dollars at the end of the next year, and so he goes on, getting richer and richer, whilst you are getting poorer and poorer. Suppose your situations to be nearly the same in 1845, work this thing out, and see where you will both be in 1855.

There is one point upon which we will take the liberty of giving you the glentlest hint in the world. Be not afraid in this proposed system of reform of any opposition from your wife. Come out like a man and explain to her the necessity for it; women are always more frugal and self-denying than men; we'll answer for *her*.

It is astonishing how not only the *price* but the *real value* of land, is affected by the economical habits of a neighborhood. We were sensibly struck with this fact in a conversation last summer with an intelligent gentleman from Rockingham. We were both at the time in the county of Albemarle, and something was said about the high price for which land was sold in that county. The Rockingham gentleman remarked, that similar land in his own county, not at all more productive, farther from market, would sell for one-third more money. He was then asked, why he did not sell in Rockingham and purchase in Albemarle. He replied, because he found, upon a fair calculation, that the land was cheaper in Rockingham than in Albemarle; that is, that owing to the different habits and customs of the people, he could lay up more money from an investment in the one than in the other. This is sound reasoning, and it is the reasoning upon which men are induced to give a hundred dollars an acre for lands in New York or Pennsylvania, whilst lands equally productive can be purchased in Virginia for half the money.

YEAST.—To show the nature of yeast, philosophically considered, we give an extract from a lecture delivered at Bristol, England:

The first point brought by Mr. Carpenter under the notice of his auditors, was the *vegetable nature* of yeast. He states that the phenomena of fermentation had long been a source of perplexity to chemists; a change being produced by the action of this substance in the fluid with which it is mixed whilst it does not itself enter into any new combination, but on the other hand is greatly increased in amount. This mystery is now explained. On looking at yeast with a good microscope, the mass is found to consist of a number of minute disconnected vesicles, which greatly resemble those of the red snow (Protococcus nivalis.) These, like seeds, retain their vitality for almost any length of time; and their power of growing, when placed in proper circumstances, not being destroyed by exposure to such extremes of temperature as 76° and 112°, or being dried in a cake. When these are placed in a saccharine solution, they commence vegetating actively, provided the temperature be sufficiently high. If a fluid thus excited to fermentation be examined at short intervals, it is observed that each vesicle puts forth one or more little prolongations or buds, which in time become new vesicles like their parents; these again perform the same process, so that within a few hours the single vesicles have developed themselves into groups of four, five, or six. By the time that five or six vesicles are formed in each group, the fermentation is sufficiently advanced for the purposes of the manufacturer, and he then takes measures to check it. The vegetation of yeast is then suspended, and the groups of vesicles separate into individuals, the mass of which constitutes the yeast thus largely increased in amount. The vesicles multiply also by a process analogous to the formation of seed in the higher plants. Some of them are observed to burst, and to emit a number of minute granules, each of which developed itself into a new cell, as in the case of the red snow.

Very few farmers fully appreciate the advantages of the improved agricultural implements

The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 9...SEPTEMBER, 1845.

The Maine Farmer.

Our friend and co-laborer, Mr. Holmes, of the *Maine Farmer*, copies two articles from our paper of July, and speaks of them and of the South as in the articles hereunto annexed. We copy his remarks, because we are pleased to have our efforts to serve the South commended in a quarter where we might suppose the prevailing interest to be that we should continue to indulge ourselves in the old folly of depending on others for the thousand and one things Yankee thrift and ingenuity have contrived to sell to us in times past: for instance, that we should continue to get Thomaston lime for building, when there is in Georgia alone better limestone, and more of it, than in all New England put together. But a more especial purpose of copying the article of the Maine Farmer, is, that we may protest, as we now do, against the imputation of referring to the action of the Tariff alone by the words "pillage according to law." Not by any means did we intend to be so understood. Yet, even if we had so intended, we do not see how offence could be properly taken thereat, after a New England Senator had made the declaration, in the U. S. Senate, that the repeal of the Tariff would make New England a howling wilderness:—a pretty plain admission, we think, that New England does live by the pillage of somebody, either according to law or somehow else. But this, most unfortunately for the South, has been made a topic of party politics, and has, therefore, been steadily avoided by us in the conduct of the Cultivator. We have a higher aim—we take more extended views of the subject, and our purpose was to be understood as referring to the whole system of national finance, revenue and expenditure both, but chiefly the latter. To show how the public money is spent so as to impoverish the South and enrich other parts of the Union—to make Maine prosper, for instance, and Georgia retrograde in everything—must be very deeply interesting to the whole cotton planting interest, who suffer so severely by the operation of the system. But to do this in detail would take up too much room. We can but refer to a few particulars as specimens of the whole. Where are all the large and expensive establishments of the United States government—fortifications, armories and navy yards—all requiring, to keep them up, the disbursement annually of millions of money? Who ever heard of a public ship being paid off at Savannah or Charleston? Oh no!—the millions that go that way must be paid out in Boston, New York and Philadelphia. What became of the millions squandered in the Florida war? The government, we believe, took good care that its favorites in that business should be chiefly Northern men. Look at the custom-houses and compare the miserable buzzard roosts in Savannah and Charleston with the palaces in Boston, New York and Philadelphia, costing, each of them, millions of dollars. Why has the Post Office Department recently gone to New England and got printed fifteen tons of blanks to supply eight thousand post offices under the new law? Gov. Hill is our authority for this. Why does the Navy Department go to New England for granite for building a dock at the Navy Yard at Pensacola? Answer us that, friend Holmes. The Government some years ago issued Treasury notes, bearing interest, some at six per cent. and some at one mill per cent. Somebody in Augusta asked another if he knew the reason of this difference. O yes, was the reply, the six per cent. notes are for the North—the one mill per cent. for the South. Now we don't, by any means, assert this to be a true account of the matter; but that it furnishes a very apt illustration of the working of the system there can be no doubt. What say you, Mr. Holmes?

These instances have been thrown together just as they occurred to us, without any attempt at arrangement for effect. They are but items in a very long account that might be written out. They are, however, fair specimens of the whole. Is it at all surprising that the cotton growing interest of the South should, with the late prices of our staple, be rapidly sinking under the operation of such a system. When cotton could be sold for 15 cents per pound, the planter made money so fast and so easily that he either did not feel, or disregarded the load that was put upon him by his government. But now, with an impoverished soil, and a price for cotton that for some years past has hardly paid the expense of culture, he cannot bear up under it with patience,

And now let us ask the editor of the Maine Farmer, if he were to leave his frozen regions, come to the sunny South, and were in the habit of seeing all these things as we daily see them, and as they really are, whether in speaking of the working of such a system, and its disastrous effects upon the condition of the people among whom his lot was cast, he would not be most likely to use language, to which the term "petulant" would be altogether inappropriate, as being too mild.

From the Maine Farmer.

"Good Lecturing for Home Consumption.—The editor of the Southern Cultivator, Mr. James Camak, of Athens, Ga., occasionally gives his brethren of the "sunny South," some wholesome advice in his paper, occasionally mingled with a hit at us Northrons for meddling sometimes with *some* of their institutions, and for being as greedy of *golden pelf*, as they are improvident of it. He is right in trying to rouse up a different spirit in his section of country. With every advantage which nature could bestow, what hinders them from outstripping us in the race of industry and prosperity? Nothing but their own supineness, backed up by incorrect and futile notions of the *servility* of labor and the nobility of idleness. The following, quoted from the Cultivator, shows the amount of their productions, and yet, with all their profusion, they cannot exhibit that evidence of thrift, comfort and independence that the North can. Why? Not from "the pillage according to law," which he, rather unjustly, not to say petulantly, refers to—by which, if we understand him, he means the action of the tariff, but from the other cause which he mentions."

[Here follows our article from the July number of the Cultivator, beginning with "Products of Southern Industry."]

"Now we should rejoice, (continues Mr. Holmes,) to see the South rise up as one man and practice on the advice which he has so faithfully given them. We should rejoice to see them carrying their surplus produce to Europe, in their own ships, manned by their own sailors. We should rejoice to see them starting up manufactures throughout their territory, operated by their own citizens. Why may not the spindle and the shuttle be heard by the side of the cotton field? It would perhaps curtail the profits of the North somewhat, but it would be productive of a great and singular blessing. It would create a unity of feeling between us—it would strengthen the bonds of the Union, in a common interest—it would do away with many false and ridiculous notions in regard to the respectability, or rather *disrespectability* of labor—and it would destroy much *splendid misery* that the world little knows about, and carry comfort and strength into many a family, that are now, perhaps, dependent on their fellow-beings for support.

Here is another lecture which he reads them, under the title of "Southern Folly"—he might have added, "Northern Folly too," for it is hard telling which ought to be rewarded with the greatest fool's cap, the South or the North. Any community who will play the fool so emphatically as have the Southerners and Northerners, about two *old mares*, deserve to be reproved every day in the year."

[Then follows our article on 'Southern Folly.']

The Agricultural Press.

The increase of Agricultural papers, in the Southern States especially, is very gratifying.

Since our last notice we have received the first number of the *North Carolina Farmer*, a very neat and well filled monthly, published at Raleigh, at $1 per annum.

The *Alabama Planter*, published weekly at Mobile, by W. W. McGuire, at $5 per annum, the first number of which we have received, is an exceedingly interesting paper, and, if supported, according to its merit, by the planters of that wealthy State, it must have a very happy influence on their interests and character.

On the 1st of October next will be commenced the publication of the "*New Orleans Commercial Times*—devoted to Commerce, Agriculture, Literature and the Arts." The Agricultural department is to be conducted by our correspondent, Mr. Thomas Affleck. We need not say with how much ability the task will be performed. The public have evidence enough of that in the essays of Mr. A., heretofore published in the principal Agricultural papers of the United States.

The *American Farmer*, the oldest Agricultural paper in the Union, has been changed from a weekly at $3 per annum, to a monthly at $1. In its new form it shows a decided improvement in every respect. We wish its intelligent editor, Mr. Sands, all the success his spirit and enterprise entitle him to. Judging from the two numbers which we have received, the farmers of Maryland are fortunate in having among them so able an advocate of their interests.

The first number of "*The Farmer's Library*," by J. S. Skinner, has come to hand. So far as the publishers, Messrs. Greeley & McElrath, are concerned, the work is very creditable to them. It is gotten up in very handsome style. This number contains three plates, two of which, the portrait of S. Van Rensselaer, and the picture of Southdown Prize Weathers, are admirable productions of art. Then, as to the Editorial department, it is only necessary to say, that J. S. Skinner has charge of it, to satisfy every one, that though the subscription is $5 per annum, the work will be really worth many times that sum. The first part of the number before us, 48

pages, contains part of Petzholdt's Lectures to Farmers on Agricultural Chemistry. The second part, 64 pages, is made up of seventeen very interesting articles, all closely connected with the every day business of the tillers of the soil.

Agricultural Statistics.

The reports from the Patent Office on the Agriculture of the United States, have, for two or three years past, been by far the most interesting document emanating from the Government. Mr. Ellsworth will long be remembered for the industry and the ability with which this part of his duty was performed. It is the intention of Mr. Burke to continue these reports—giving them, it possible, increased interest and accuracy. He can do this only by the aid of members of Congress, and their constituents. Mr. Cobb is taking the right course to get in his district the information wanted. Let his constituents, now, do their part. See Mr. Burke's letter in another part of our paper.

South Carolina State Agricultural Society.

The editor of the *South Carolinian* attended the meeting of this society, which was held at Newberry Court House, on 30th and 31st July last. From his account of the meeting we learn that the attendance of the members was not so numerous as could have been desired, but Newberry and the adjoining districts turned out in large numbers. On Wednesday, a Palmetto Banner was presented by the young ladies of the village to the McDuffie Artillery Company, commanded by Capt. J. F. Williams. Mr. Bailey at the same time presented to the company a Silver Medal, made by himself, emblematic of the Artillery service.

The Newberry and State Agricultural Societies were then convened, Judge O'Neal presiding, in the absence of A. R. Seabrook. At 12 o'clock the annual address of the Newberry Society was delivered by Maj. Henry Summer. The afternoon was occupied in reading reports. The Editor of the Carolinian says these reports are more substantial in their details than any he had before read, and then adds:

"Thursday was the great day of the Meeting, and the village and grounds appropriated to the stock show contained crowds of spectators. The young ladies presented fancy work, which would not have been out of place in the *boudoir* of a houri, and the mats and wreaths of artificial flowers were peculiarly charming, and seemed to supply the place of nature's rosy children, which the drought had banished from the gardens. The more matronly dames, "*the mothers of young Carolina*," exhibited their offerings of useful domestic silk, woolen, and cotton fabrics, and patchwork quilts and coverlets, which tempted the most staid and incorrigible subjects of *Bachelordom* into the untried ways of *Caudle-ism*. We fancy these same "*comforters*" had a warming influence on many stony hearts, and look forward to the fruits of their good examples, and their influence upon the rising populace of the country with great hopes.

"The cattle show was superb. Horses of all ages champed impatiently their restraining bits—from the fiery steed, who would have acknowledged the dominion of no one, save an Alexander, or a "*big nigger*," and who would have borne the Knight Templar, or hurried the chariot of the victor at the Olympic games in furious haste across the dusty plains, to the mild suckling colt of the last spring—asses that would have astonished the donkey boys at Cairo—mules of better quality and higher form than the sacred beast which bore the Andalusian Monk and the fair daughter of Boabdil across the hills of Estramadura—bulls that out-bellowed the most noisy of Bashan's bovine thunderers—cows with distended udders and glossy sides glittering in the sunshine—calves, as bread and graceful as a fashionable belle fresh from Madame Weaver's *magazine des modes*—sheep with richer spoils upon their backs than the "golden fleece" of Colchis, and swine which grunted in the luxurious superiority of hog aristocracy, generated by the consciousness of the *purity* of Berkshire blood, which coursed lazily through their stearine obstructed veins, pinguid in their sleek obesity—all these were there contributing their prosperous looks to sustain the drooping spirits of agriculture. Visions of sweet rides, butter and cheese, warm jackets, hams, and fat-gourds, swam before our eyes in gay and giddy trains.

"But all these sights vanished from the numerous audience, when the ermine was laid aside—Themis forgotten—and our friend Judge Butler gave his charge in the Court of Ceres to a sensible and intelligent jury of farmers. We have often listened to agricultural addresses, but have never received more good advice, at the same time being highly edified, than on that occasion. He was very happy in his delineation of the popular agricultural and educational fallacies which prevail amongst us, and as we were leaving the Church, we heard a venerable hard-handed father of the plowshare say, "That speech will do more good than any sermon ever preached in that pulpit." Our readers may look out for a treat when we publish it. The village of Newberry exhibited all the characteristic hospitalities for which it has long been famed, to the delegates and visitors, and we trust everybody went home from the Fair delighted, instructed, and highly pleased."

Distinguished Farmers.

In the July number of the Cultivator, we had the pleasure of directing the reader's attention to an account published in that paper, of the farm and the extraordinary management of Mr. Calhoun. We beg leave now to remind the reader of that account, and to request him to read, in connection with it, the accounts which we hereunto subjoin, of the farms of Mr. Van Buren, and Mr. Clay.

"We copy (says the *New York Farmer*,) the following 'Personal Sketches' from the *Burlington Gazette*, presuming that our agricultural readers are always interested with what evidently tends to elevate the scale and heighten the pursuits of the agriculturist; and we take great pleasure in holding up as model farmers, those who, after having presided in the halls of legislation, and occupied some of the highest places in their country's trust, have retired from the bustle and excitement of 'political life,' and as farmers and agriculturists, doubtless enjoy more happiness than their elevated offices ever afforded them:"—

There is nothing more instructive and salutary than the spectacle afforded to our young men, of those who have been eminent at the Bar and in the Cabinet, who have passed years in the midst of the fierce contests and engrossing excitements of political life, taking an active and prominent part in the improvement of agriculture and the useful arts, and exhibiting the spectacle of dignified retirement and profound enjoyment of the simple pleasures of rural and domestic life. Our country now enjoys many such examples. Mr. Clay's farm is one of the best managed in Kentucky, and he has done very much for the general advancement of agriculture in the West, by introducing improved breeds of cattle, modes of cultivation, &c. Mr. Webster's farm is smaller and less fertile, but is worth seeing. Jesse Buel, a printer by trade, after being for many years a leading political editor at Albany, became the model farmer and teacher of agriculture for an extensive region around him. And we are happy to learn, from the following article, that Mr. Van Buren is now pursuing the same path prosperously and happily. The following is from the Albany Cultivator:

Visit to Lindenwald.—We lately passed a beautiful summer's day in the vicinity of Kinderhook. Among other places of interest, we visited Lindenwald, the seat of ex-President Van Buren.

We found Mr. Van Buren at home, and accompanied him in a walk over the farm. When he entered on the occupancy of his place, on his retirement from the Presidency, it was much out of order; the land having been rented for twenty years, and been under cultivation for the period of 160 years. Several of the buildings had become poor, the fences were old and were rotting down, and bushes and grass of wild growth had taken possession of the farm. During the short time it has been under Mr. Van Buren's management, the place has been greatly improved, and a course is now fairly begun by which a handsome income may be derived from it. The garden and pleasure grounds have been enlarged and newly laid out—hot houses have been erected—and a large number of fruit and ornamental trees, shrubbery, &c. have been planted. The greenhouse contains a collection of exotic fruits and plants, among which were some fine grapes, just ripening. In the garden we noticed some fine samples of all the fruits of the season, and some of the finest melons we have ever seen (so early in the year) in this latitude.

Among the objects which give beauty and interest to the grounds, are two artificial ponds in the garden. They were easily made by constructing dams across a little brook originating from springs on the premises. Soon after they were made (three years ago) some fish were put into them, and they are now so well stocked with trout, pickerel and perch, that Mr. Van Buren assures us they will afford an abundant supply for his table. This is a matter well worthy of consideration. There are many situations where such ponds may be made; and with trifling expense, the luxury of catching and eating a fine trout or pickerel, may be had at any time.

Several of the fields have been enclosed with new fences, and several buildings erected, among which is a very tasty farm-house, and a barn calculated for storing 150 tons of hay after being pressed.

But perhaps the most important improvements which have taken place on the farm, have been made on a tract of bog land, thirteen acres of which have been thoroughly reclaimed, and are covered with luxuriant crops of grass or oats. Three years ago this land was worthless. It was first drained by ditches; the stumps and bushes were then cut out and burned, and the ashes spread on the land. It was afterwards sown to grass—using a mixture of timothy and red-top seed—3 pecks to the acre. The whole cost of reclaiming was $33 per acre, and the land will now pay the interest of a hundred to a hundred and fifty dollars per acre. In this Mr. Van Buren has set a good example, which we hope will be followed by the other farmers in the neighborhood who have lands similarly situated.

The potato crop is one of considerable consequence on his farm, as well as on others in the vicinity. Mr. Van Buren raises the variety called Carters, produced from the ball a few years ago by the Shakers. He considers these by far the most profitable kind known. They yield well, and their quality is thought equal to any. Mr. Van Buren assured us that all which could be raised would readily command fifty cents per bushel by the quantity in New York. All the crops appear to be well managed, and are promising. Leached ashes were tried here last season with excellent success. Great benefit has also been found from plowing in clover.

Mr. Van Buren keeps but little stock, a considerable object being the sale of hay. The management of the farm is under the immediate supervision of Mr. Van Buren, who finds in it a salutary exercise for the faculties of the mind and body—such a state as to be highly enjoyed. In his rural retreat, removed from the care of state, and turmoil of political wars, he

Now drinks the pure pleasure of a rural life.

Henry Clay and Ashland.—Mr. Clay's farm contains about eight hundred acres; and in all my wanderings, including even old New England, I have never seen the same number of acres in a body, as handsome, as productive, as well fenced, and as well cultivated. His wood land is cleared of all underbrush and dead wood—his fields are enclosed with good fences, with the top rails all on, and not a weed or a brier in the corners—his hemp fields, &c. prepared with the skill and care

of a thrifty farmer—and he has a ten acre lot of corn, upon which he has bestowed extra labor and attention, with the view of obtaining the premium. Then there are his fine blooded cattle, sheep and horses, apportioned off into lots, according to age, and the use and purposes for which they are designed. Indeed, there is no spot in or about his residence or farm, that will not furnish evidence of his being a thrifty, profitable, and practical farmer. True it is, that I had read and heard much of Mr. Clay as the "Farmer of Ashland," but I regarded him as what is termed a "gentleman farmer"—as one who had a farm, but knew little and cared less how it was cultivated. But let any one walk with Mr. Clay over his broad acres—notice his intimate knowledge of everything pertaining to farming—hear him relate how he prepares and improves his lands, changes his crops, improves his stock, and yearly renders more and more productive and profitable his extensive plantation—and he will then see with his own eyes, that one of the best practical and most useful farmers in this or any other country, is Henry Clay, the Farmer of Ashland; and he will also see and learn that the best butter and cheese in the Lexington market are made by Mrs. Clay, the wife of the Farmer of Ashland.

Mr. Clay grows large quantities of hemp, and is connected with a son in a hemp manufactory.

Such is a brief descriptive outline of Ashland, as it was last April.

Mr. Clay's house is a handsome and substantial edifice, the main body about 40 feet by 50, with wings of proportionate dimensions. It stands in the midst of a profusion of venerable forest trees, evergreens, and shrubbery, upon a gentle elevation in the center of a lot containing about 50 acres, and is some 40 rods from the road. A serpentine carriage way leads through the grove to the house, and numerous pathways, tastefully arranged, studiously preserved and improved, beautify his extensive grounds. His house is plainly but well furnished, containing many choice and valuable evidences of the respect and affection of his countrymen. Then there is a stone cheese-house and stone butter-house, Ashland being celebrated for the quantity of the butter and cheese made thereat. His chicken-house, dove-house, stables, barn and sheds, are all in perfect repair, spacious, neat, and in order. His fruit and vegetable garden contains about four acres, and in its arrangement and cultivation I saw Mrs. Clay giving personal directions. There is also a large green-house filled with choice plants and beautiful flowers.—*Cleveland Herald.*

Horticulture.—The accomplished Editress of the Boston Transcript, recently confined to a sick room, in relating some incidents connected with a visit to the Horticultural Hall opened in Boston on Saturday, says:

"It was a day of delight to us, although *pain* would have kept us rivetted as in iron. The floral chain however was the conqueror, and the aroma of 'nature's jewels,' was like the 'infallible pain extractor' advertised as a wonder in all the newspapers. One of our New York contemporaries the other day found a business friend *in Wall-street (!)* happy in contemplation of some fresh flowers he was placing in a tumbler, and on expressing his astonishment, the merchant calmly looked up to his visiter, with this salutation: "Ah, how d'ye do? I am trying to forget for a moment the turmoil around me, and enjoy these beautiful creations of an Almighty hand. Have you ever observed that the pleasure derived from perfumes and music is of all our physical enjoyments the most perfect? If enjoyment is heightened in proportion as we approach the spiritual, what must be the blessedness of the good, when the physical is shaken off entirely, and this mortal puts on immortality!'"

A glorious thought amidst the trials of business! The merchant was *right*, and we would rather enjoy the after-blessings of such thoughts, than to inherit all the gold of Ophir, which is too apt to *buy the soul* and keep it wedded to mortality.

Insects have great powers of smell, and most of the essential oils of plants are offensive to them, and may thus be used to exterminate them.

Original Communications.

Bermuda Grass.

Mr. Editor:—Is it not astonishing how doctors *will* differ? There is not much danger, however, of their killing the patient, in this instance, if we may judge from the experience of one of your correspondents. One would think that a covering of green pine brush waist deep, a growth of briars so dense he could not stick a butcher's knife into it, or a closely jointed plank floor over it, would destroy anything, even bitter coco!

But there must be some mistake here. On reading the article in question, the first time, and finding the writer speaking of Bermuda grass growing luxuriantly in a dense thicket, standing "from knee to waist high, and as thick as grass gets to be," I felt really pleased at the thought, that here was a grass that would prove of greater value to the South than even the Bermuda; but when I found him speak of stock eating broom sedge in preference to it! that was a damper. The gentleman can never have seen what we here call *Bermuda grass.* It covers the commons of this town and Natchez, both of considerable extent; of course, there are parts of the common set in other grasses—broom sedge and Natchez grass, which is almost as rough and coarse, being the most common. The Bermuda sod is *always, and under all circumstances*, unless, perhaps, where it has had a rank growth, encouraged by the wash from a sewer, stable yard or such place, *closely grazed*, whilst the other growth is comparatively untouched. And it is a notorious fact, that wherever there are moderately good ranges of Bermuda pasture, *the stock is uniformly fat.* As a hay-producing grass, it cannot be equalled. My little meadow here, though from situation and other circumstances, in a rather rough state, is at this time a sight that would gratify any intelligent farmer. It cannot yield me less, rough though it be, than an average cut of three tons per acre of dry hay at this second cutting, and much of it will give me at the rate *of over five tons*, and I will get yet a third cutting.

That it is a nuisance in a cotton field in which cotton has been grown for seventeen years in succession, as is not at all uncommon, no one can deny; but that it can be kept under perfect check by "sowing the ground in small grain for several years in succession, (this, alone, I never recommended,) or by cultivating the ground *in any other way*" is *not* a "notion founded on inexperience," notwithstanding your correspondent's courteous assertion!

How opposite is the experience of Mr. Felton given in the next article headed "Bermuda Grass." The grass he speaks of must be what we call Bermuda here. I look with interest for answers to P.'s inquiries. Had I leisure at present, which I have not, I could give him some information in answer, but must, for the present, defer it.

Let every man try this grass on a small scale and test the matter for himself; three or four years will do it thoroughly, and an eighth of an acre be scope enough, and that might be in some nook or corner whence it could not readily spread. As to its "ruining the country," there is but little danger of that. *At the very worst* it is not as troublesome as crab grass and tie vines combined! For my part, I would gladly run the risk of having it spread even to *an uncontrollable extent* if I were the owner of a worn, washed, hill plantation, with a comfortable house and improvements on it. That it improves the land is certain—that stock give it a preference and thrive and fatten on it is equally certain; it preserves the land from washing and makes it give a return in mutton, wool, butter, beef, pork, young mules, &c., such as it never gave in cotton or corn. Your readers may rely upon it, that I would be very unwilling to recommend the introduction of anything likely to prove injurious. And I would here repeat the caution I have often given, not to trust to any man's say so, but try every new thing in a moderate way. Take a piece of poor hill land and get a good covering of Bermuda grass upon it and try it there. Most of the planters of the South let all of their hill lands that will, and that too the cream of them, find its way to the ocean without making an effort to prevent it. They might surely risk a few acres of such in trying a grass that others have found so valuable. One of the very best farmers in Mississippi, a farmer and cotton grower of thirty years' experience, told me that when Bermuda grass first got on one of his plantations, he found it so troublesome that he thought his place ruined, but that he quickly found he could keep it under *sufficient* check by the use of oats, peas and pumpkins, to grow full crops of cotton without extra labor, and now he considers it invaluable, and has beautiful pastures of it.

Do not cease urging upon your readers the necessity of horizontal or *side hill ditches*. Procure and publish all the information you can, for and against, for I have no doubt you will find a difference of opinion and even of experience there too. If imperfectly and improperly done, they are *much worse* than useless, and had better be undone. Yours, &c.

Thomas Affleck.

Ingleside, Miss., July 15, 1845.

Bermuda Grass.

Mr. Camak:—I see in your valuable Cultivator a great many inquiries on the subject of Bermuda Grass, and well there may be. Some wish to know whether it is a profitable grass or not; others wish to find out the cheapest plan to get clear of it. Mr. Cunningham says in the May number, "I consider information on this subject of more importance to the agricultural interest of our State than any other, and if it can be given satisfactorily, the man who does it will deserve not only the silver cup, but the thanks and gratitude of our whole community." He says again, "I would as soon try to drown a fish by throwing him in the water, as to kill Bermuda Grass by never so much working in the sun."

I must beg leave, Mr. Editor, to differ with him entirely, and say that in my humble opinion planting hoed crops is the surest and the *only* way to destroy it.

I had a field of about twenty acres spotted over with it, and I determined to destroy it. I planted it in cotton six years in succession, and worked it so frequently that the land was injured, but the Bermuda was killed. I have a field of fifty acres or more that was matted over with it, and thrown out in consequence of it. I cleared a field by the side of this Bermuda field, and to have a straight fence, I took in three or four acres of the Bermuda with the new clearing. Some of my friends told me that I would scatter the Bermuda over the new ground and ruin it. I took the precaution, however, to cultivate it by itself. This was in the winter of '41 and '42. I planted it in cotton three years, and now I cannot find a sprig of the grass in it. In the winter of '43 and '44, I took in twelve acres of the old field, a solid turf except about half an acre. Last year I planted cotton on it and made a good crop. I have it in cotton this year, and I will venture to say there is not a handful of Bermuda on the twelve acres. What remains may be found around the small stumps, which I expect to exterminate by the time I am done working it.

I took in thirty acres more this year which were entirely covered with Bermuda except two or three small spots, about an acre and a half in all. I planted it in cotton, and as I have had such a favorable spring for killing it, I think I shall succeed in destroying it almost entirely this year.

I will now detail my plan for destroying Bermuda Grass. I commence about the first of December, for that is as soon as we can get the top killed by the frost in this part of the country—set fire to it and burn off clear so as to have as little stubble to contend with as possible. I then break it up broadcast with a turning plow,

being careful to take no more land than the plow can turn *well*, not more than half the width of the plow, and no deeper than just to get beneath the roots. I let it remain until there comes a freeze. About the first of January I lay it off three and a half feet with a scooter plow, and ridge it up with an Allen plow, running four furrows around each scooter furrow, then I re-bed it once a month until planting time, throwing the ridge back in the middle each time, and exposing a fresh quantity of roots each time to the action of the cold and wind, being careful each time to plow no deeper than at first. The last time I re-bed it is at the time I intend to plant. Three furrows to the row will make the bed, the last furrow with a good size shovel plow; then I sow the cotton seed down in the middle and cover with a board. My reason for this is to get the cotton in the clearest place of Bermuda. I plow it the first time with an Allen plow, running with the bar next the cotton; then the hoe comes and takes away all the Bermuda roots from the cotton. The second time I run a short scooter as near the cotton as I can, very shallow; let it stand a few days, then plow out the middles with a shovel. After this, I hoe before plowing, so that the hoe hands can see and get out every sprig that is up. If I can get a dry month in May or June, I work it once a week. Whoever bestows this quantity of labor on a Bermuda field is sure to conquer the monster, and as I said before, I believe this is the *only* sure way to do it. He that undertakes it must wage a war of extermination. Anything short of that will only allow it an opportunity to take deeper root. I am convinced that shading will not destroy it. Mr. Pitts, in his essay on Bermuda, has thrown light enough on that subject to convince the readers of your valuable work that shading will not do. I concur with him in opinion.

One of your correspondents wishes to know if it will not be a good plan to plant Bermuda in order to improve land. My opinion is, that if the roots could be turned under and decomposed without so much work and exposure to the sun and atmosphere, it might improve the soil; but being so much exposed evaporates the strength of it, and working the land so frequently injures it. I have thus given you some of my essays in Bermuda killing, and if you think them worth a place in the CULTIVATOR you may hear from me again. In the meantime, if you wish certificates for my statements, they can be furnished at any time. JOHN W. RHENEY.

Burke County, Ga., July 31st, 1845.

Bermuda Grass--Raising Sheep.

MR. CAMAK:—I had intended to answer, inquiries, in the July number, by "P." of Monroe, Walton county, which he proposes to you or me, or any others, relative to Bermuda Grass; but my engagements have been so great, that I could not then do so. He asks, first, what would be the expense of enriching land by planting this grass, and turning under, compared with the outlay required when leaves and other like substances are used? His several other inquiries are of kindred character, all wishing to know the cost and labor of enriching lands by this grass, &c. Now, in reply to all these, in one sweeping sentence, I advise "P." if he has not this grass on his farm, to be sure and not introduce it. I have said, in giving you some of my experience with this grass, in your May number, that if we could kill it, I would consider it a great improver to our poor, old, worn-out lands, and that it would be to us, what red clover is to the North; yet I did not intend to encourage any planter to get it, who had it not already on his premises. Let then, "P." resort to any other mode of manuring or plowing in green crops, to improve his lands, rather than by the Bermuda, till we, who have it in such profusion, can give him some less expensive way of getting clear of it, when we want to put the ground in cultivation with other crops. If he has it, we invite his co-operation, in finding out the secret, of how we shall give the death-blow to this vegetable, which, I must think, has one life more than the cat, which it is said, has nine; for I must think, I have killed some of mine, nine times, and I find it alive yet, which at least gives it ten lives. But, without jesting, the subject of Bermuda Grass is becoming a grave question, and it is what we have yet to come up and meet as tillers of the soil, and learn to conquer, or it will conquer us.

I am glad to see so many pieces on the subject of this grass, as in less than ten years, it will be spread over this whole country; and the sooner we learn to manage it, the better. It is to be to us, no common friend, or the most deadly enemy, and it surely behooves us to know in which of these characters to view it.

And now, while I have pen in hand, let me make amends for having done so little for the "SOUTHERN CULTIVATOR," by calling the attention of every member of the community, who has a piece of land as large as a garden, (and if indeed he has none, he can be re-paid by other matter of general interest) to what "Jethro, of Reclusa" (see August No. page 123) says, of the utility of this periodical. And why should it not have its hundred subscribers, where it now has one? I subscribe to all he says, besides paying my dollar, which is, in all conscience, cheap enough; and it shall have my thanks to boot, if its able conductors or its numerous contributors, will only aid me in managing my Bermuda Grass.

But again; this same "Jethro" calls upon you, Mr. Camak, for your aid, (as well as the Editorial corps of the State,) to a subject, "the success of which, will enhance one of the dearest interests of Georgia." "Will our next Legislature not grant us a law for the encouragement of the raising of sheep, and the production of wool?" I call upon all whom it may concern, (and who is there that is not concerned) to aid and strive to get the Legislature, in addition to the wolf law, which I believe now exists, to at least pass a *Dog Law*. Here lies the root of all the mischief, and the preventive to our having, "in less than five years, sheep upon a thousand hills." But for this, I would add, we would have our thousands of sheep, upon our tens of thousands of hills, and as many valleys. I have tried it, and thousands of others have tried it: but who can raise sheep, while every man, boy, and negro, has his dog running at large, that will kill as fast as you raise. Then let the Legislature say, no one shall have a dog, unless it be confined in his yard nights, as well as day; for night is the time the damage is done. Or require a tax of ten dollars, on all over one a man has or permits to be on his plantation, with a fine of five dollars for every sheep such dog kills, on the owner of the plantation or premises to which said dog belongs.

Yours, truly, J. CUNNINGHAM.

Greensboro', Ga., August, 1845.

Agricultural Tour--The Growing Crops.

MR. CAMAK:—I promised you in my last, before setting out from Alabama, that I would give you such information on the subject of agriculture as we might be able to get on our tour to the West, East, and North. In compliance with that promise I now attempt to say something of what we have seen and heard of the growing crop. We left Eufaula on the 4th June. The Spring had been cold and dry. The crop of corn was suffering for rain and warm weather, as well as cotton. On reaching Montgomery county, we were pleased to find the corn crop promising a large harvest, so far as we examined. We spent several days with my friend Dr. S. C. Oliver, who is quite a large cotton planter. He has upwards of one thousand acres in cotton; near half that number of acres in corn, and a fine oat crop. His entire crop looked well. To have been, for the last sixteen years, engaged in politics, he has certainly accomplished much as an agriculturist. Circle-Wood, the residence of Dr. Oliver, of Montgomery, Ala., is a most beautiful place. The lands being rich, if this gentleman would devote his talents to the improvement of his fine farm, he would have one of the best plantations in the State. We visited the farm of Mr. Abner McGehee. This enterprising gentleman, who has done so much for the country in building up the rail road from Montgomery to West Point, owns a large and well cultivated farm. We found Mr. McGehee planting a mixed crop; that is, corn and cotton planted together, the rows running in the same direction. Both corn and cotton looked well when I saw it, on the 7th June. The cotton crop on the rich prairie lands of Montgomery, is said to be a very uncertain crop. This is the reason given for mixing it with corn. I rode over the crop of Judge Bibb and found his farm in a high state of cultivation. This industrious gentleman pays great attention personally to his Agricultural operations. Judge Bibb has done much in the way of ditching. He has a number of ditches running in every direction so as to save his land from washing and secure a good crop the wettest season.

In passing down the Alabama river, I conversed with several planters residing on the river, who informed me that the crop of cotton of the present year was equal to the crop of 1844 in point of quantity of land planted, but that owing to the cold dry spring it was by no means promising, having been much injured by the lice.

In passing up the Mississippi river after leaving New Orleans you are delighted with the beautiful farms in the State of Louisiana. These sugar plantations present a most splendid appearance. The entire land is in a high state of cultivation, and beautiful residences, surrounded by negro cabins, all painted white, gives the appearance of handsome villages. The first hundred miles after leaving New Orleans we were so fortunate as to pass up in the day time. I say fortunate, as it is so common for the boats to leave New Orleans so late as to prevent one's seeing this beautiful sight.

I have no space to speak of towns and cities; I will, however, say that St. Louis is the most growing city I have ever seen. The immense trade from that place is in tobacco, hemp, lead, cattle, coal, flour, pork, lumber, &c. We were informed by the farmers on board the steamboat that there was a considerable falling off in the cotton crop in Louisiana and Mississippi; that many of the farmers were turning their attention to the growing of Sugar, instead of Cotton. One of the large steamboats, I learned, had gone down loaded with machinery from Cincinnati for the preparation of sugar.

We left the Ohio at Evansville, Indiana. Here we took stages, and had an opportunity of looking out upon the growing crop; and this being my first visit to the far West, I was, as you may suppose, much interested with the manner of cultivation. We travelled the first day fifty miles, through the State of Indiana, to Vincennes. We found the corn and wheat crop, which is the principal crop of this country, much injured by the late heavy rains. Indeed, the entire country, lying on the upper Mississippi and Wabash, has been flooded with rain for the last month. We found the richest lands, as we passed on, in the hands of the most slovenly and careless farmers. The Wheat crop being generally cut, was said to be much injured by the vast quantity of rain. We reached Vincennes at night, and found it a beautiful town on the bank of the Wabash. We crossed the Wabash at this place, and travelled some eighty miles, in the valley of this river, over the richest country of land I have ever seen. You travel from morning until night over a perfectly level country; scarcely a hill in the distance; the timber generally black walnut, beech, poplar, &c. You occasionally come to a large prairie of ten or twelve thousand acres. Here you find a number of families settled together, there being nothing to do on these prairies but break up the land, fence it in, and the first year you get from forty to fifty bushels of corn, and from twenty to thirty bushels of wheat to the acre. They plant the corn here four feet each way, and leave generally four stalks in a hill.

It appeared to me to be sowed rather than planted. In this State the wheat is somewhat later, and the farmers will be able to save it much better than those in Indiana, as the weather is pleasant at this time and dry. And notwithstanding the lands are so rich, you see but little appearance of prosperity; so true is it that where the Almigh y does much for man, he is inclined to do but little for himself.

I visited, a few days past, the extensive nursery of Mr. Curtis of this neighborhood. This gentleman employs ten hands in his nursery, sells yearly sixty thousand apple trees, all grafts of the finest kind of apples, and other fruits. He is making arrangements for raising shrubbery and flowers.

I visited a Col. Blackburn, of this neighborhood, and was highly pleased with his farm. He employs some 8 or 10 hands. His meadow land presented a beautiful appearance. He raises 2½ tons of hay per acre. He has 80 acres of this meadow set in timothy and clover mixed. It requires but one sowing in ten years. The stock of this gentleman is of the finest kind, all his cattle being the short horned Durham. They are fully equal to the cattle of Tennessee.

I have found two Agricultural works here. The Indiana Cultivator is a work lately started at Evansville. From what I have seen of Indiana, there is the greatest want of Agricultural works. The Prairie Farmer, published at Chicago, has entered its fifth volume and appears to be an excellent work, well adapted to this latitude, from what I have seen of it. There is such a diversity of soil and climate between this country and the south that a volume might be written. From what I have seen of Indiana and Illinois, although they have such immense bodies of rich lands, that can be bought at low prices, I would prefer the sunny South as a home, by far.

Thus, my dear sir, I have attempted to throw together a few scattered thoughts that you are at liberty to throw under your table or publish, as in your judgment may be most proper.

Your friend, ALEXANDER McDONALD.

Paris, Edgar County, Illinois, July, 1845.

Mr. Burke's Letter.

MR. CAMAK:—I hand you enclosed, the letter to which I referred, when in Athens. By calling the attention of your subscribers in this district to the subject, and requesting them to furnish me with the information sought for, by Mr. BURKE, we shall render important aid to him in the preparation of his report. I am very respectfully, your obedient servant,

Monroe, August 19, 1845. HOWELL COBB.

Hon. HOWELL COBB, Athens, Ga.:

SIR:—Will you have the kindness to furnish me with the estimate of the crops for the present season in your district, either personally or by the aid of others, with the causes of increase or diminution, and such other remarks as you may judge proper for the Agricultural Report for 1845.

Also, please state the average daily and monthly wages of labor (exclusive of board,) of husbandmen, and persons employed in the different mechanic trades, in your neighborhood,

N. B. Please return this by the 1st of December next. Specimens of rare seeds will be most acceptable for distribution, I have the honor to be, respectfully, yours,

Patent Office, May 12, 1845. EDMUND BURKE.

EGGS are exported from Cincinnati in great quantities. It is estimated that an aggregate of 2,176,333 dozens, or 26,115,996 eggs have been exported from or consumed there the past year.

ADDRESS OF DR. PHILLIPS,

Delivered before the Agricultural Society of Habersham.

DR. GEO. D. PHILLIPS:—*Dear Sir*—In obedience to a resolution of the Agricultural Society of Habersham, we request of you a copy of your Address delivered before the Society on this day, for publication, hoping that others may enjoy the same pleasure in reading it that we did in listening to it. Yours, &c.,

WM. B. WOFFORD,
J. W. H. UNDERWOOD, } Committee.
JAMES R. WYLY,

Clarkesville, Ga., August 5th, 1845.

GENTLEMEN:—Your note, as the organ of the Agricultural Society, requesting a copy of the remarks I offered to the Society at its last meeting, would have been replied to sooner if it had been in my power. From an injury of the wrist, I have not been able to write, and but for its unreasonable length, should have sent you the original manuscript some days ago, but I could not think Mr. CAMAK would give it a place in the CULTIVATOR. In attempting to curtail its dimensions, I am sensible of having lopped off some of its most valuable limbs, and have some misgivings about sending it into the world in its mutilated form. Do with it, however, as you think proper, and accept my best wishes. GEO. D. PHILLIPS.

To Maj. J. W. H. Underwood, Gen. J. R. Wyly, and Gen. Wofford.

ADDRESS.

MR. PRESIDENT:—As I flatter myself our Society is destined to a long life, and as I may from time to time desire to say something on the various subjects connected with agriculture, I will, on the present occasion, commence at what I consider the true starting point, and begin at the beginning.

I lay it down as a proposition, sir, that cannot be successfully controverted, that any and every system of farming is defective, unless it is founded on a correct appreciation of the nature, the character, and the constituents of the soil. I use the term soil, as synonymous with earth, and not in its common meaning as applied to one or two inches of the earth's surface.

The soil or earth of the United States, indeed of the whole globe, might with propriety be divided into classes, corresponding to the primitive, transition, and tertiary divisions of our globe, and would be found to contain more or less of those salts and alkalies peculiar to each. We are here, sir, located in a primitive region, and our soil or earth is made up of the debris or disintegration of granite, gneiss, mica slate, sienite, argilite, and the numerous combinations of these. Our soil contains only a trace of calcareous matter, and so small a proportion of vegetable extract that it must be regarded as a poor soil. I am aware that we have it from high authority, recently sanctioned by two of our eminent citizens before this community, that the upper part of Georgia, embracing Habersham county, is, all things considered, one of the most desirable portions of the United States. Sir, I have travelled from the Niagara to the Trinity, and from the Atlantic to the Mississippi. I have noted the character of the soil and its minerals wherever I have travelled. I have made comparative estimates of the advantages and disadvantages of districts, sections and States, and I do candidly think the upper portion of Georgia deserves to rank as one of the poorest. If man, sir, could have all his animal wants supplied by a salubrious air and pure water, then indeed would the region in which we live be a most enviable one; but, as we require food to recruit the waste of strength, and covering to protect and adorn our bodies, we could not, even if we desired to do so, disregard the injunction of Heaven, that man shall live by the sweat of his face.

In pronouncing our soil poor, Mr. President, I desire to be understood as saying, it is deficient in what some writers call humus, some geine, and others vegetable extract; and likewise deficient in lime, and every other calcareous matter. Let these be supplied in sufficient quantity, and I believe the rolling lands of Habersham county would be equal to any, at least of granite formation, in the world. Now, the indispensable requisites of a good soil, sir, are, clay, sand and silica. The two first in about equal proportions, with from ten to twenty per cent. of the last. Such a combination makes a light, friable soil, sufficiently retentive of moisture, not liable to bake, and easily penetrated by the roots of plants; and it is in the power of every man, even those who know nothing of chemistry, to examine, and so far analyze his soil as to be able to decide correctly, if it possesses the requisite proportions of clay, sand and silica. This he can do by simply washing, boiling and weighing. The vegetable mould of our uplands is not more than from one to two inches deep. Let that be removed, and by means of a hoe or spade take from beneath any given quantity, say one pound of earth, put it into a pan and carefully wash it as we pan out gold. After all the clay (which is soluble in water,) and the fine silica is removed, the coarse sand will be left, carefully weigh this and note the quantity; then boil the water in which you washed out the clay, until it leaves in the vessel a mush-like paste, add more water, and after stirring up well pan out again more carefully than at first, and you will find in the pan perhaps neither gold nor coarse sand, but a fine brownish white powder or sand called silica, without which neither straw nor cornstalks can be raised; now carefully weigh the silica, and if you find you have 40 parts of clay, 40 of sand, and 20 of silica in the 100, you have a good soil, perhaps the best that nature or art has ever made, and every deviation from those proportions, showing either an increase of clay or sand, will make your soil less valuable and productive. It is, therefore, a matter of the first importance, that every farmer should examine his soil and ascertain its actual proportions of these indispensable materials. If he finds an excess of clay let him add sand, if of sand, let him add clay; either, alone, is unproductive, but blend them together in proper proportions, and by the aid of manure you have the finest soil in the world. I will now, Mr. President, offer a few views in support of this broad assertion.

Clay is necessary to the fertility of all land, by its attraction for water and the adhesion with which it holds it. This is so great that during the most intense drought, such as we now have, clay preserves that humidity which is indispensable to the nourishment and life of plants; and although the earth may be scorched with heat, and apparently dry as powder, yet the clay is still capable of transferring to plants some moisture, without which they could not live. Clay affords to the roots of plants a substantial support, and by its resistance prevents those roots from extending too far, thereby obliging them to throw out tufts of short fibrous roots, by which means each plant seeks its nourishment in a more circumscribed boundary, and consequently does not encroach upon the feeding grounds of its neighbor. Clay has a powerful attraction for oxygen, a material indispensable to the formation of carbonic acid; and lastly, it attracts nitrogen, one of the great nourishers of plants. These, sir, are some of the most valuable properties of clay, without which there could be no productive soil. But valuable as it is, it must not be in excess, as that would be highly injurious, from what I have said in detailing its good qualities. For instance, in periods of wet weather it becomes saturated with water which it retains too long, neither suffering it to percolate nor evaporate. In dry weather it becomes too hard and offers too great a resistance to the roots of plants. In frosty weather, owing to the quantity of water it holds, and which becomes converted into ice, it heaves, or, to use a common expression, it spews up so as to throw out or expose the roots of plants; and lastly, from its inherent qualities, it incorporates itself with the active qualities of manures and cannot be made to part with them so readily as the lighter soils do; and hence the fact well known to most farmers, that it takes a great quantity of manure to make clay land rich, but when rich, it holds it a long time. Nor should I omit here to say a few words relative to the difficulty and labor of cultivating a stiff clay soil. In wet weather you can neither plow, hoe, nor harrow it, whilst in dry weather it contracts and becomes so hard that it is with difficulty plowed, and is then broken up in clots so as to require a roller or a long exposure to rains and other atmospherical influences before it becomes pulverized, which often does not happen until the season is far advanced.

Sand is injurious too, when it enters too largely into the composition of soil, because it is not sufficiently retentive of water, but allows it to evaporate and drain away, carrying off with it the fertilizing qualities of the manure. Nor will sand, to any extent, combine with the humus or vegetable extracts, or absorb carbonic acid or nitrogen from the atmospheric air. Neither will sandy soils bear frequent cultivation, as it destroys all coherence and thereby impoverishes. And lastly, by being a good conductor of heat,

sand transmits the influence of severe cold or intense heat to the roots of plants, thereby subjecting them to hazard and injury. From these well known, but imperfectly considered facts, enforced by different writers of distinction, it is plain that a good and productive soil should neither contain an excess of clay or sand, and consequently our estimation of most lands should principally be based upon the proportions in which clay and sand are united in them. What those proportions are, I have already stated: 40 of clay, 40 of sand, and 20 of silica. These proportions, it is true, may be considerably varied and yet have a fine soil, provided the sand and silica predominates; but these should never exceed 70 parts in the 100, and even then, large quantities of vegetable matter become necessary and the manures are soon dissipated.

Now, sir, if nature has not given us such a soil as I have indicated, can we not make it? To do so may require much labor. It may take a great deal of carting and hauling, but when the work is done it is done forever. Most of the future labor, apart from the enclosure, will be making and applying manure, and as that may be applied in sufficient quantity, may we not calculate upon 60, 70 and 80 bushels per acre? If any one doubts it, let them make the experiment upon one acre or one half acre, and if the result should falsify my prediction, I hold myself bound to pay him for the full amount of his work. Our uplands, Mr. President, approximate a good soil, much nearer than do our valley lands; for, with the exception of a few fields, I know of no bottom or valley lands in the county which do not contain either a great excess of argillaceous clay or of coarse granite sand. There are only two fields within my knowledge in the beautiful valley of Naucoochee, two on Tugalo, and General Wofford's plantation on Broad River, that contain anything like the proper proportions of clay, sand and silica. If you were to examine them, you would find about one-half of our valley lands, provided they have been drained, to have a rich looking, black, vegetable mould, from three to five inches deep, and underneath a stiff, hard-pan, or argillaceous clay. This kind of soil, when fresh, will give, even under the most imperfect cultivation, 40 or 45 bushels per acre, but in a few years the soluble matter of the vegetable mould becomes exhausted, leaving nothing but a mass of inert, carbonized matter, which will not yield you, under the most perfect cultivation, aided by good seasons, ten bushels of nubbins to the acre. The land is, in common parlance, sour, dead land. Now, why is it dead? Why should it not produce your corn, rye, oats or other grain? Examine it with your pan, and you will find only 4 or 5 per cent. of clay, about the same quantity of sand, and still less of silica. All else, the great mass, is inert, carbon zed vegetable matter. There is nothing to fix and support the roots—nothing to attract moisture, carbonic acid or nitrogen—no soluble, rich juices to nourish a plant, and no silicate of potash, without which, neither wheat, straw nor cornstalks can be raised. But I may be asked how these lands for a few years produced such enormous crops without those proportions of clay, sand and silica, for which I have contended. I will tell you why. For a few years, the mass of vegetable mould possessed cohesion enough to fix the roots and retain and transfer moisture. This supplied the place of clay. The porous nature of the soil, permeable to atmospherical influences, and easily penetrated by the roots, supplied the place of sand. It possessed silica enough to glaze the stalk and blades for a few years, and it was vastly rich in humus or soluble geine, as nearly the whole mass was made up of decayed and decaying vegetable matter, and hence the enormous crops until the soluble geine or humus was exhausted. That these are truths, and not visionary speculations, I will now prove. Take a given quantity of this (so called) dead land, and spread over its surface fifty bushels of lime or double that quantity of unleached ashes, early in the spring. Harrow it in; and at the proper time sow down in oats, barley or wheat, Siberian or Italian, plow shallow to avoid sinking the lime or ashes too deep, and you will find this dead land resuscitated. It was not actually dead, but in a state of torpor only. The lime or alkali has waked it up, and you will find your labor and nursing rewarded by a heavy crop. I am sure I need not tell you how this has happened. It was the chemical action of lime upon inert vegetable matter, and the formation of rich soluble matter to nourish the plants. It likewise converted the remaining silica into silicate of potash to glaze the stalks and blades.

But I may be asked again, if the occasional application of a few bushels of lime or ashes will keep these lands thus productive? I answer, no. They are radically deficient in clay, sand, and silica, and a new soil has to be formed or you must abandon them. And the only question is, which will you do? Can any farmer hesitate? The whole substratum or subsoil is adhesive clay, or alumina. You have that at least in superabundance, and by the plow you can bring up to the surface what you want and no more. You have somewhere, not far off, beds of sand or sandy clay that can be hauled on and spread over the field in quantity nearly equal to what you have brought up by the plow. This, together with the small quantity of sand and silica contained in the alumina or argillaceous clay, will make about the right proportions. Let this be done in the fall, and by spring, from the action of frost and other atmospherical influences, you will find the whole in a fine, well pulverized state. You will now have all the elements of a good and durable soil, and one, by the aid of manure, vastly productive. We have, sir, in this and the adjacent counties, a considerable quantity of such land as I have been describing. It comprises, perhaps, one-half of the flat land on Soque, much in Naucoochee and Duke's Creek valleys, some on Beaver Dam, and a portion of your farm at Currahee, and I cite you to all that part on which you have grown such heavy crops of oats and such light crops of corn. There is, however, considerable variety in these lands, even in the same valley, dependant upon variations in the quantity of sand and silica they may contain. Those belonging to you to which I have alluded, contain a fair proportion of silica, and hence the good crops of oats grown on them. Of this I will satisfy the Society when I close, by exhibiting specimens from my own farm.

Accident, rather than science, led me some years since, to investigate the character of these lands. For a few years, after reclaiming my bottoms, they yielded me heavy crops, as much as 56 bushels of corn to the acre. But they soon began to fail, and, at the expiration of seven years, would not pay for cultivation. About that time, having brought the adjacent high land, which was poor, into cultivation, a small quantity of the clay and sand was washed down on the valley, and I noticed an obvious superiority in the crop, as far as the clay and sand had been carried. The next year, the land was in corn, and I was still more forcibly struck with the improvement. No manure had been applied to the hill-side; it was naturally poor and gravelly, and it was plain that the luxuriant corn was not nourished by geine or humus. On what then did it depend? Clearly, sir, upon the accidental combination of clay, sand and silica. Many gentlemen present, must have witnessed similar results; and if they have, can more conclusive proof be necessary, as to what should be done? If it is, I have it at hand. When a portion of my valley land refused to grow a blade of oats, or a stalk of corn, as large as my thumb, I measured off three sections, or lots, of five roods square. On the first, I spread six bushels of lime; on the second, twelve bushels of unleached ashes; and on the third, ten heavy cart loads of poor sandy clay; and sowed all down in oats. The sections receiving the lime and ashes, turned off a pretty fair crop; whilst the clayed and sanded section was not worth cutting. The succeeding spring, I applied one cart load of cow-yard manure to each of the sections, and planted them in corn. The difference now in favor of the clayed and sanded lots, was marked from the time the corn came up, and made at least one-fourth more than either of the others. Now, sir, is not the reason as plain, as was the difference in the crop? The first year, the lime and ashes acted on the inert vegetable matter of the soil, and evolved nutritive juices to nourish the crop, whilst the clayed and sanded parts had no such aids. But the second year, when it had those aids, and a better soil, one made up of clay, sand, and silica, it far outstripped the others. After my valley lands had so rapidly and unexpectedly failed, I was on the eve of converting them into pasture. The soil still looked rich and black as ever, and why it should not produce, I could not conjecture. In this dilemma, I opened a correspondence with Judge Buel on the subject. He attributed the defect to an excess of humic acid, and advised the free application of lime. But that scientific farmer, and learned man, was mistaken. These lands, however, may contain some acid, but there is unquestionably a defect of clay, sand, and silica. The application of lime would have neutralised the acid, and as we have seen, elaborate some geine for a single crop. But sand and silica alone could give a soil to produce crops, by the aid of manure, forever.

I have already stated, sir, that the remaining half of our valley lands are sandy, and I might have said, contain a great excess of sand: for I do not know one plantation on Soque or Tugalo where there is not a great demand for clay, to increase the fertility of some parts of the farm; and I am convinced the owners of farms could not expend money and labor so advantageously in any other way to increase the productiveness of their land, as the transposition of clay to sand, and sand to clay. Let the experiment be tried on five acres, and I shall then feel satisfied it will be on five thousand. Is there a man present who cultivates a garden, and who exercises his judgment in its culture, but knows that the addition of clay gives cohesion to sandy soil, and that sand and gravel, when mixed with a clay soil, diminishes its tenacious property; and that these changes, thus effected, permanently increase the productive powers of both. If the opinion advanced by most of the writers on agriculture be correct, (and I think they are sustained by experience,) that the productiveness of a soil mainly depends upon its natural or artificial capability of retaining and transmitting moisture, by the agency of which nourishment is conveyed to plants, the necessity of adding clay to sand, and sand to clay, whenever there is a deficiency of either, cannot be controverted. And hence the necessity, in all our efforts to improve a poor soil, to examine it in connection with one that is rich. If the cause of sterility be owing to some defect in its constituent parts, such defect could be remedied.

We are here, sir, surrounded by beds of iron ore in every direction, and many of our soils may contain such quantities of sulphate of iron, as to be highly injurious; and wherever that is the case, the use of lime is indispensable; but on the subjects of lime, tillage, manuring, and hill-side ditching, I may say something hereafter. From what I have said, in attempting to point out the natural defects of some of our soils, and the method of permanently improving them, I hope it will not be inferred that I consider barn-yard and stable manure as superfluous. No one appreciates their advantages more highly than I do; but as I have now detained you too long, they must be reserved for a future occasion.

Speech on Agriculture.

Mr. Camak:—The following original speech was delivered by Mr. Alphonzo Rogers, Student of the Academy at Warrenton, Ga., on the night of the exhibition, 16th inst., which, by request of several citizens, I forward to you for publication in the Cultivator, should it meet your approbation. Respectfully, H. E. Morrow.

Warrenton, Ga., July, 1845.

Fellow-Citizens: In traveling over our State, we may be struck with many instances of prosperity and happiness, and many of decay and desolation. If the Indian of another century were to come from the land of the Great Spirit, and revisit these scenes of his former sports, he would be surprised at the changes which have taken place among his former hunting grounds. He would not merely behold the snow-white cotton fields, the rice plantations, and waving corn—he would not merely behold the flourishing towns and villages and splendid mansions, the rail-roads and improved navigation; but in the older counties, he would be surprised at old fields worn out and overgrown with pine, and the gullies formed by the rains of half a century. He might say, the pale face has cut down the groves, cultivated and impoverished the lands, and now nothing is heard but the sighing of the winds among the pines—nothing is seen but the tracks made by the rains among the fields. The observation of every reasoning and reflecting mind would respond to the sentument of the Indian. Now, what has caused this sad reverse? Why have many splendid habitations been deserted, and why do the owl and the bat revel in those

halls once vocal with the sound of mirth and prosperity? No more are heard the woodman's axe and plowman's song among the hills, once presenting the appearance of abundant vegetation, but now of red clay. The true cause, I think, may be attributed to the over-anxiety of the farmer to become rich, and to ignorance of the principles of agriculture as they may be applied to the soil of Georgia.

Almost every farmer uses powerful exertions to acquire wealth. No sooner is the return in money received for one crop than he makes his calculations for another. He is always straining and always in want of more. And as cotton has hitherto commanded a high price, he has cleared his land and made a continued succession of crops until it was impoverished and useless. Again the axe and the grubbing hoe have been heard in the woods, and the darkness of night been chased away by the burning of brush heaps—again the fields have become white with cotton, and the proceeds of it invested in the purchase of more hands or more rich land. Thus he goes on from year to year, without regard to the future condition of his farm, buying his hogs and horses from Kentucky, and his flour from the North, often using inferior implements of husbandry, until he disposes of that plantation, for which he paid thousands, for a few hundred dollars, and drags his family away from an abode always comfortable, often elegant, and endeared by all the associations of home and early days, and hastens to a western wild in order to plant more cotton. Many evils grow out of this practice; hence you find an unstable, fluctuating population, and the State in a few years loses its identity. The early habits of our youth may be corrupted in a strange and irregular state of society; that stability of character which all ought to possess may be lost, and the principal element of patriotism, the love of home, may be destroyed. Of what use are internal improvements—of the construction of railroads and canals, and the building of manufactories, if the soil, which is the foundation of all prosperity, is impoverished and rendered valueless.

We are ignorant, too, of the principles that lie at the foundation of agriculture. We are apt to imagine that it requires but little scientific skill to make a farmer. We follow in the footsteps of our fathers in farming, when we do not follow them in anything else. We traverse the land and navigate the ocean by steam. Did they do it? Improvements are daily being made in every department of science which they never dreamed of. But we have adopted the same routine in the practice of farming which they pursued.

It is a fact that corn, cotton and wheat are composed of substances essentially different from each other, and each of these should be planted in that soil which contains substances most favorable to their growth. And every practical farmer knows that it is improper to plant the same crop always in the same field. Air, sun and rain will not make good produce unless there be good ground. Whenever, therefore, the soil becomes defective towards the production of a certain crop, manures ought to be employed to supply the deficiency. As well might we expect cows to give milk and horses to be in good condition for work, without the food necessary for them, as the land to produce well without manure. This is the point to which the farmer's attention should be directed; and hence the necessity of a knowledge of the properties of the different soils—in short, of chemistry as applied to agriculture. I believe the farmer ought to be educated for his profession as well as the doctor or lawyer for theirs. Our teacher has proposed to introduce into his school the study of agricultural chemistry, and we ought to embrace the opportunity afforded.—There is an agricultural paper, edited by one of the most scientific and practical farmers in Georgia, which ought to be in the house of every farmer, and from which we may acquire much knowledge. Our county has honored the cause of agriculture by the establishment of an Agricultural Society, whose benefits I hope will be felt far and wide; and it is to be hoped that ere long the farmer will take that elevated position in society for intelligence, industry and skill in his profession, to which he is justly entitled.

ELECTRICITY.—A lemon tree has been made to produce several crops of perfect fruit in quick succession by the use of the galvanic battery.

Census of Hancock.

MR. EDITOR:—The Legislature of Georgia, at its last session, in making provisions for the taking of the census, *neglected* to require those to whom that duty might be assigned, to take also, at the same time, the Agricultural statistics of the country. Believing that such information would be valuable to our people generally, and desirous that it should be furnished, at least for Hancock, I sought and obtained from the Inferior Court the appointment, that the citizens of my own and native county might be informed, not only what they grew for consumption and for market, but also what they bought which they could have raised, and what they paid for it.

It has been the custom in Georgia to make cotton to purchase horses, mules, pork and flour, and from a people too that did not barter for any of our products. Nothing but our money would pay for their articles. That money never returned to us through any other channel, and of course such a trade has kept up a continual drain upon the country. The opinion has been prevalent among us that it was cheaper for cotton growers to purchase their supplies than to raise them. A single view of the case would satisfy any one that the policy is bad, even when cotton bears a fair price. When cotton is bringing a fair price everything else brings a corresponding fair price, or when cotton suddenly rises to a good price the rise of other articles is simultaneous with it. But when cotton falls, it takes a year or more, and sometimes two, for other articles to fall in the same ratio, and the farmer who has neglected to raise his own supplies, not only suffers by the reduced price of his cotton, but in having to pay the former or the same price for his supplies as when his cotton bore a high price. The result of my observation is, that the farmers who made a little corn, wheat, oats, pork or bacon, wool, potatoes, and occasionally a horse to sell, and not more than three bags of cotton to the hand, was usually the money loaner, while he who raised eight bales to the hand and bought his pork, horses, mules and flour complained most of the hard times, and not unfrequently was the money borrower to the tune of sixteen per cent.

The conclusion then is just, that if the farmers of Georgia had raised their own pork, horses, mules and flour, tanned their own leather, made their negroes' shoes, clothes and blankets, they would be vastly better off than they are, and many would have been saved the mortification they have felt at seeing their property brought to the block, under the sheriff's hammer.

My object in laying the Agricultural statistics of Hancock before the public, is to arrest their attention on this subject; for what is true of Hancock, is true of the balance of the State, and the cotton growing region generally. The extent of this rule varies in the different sections of the cotton growing region, but everywhere its bad consequences are to be strictly measured by the extent, great or limited, to which the system is carried of raising cotton to purchase supplies. I am happy to believe that Hancock, in this particular, has materially changed her course. Her expenditures are scarcely the fourth of what they were a few years ago. Now, the principle part of the pork bought is by the inhabitants of Sparta, Mt. Zion and Powelton, and a portion of that supply is furnished by the farmers of the county, the source from which the towns should be entirely furnished; for thus the money which must necessarily be paid out by those whose occupations will not permit them to raise it, would be kept in the country.

I am happy also to find that our farmers are supplying our town with an excellent article of flour, and many of them are raising their own horses and mules. This I attribute to two causes: first, the very low price of cotton, and secondly, the influence of our *Planters' Club*, which has done much to improve the Agriculture of our county, and caused our citizens to think more correctly upon the subject of wearing out their lands to make cotton to purchase that which they could more easily make. I proceed to lay before you the census of Hancock, the quantity of crops and the amount of money laid out for supplies:

Number of free white persons 3,642.
Slaves and free persons of color, 6,407.
Free white males between 6 and 16 years, 605.
Free white females between 6 and 15, 504.
Slaves, 6,348. Free persons of color, 59.
Deaf and dumb, 8. Lunatics, 5.
No. of bushels Corn raised in 1844, 362,856.
Bushels of Wheat do., 17,683.
Bushels of Oats do., 31,880.
Pounds of Ginned Cotton do., 3,826,892.
Pounds of Pork raised do., 1,491,460.
Pounds of Pork bought, not raised in the State do., 228,749.
Pounds of Flour bought, not raised in the State, 13,750.
Horses and mules bought, not raised in the State, from the 1st of April, 1844, to the 1st of April, 1845, 82.
Amount paid out for horses and mules, pork and flour, not raised in the State, for the year 1844, $13,205.

This statement approximates as near the truth as it is possible, unless every man had kept a strict account of what he had made.

From the foregoing statements it appears that Hancock raised by the last crop 3,826,892 pounds of cotton, which at five cents, about the average price received for it, brought into the hands of the farmers, $191,344.50. Deduct the expense of freight, storage, care, &c., at $4.25 per bale on 9,567 bags, the number it would take to pack the crop, and we have the total necessary expense amounting to $40,657, which deducted from the amount received would leave in the hands of the farmers $150,685 of net profits. From this take $13,205, the amount expended last year for necessaries, and you have the amount of money left in the hands of the farmers in the county $137,480. It will be seen by this calculation that the amount expended for supplies is a little over 8 per cent. upon the net profits received on the crop. By applying this to the State, and taking only sixty-five out of the seventy-five counties in the State that grow cotton for market, and taking Hancock as the average, it will be seen that the net receipts of the State is $9,794,525, and the expenditure of the State for necessaries that she could make herself would be $858.325. What an amount for such an injury, as I think I can prove it to be!

Is there any one who will doubt for one moment that Georgia could raise $858,228 in pork, horses, mules and flour cheaper than to raise the money, by growing cotton to pay for it, to say nothing of the advantage accruing to our lands in the raising of those necessary supplies, and the actual independence of the people. But again, let us apply this calculation to the whole cotton growing region, and as the per cent. paid out by Hancock is perhaps below the average paid out by the whole, I will assume twenty per cent. as the average, and 2,400,000 bales as the number of the last crop; from which deduct twenty per cent., and you have left 1,920,000 bales. The question is, what increase of price would decrease of quantity give? There is no rule by which this question could be correctly answered, but supposing that 2,400,000 bales to be only a full and plentiful supply, and knowing that there is a daily increase in Manufactories, and a continually increasing demand for the manufactured articles, it is safe to say that the price would increase, at least in the same proportion as the reduction in quantity, and thus we would have the same amount of money in the country for 1,920,000 bags as we now have for 2,400,000. And it is probable that the increased price would in a year or two go to fifty if not one hundred per cent. It is easy to presume that a country would be more prosperous and happy to raise her supplies within herself than to purchase them from another, especially when it is remembered that the former course will keep an equal, if not a greater, amount of money among them at home, and at the same time

protect them from the disastrous vicissitudes of a foreign trade.

It may be asked, after all my positions are admitted to be true, how this is to affect the individual where there is no hope of arresting the selfish and heedless course of the cotton grower in his single undivided aim for quantity. The diminution of my crop, or of many crops, will have no effect on the market, but on the contrary will put the less amount of money in the pockets of those of us who attempt such a policy. Although I may be no worse off for raising my necessaries, and may have the same amount of money that I would have on my old plan of purchasing them, I cannot conceive that I am any better off?

To this it may be answered, that cotton is a very unstable article in its price, and governs the prices of everything else. When it rises, every thing rises simultaneously with it; but when it falls it takes two years for other articles to fall in the same ratio; for the very plain reason, that when cotton is high every energy is bent on the production. This creates deficiency in necessary supplies, for which, the demand being too great for the quantity on hand, the price necessarily keeps up. Now if you had raised your own supplies you would only suffer the diminution in the price of cotton, and if you have not, you will have to bear also the same price for these necessaries which you had to pay when yourcotton brought a good price. Again: by curtailing the cotton crop we would be enabled to improve our farms, so that in a few years we would be able not only to raise a full supply for our own consumption, but some to spare to neighboring towns, and our usual quantity of cotton also. And this is not all; for the increased value given to our laboring capital, in enabling it to yield a better interest, and the marketable value we may, from year to year, add to our lands, will be no small consideration if we should want to sell them.

Is it not better, yes, far better, for the farmer to make his own supplies and a little to spare, and then what cotton he can?

In conclusion, I call upon the farmers of my native county, and, if it would not be considered presumption, of my native state, to examine this subject with an eye single to their own interest, as well as the interest of the whole community at large, and that of posterity, and, as one man, to rally to the rescue of our long abused calling. It is time we had claimed for ourselves a more elevated position. It is time we had learned that this government is mainly dependant on and sustained by us; that all trades and professions are dependant on our success for bread—that posterity has claims on us which we should not disregard. Let us meet the State Agricultural Society by delegates from every county in the State, from county societies, and there unite our efforts in devising the ways and means for improving the Agriculture of our beloved Georgia. Let us petition the Legislature in mass, as one man, to give us aid in the accomplishment of so worthy an enterprise, an enterprise which aims to carry the lights of Agricultural science to its remotest and humblest votaries, and thus bless the world for ever.

Sparta, July, 1845. R. S. HARDWICK.

Inquiries.

1. When manure, especially animal ordure, and heavy compost are hauled out to the field, is it better, after covering it directly with the turning plow, to let the land lie fallow for one year before planting, turning in the weeds during the fall over the same field?

2. If manure thus once covered in be turned up to the surface, by the action of plowing in the weeds which afterwards sprang up, (on land one year to lie fallow,) would the fertile properties of the same evaporate? Or does manure in six months so *incorporate* with the soil as to escape all liability, or to any injurious degree, of evaporation, from a vertical sun or the air, of its strength?

3. Must not all deep plowing on hilly land be ever horizontal, from the great drain on the soil in heavy rains?

4. The act of putting sand on hilly clay land—is there any utility in this, if the sand then renders the land too susceptible of washing away—I mean in the fertile ingredients, and the sand itself—particles of silica being so apt to float on violent torrents or pass along the course of washings? J. J. FLOURNOY.

Wellington, August, 1845.

Sheep Raising—Information Wanted.

MR. CAMAK:—A communication in the last number of the CULTIVATOR, over the signature "Jethro," who promises to contrast the comparative merits of the different sections of Georgia for the raising of sheep, and the breeds best suited for those sections, has attracted my notice. As I wish to engage in the business of sheep raising, I feel a deep interest in hearing from "Jethro" at his earliest convenience, and ascertaining his opinions as to the breeds that would best suit the different sections of Georgia, and where they can be procured; and further, to have his views as to the best management of sheep. I make these inquiries in order to get correct information on the subject, hoping you will excuse me for them.

Respectfully, RAYTOWN.

Agricultural Meetings.

Georgia State Agricultural Society.

In accordance with a resolution passed at the organization of the Association in March, the following gentlemen have been appointed by the President on the several Committees, viz:

On the Agriculture of Georgia.—Wm. Turner, of Putnam; B. S. Jordan, of Baldwin; Joseph Willingham, of Oglethorpe.

On Grains.—R. S. Hardwick, of Hancock; Richard Rowell, of Baldwin; James Grubbs, of Burke.

On Stock.—Miles G. Harris, of Hancock; S. Grantland, of Baldwin; J. M. Adams, of Putnam.

On such plants as may be profitably introduced, and which are not now cultivated.—Iverson L. Harris, of Baldwin; Eli H. Baxter, of Hancock; Allen Inman, of Burke.

On Manures.—Wm. Farrar, of Putnam; John W. Moody, of Oglethorpe; Isaac P. Whitehead, of Hancock.

The annual meeting will be held in Milledgeville on the 2d Monday of November, when reports from the several Committees will be expected. J. R. COTTING, Cor. Sec. A. A. G.

Milledgeville, August 5th, 1845.

Agricultural Meeting in Clark.

At a meeting of a portion of the citizens of Clark county, held in Watkinsville, on the 5th of July, for the purpose of organizing an Agricultural Society, the Rev. JOSHUA N. GLENN was called to the Chair, and JOHN H. CHRISTY requested to act as Secretary.

The following resolution was offered by G. B. Haygood, Esq:

Resolved, That in our own opinion the interest of the country calls for the formation of Agricultural Societies in the various counties of the State, auxiliary to the State Society at Milledgeville.

Which, after a few forcible remarks, setting forth the advantages arising from such organizations, was unanimously adopted.

On motion, it was

Resolved, That the Chair appoint a committee of three to prepare for the consideration of the meeting a plan of organization for the Society.

Whereupon, the following individuals were appointed, viz: G. B. Haygood, Esq., Maj. Thomas Mitchell, and Richard Richardson, who having retired a short time, reported the following

CONSTITUTION.

ART. 1. This Society shall be called the Clark County Agricultural Society.

ART. 2. Its object shall be, to collect and diffuse information concerning Agriculture and its kindred arts; and to encourage and improve the same amongst ourselves.

ART. 3. Its officers shall be a President, five Vice-Presidents, a Secretary, and a Treasurer, who shall be elected annually by the Society.

ART. 4. The President shall have power to appoint all such committees as the Society shall, from time to time, deem necessary, for the promotion of the objects of its organization, and to fill the vacancies in all the offices below him till a regular meeting.

ART. 5. There shall be an annual and quarterly meetings of the Society, at such times and places within the county, as may be determined on by a vote of the Society, or established by its by-laws.

ART. 6. The President, or in his absence either one of the Vice-Presidents, may call an extra meeting upon the request of five members.

ART. 7. The Society shall hold an annual fair for the exhibition of such products as it may think fit to encourage.

ART. 8. The Society shall pass such by-laws as it may deem necessary for carrying out the objects of its organization.

ART. 9. Five members, including two officers, shall constitute a quorum to transact business.

ART. 10. This Constitution may be amended by a vote of two-thirds of the members present at any regular meeting, notice thereof having been given at a previous meeting.

ART. 11. Any person may become a member of this Society by paying the admission fee, not less than one dollar per annum, and by subscribing this Constitution.

Which, after having been read, and slightly amended, was unanimously adopted.

After the adoption of the Constitution, the meeting, on motion of G. B. Haygood, Esq., proceeded to the election of officers—whereupon, the following were duly elected for the next twelve months.

President—James Camak, Esq.

Vice-Presidents—Rev. J. N. Glenn, Maj. Thos. Mitchell, Col. Samuel Baylie, Jno. Gordon, Wm. L. Mitchell, Esq.

Secretary—Sidney B. Payne.

Treasurer—G. B. Haygood.

After which, the following resolution was adopted:

Resolved, That the President, with two or more of the Vice-Presidents, be authorised to procure some suitable person or persons to address the Society during the week of our next Superior Court—and at all regular meetings of the Society.

On motion of G. B. Haygood, Esq.

Resolved, That the proceedings of this meeting be published in the "Southern Whig" and "Southern Banner."

The Society then adjourned to meet on Thursday of our Superior Court.

JOSHUA N. GLENN, *Chairman*.

JOHN H. CHRISTY, *Sec'y*.

Burke Co. Central Agricultural Society.

In compliance with a resolution passed at the last meeting of this Society, the following Standing Committees have been appointed, and will report to the annual meeting in January next:

On Corn.—Messrs. B. B. Miller, J. B. Jones, B. E. Gilstrap, Charles Whitehead, Ezekiel Williams.

On Cotton.—Messrs. James Whitehead, J. C. Poythress, John Carswell, Samuel Dowse, Wm. Sapp.

On Small Grain.—Messrs. John Whitehead, Mathew Carswell, M. P. Green, John Dowse, Edmund Gresham.

On Stock.—Messrs. A. J. Lawson, Alexander Carswell, H. V. Mulkey, A. H. Anderson, Gideon Dowse.

On Manures.—Messrs. M. C. M. Hammond, Wm. Byne, C. W. West, G. Skrine, Wm. Owens. GEO. W. EVANS, President.

COMPOST FOR WHEAT.—For every acre of clayey ground which you intend to put in wheat, prepare enough compost, as follows, to allow a dressing of ten double horse cart loads, say of 40 bushels each.

Take 10 loads of loam from the woods, or the same quantity of rich mould, or well rotted manure, 1 bushel of salt, 10 bushels of charcoal, 1 bushel of plaster, 10 bushels of ground bones, 10 bushels of lime, add 10 bushels of ashes. Let these be well incorporated together; after letting the whole remain a few days, turn over the mass, and, as mixed together, add twenty gallons of urine to each ten loads; taking care to sprinkle plaster over it as the operation is being performed. A compost thus formed, will comprise all the constituent elements which the wheat needs, either for the formation of the straw or *berry*, and will prove to be the means of greatly increasing the *quantity* and *quality* of the product of the latter, while it will also tend to maintain fertility in the soil for several years, and thus augment the yield of subsequent crops, whether they be grass or grain. The above would be an admirable mixture also for a corn crop.—*American Farmer.*

BEES generally eat more honey than they collect after the 1st of August.

"SHE'S NOTHING BUT A COUNTRY GIRL."

A young lady, daughter of an agriculturist, after having been introduced to a company of *professed ladies* in a neighboring city, heard one of them remark to the others in a low tone, accompanied with a scornful smile, "She's nothing but a country girl." Upon her return home, she sent the scornful Miss a note, which contained something like the following lines:

I know that I'm a country girl,
And more than this, I know
That such far rather I would be,
Than her I'm writing to—
For pride of heart, and scornful mien,
Detested are, wherever seen.

A country girl! and what is there,
So dreadful in the name?
Though "verdant," yet I've too much sense
For that to blush for shame;
For it will ever sound as well
To me, as that of city belle.

I would not change my country home,
Where nature's scenes o'erspread,
For one where earth can scarce be seen,
Or blue sky overhead,
For all the wealth and splendid din,
Your "languid beauties" revel in.

What think you of our mother Eve,
Who dwelt in Eden fair?
No luxuries which gold procures,
Or dainties nice were there—
And as there were no cities then,
A country girl she must have been!

I hope for this you'll not deny
Your ancient parentage;
Unless yourself from all our race,
You wish to disengage—
If so, I pray let old and young
Be now informed from whence you sprung!

But if, as still I apprehend,
You are a girl of sense,
And that it is from pride of heart,
You make such vain pretence;
Please know, humility of heart
Does to our sex new charms impart.

When next in some disdainful mood,
To say you are inclined,
"*She's nothing but a country girl!*"
This couplet bear in mind—
That scornful lips and haughty air
Ne'er made a homely face more fair. M. B.

VOL. III. AUGUSTA, GA., OCTOBER, 1845. No. 10.

AGRICULTURAL INSTRUCTION IN COMMON SCHOOLS.

PROF. JOHNSON'S SECOND LECTURE.

On Saturday, according to promise, Mr. Johnston delivered a second lecture in the same place, Mr. Taylor, of Duddingston School, occupying the Chair.

Mr. Johnston said—Gentlemen, at the close of my address to you yesterday, I told you that I thought that what I said would not possess the same weight, or appear to have the same importance to you as to the practical agriculturist, and that you could not by any means feel the like interest that I feel, because in all probability most of you are unacquainted with the way in which agricultural chemistry bears upon, and is advantageous to, the practical agriculturist of the country. It was for that reason that I offered to give you an exposition of most of the important points in the science—to give you a short sketch, a sort of bird's-eye view, of that interesting branch of knowledge, to induce you to teach which, I presented to you so many considerations yesterday; and I am confident that when you have formed an idea of the subject, you will find it most interesting, and one which will yield you great satisfaction and pleasure to become acquainted with. Gentlemen, there was a time when this hill upon which we now stand was nothing but a naked rock of lava. That old lava gradually decayed as modern lavas do, and crumbled down and formed loose matter on the surface, in which seeds of plants grew, died, and left their remains. Thus by degrees the soil accumulated to such as you now see on the surface of this rock, on which plants now grow. Such is the history of nearly all the soils on the surface of the globe.

Suppose you take a portion of any one soil and put it upon the end of a piece of metal, such as I am doing just now, and in any way expose it to the action of the fire, you will see that part of the soil will grow blacker at the edges; bye and bye that blackness will disappear, and the soil will assume a color more or less dark, according to the nature of the substances of which that which remains consists. If you take this portion of the soil before it is heated and weigh it, you will find that after it is exposed to the fire it is not so heavy as before. That portion of the soil which has burned away consists of the remains of those vegetables of which I have spoken; of those animals who have died and been deposited in the soil; and of the manures which have been applied by the farmer. Thus vegetable matter forms what is called the organic, and the other portion of the soil the inorganic matter. The quantity of organic matter varies very much—in some soils it exists to the extent of two per cent., in others 15 and 20 per cent., and in peaty soils sometimes as high as 70 per cent. If you take a piece of vegetable matter and burn it, such as this wood, you will find here, also, that a large portion will not burn away, but remains, forming wood-ash. It is the same, then, with regard to the plant as to soil—a part burns away and a part remains. If you look at the tables you will see that different plants have different proportions of inorganic matter—thus, meadow hay leaves nine or ten per cent. of incombustible matter.

Again, as to the animal substances, take a piece of muscle, dry and burn it, and you shall find that the greater part of it will burn away, which is the organic matter, the remainder being, as in the soil, and in the plant, the inorganic and incombustible matter. Now, one hundred pounds of fresh muscles contain phosphate of lime and other saline substances to the extent of one per cent. of incombustible matter. Thus, the three different substances, soil, vegetable and animal matter, consist of organic and inorganic matter; but there is this difference, that in the soil there is a larger portion of inorganic matter than in plants and animals—in the latter, the greater portion burns away.

I call your attention now to the inorganic portion of soil. By looking at the table you will observe that the inorganic matter consists of different substances, such as silica, which forms a very large proportion of flint; alumina, a substance which forms a large proportion of pipe-clay; oxide of iron, which is the rust of iron; potash, of which the potash you get from the shops may serve to give you an idea; chlorine, which is a kind of air; and then there is manganese, phosphoric acid, and carbonic acid. These substances are found in all soils, but not in equal proportions. You will see in the table before you the details of the constitution of a soil which would yield good crops for perhaps a hundred years. Were you to possess such a rich soil as that, and such soils are to be got in the virgin land at the Cape of Good Hope, on the banks of the Ganges and the Mississippi, you would always find that it would contain a notable quantity of all these different elements. In the second column of the table you have a list of the quantities of the different substances of a soil capable of yielding good crops, but which would require to be regularly manured. You will observe that opposite three of the substances the word "trace" is put, which means, that though the substance was not absent altogether, yet it existed in so small a quantity that it could not be weighed. In the rich virgin soil stated first, you observe that there is of lime 59 per cent., while in the second column there is only 19. Of phosphoric acid there is four in the one, and only two in the other. In the third column of the table is the constitution of a soil so barren, that though manured, it could not produce a good crop. You see that there is a great many gaps in the list; in short, there is only five substances which exist in anything like quantity.

So much for the substances which exist in all good soils; and you may be sure that if any soil does not produce a good crop, some one or other of these substances are wanting. The question then arises, how do soils come to have such different compositions as these? I stated to you how the crumbling down of rocks formed the soil along with the accumulation of organic matter in it; and if I had had time, I would have directed you to a geological map, and shown that in every country the rock on which the soil rests is different; and if it be true that the crumbling down of rocks forms the soil, you learn at once how soils must differ very much in their composition. In feldspar soils, of which rocks principally consist, you will observe only silica, alumina and a few others. A soil formed from this must therefore contain a large quantity of these substances which are on all soils, while it would be deficient in many others. As soils differ in this way, we are led to this practical question—how can we make this soil to be like that soil, or how can a bad soil be made equal to a good one? The answer is simply, that you must supply those substances which are wanting in the soil—you must supply as much potash or lime as are wanting in the third or poor soil, and as much lime and phosphoric acid as is wanting in the second, to make up all the constituent elements which exist in the first or rich virgin soil, and which are necessary to enable the soil to produce a good and profitable crop. This shows you the benefit of an analysis of the soil, by which a farmer is enabled to decide what the soil requires, and proceed accordingly.

I shall next speak of vegetable substances; and first, as to the inorganic part of them. If you take the ash which remains behind, when a plant has been exposed to the fire, and analyze it in the same way as with the soil, you will come to this result, that the inorganic part of the plant contains precisely the same substances as the inorganic portion of the soil. In the table on my right hand, you see the composition of a 1000 pounds of hay. The different kinds of hay have different quantities of the same substance, which substance is the same as in the soil. In reference to the ash of vegetables, 100 lbs. of wood would leave behind not more than a half a pound of ash. Perhaps you may be inclined to ask why, seeing that out of 100 lbs. one half pound only is ash, can that half pound be necessary for the existence of the plant, or is it rather merely accidental, and in no respect making any difference to the plant? No such thing, gentlemen. That half pound of ash is just as much an essential part of the plant as the 99½ lbs. which burned away. The same is the case with wheat, which leaves 2 lbs. of ash. I state these facts in order to bring you along with me in my exposition of the principles of the science, that you may see how I come to the conclusion, and which must be true, that the plant could not live—that it could not fulfil the purposes of nature, unless it contained this small quantity of inorganic matter. If you look to the table on the ash of hay, you will find there is an analogy between it and the soil. Red clover contains in one thousand pounds thirty-one pounds of potash; rye grass as little as nine pounds. Of phosphoric acid, rye grass contains one-third of a pound, red clover less than 7 lbs., white contains five, and lucerne 13 lbs. We learn, then, that these substances are present in different proportions in the ash of different kinds of hay, and from that we draw several important practical deductions. Let us inquire whence do the plants derive the organic and inorganic parts of which they consist. They derive the organic partly from the soil and partly from the air; the inorganic solely from the soil. In the air float certain proportions of all those substances which enter into the organic part, but none of those which enter into the inorganic part of the plant. Now, the different kinds of plants in the soil will materially affect its constitution, and have a remarkable influence upon that constitution. Suppose I grow lucerne upon the very fertile soil detailed in the table: as the lucerne takes out a large quantity of lime and of phosphoric acid, you will see that the crop would rob the soil of a large proportion of lime and of phosphoric acid, and that therefore it would not grow the same crop with that luxuriance which characterised it at first, because it could not supply with the same ease and abundance those peculiar substances upon

which lucerne lives more than upon any other. Take the ash of the different kinds of grain, and you will find that each in its own way affects the soil. Wheat, oats and rye, require a large quantity of phosphoric acid, and so if you grow wheat a long time in the same soil, it will draw out this phosphoric acid among other things, and thereby reduce its quantity. This is what is meant by exhausting the soil. If rye grass is the plant used, it will exhaust the soil generally, because it does not take away a great portion of any one of the substances. In the same way different crops make the soil poor; but if I take the same crop, say fifteen or twenty times, a practice which, as is well known to the most of you, existed not many years ago, it would by that time produce no crop at all.

The land then may be exhausted in two ways —generally of all the substances, and specially, of particular substances; and from this circumstance we are enabled again to make two or three practical deductions. In the first place, inasmuch as the soil contains a limited quantity of these substances, and inasmuch as different crops carry off different portions, you at once see why it is judicious to have a rotation of crops—that the longer the time is which elapses before you take a similar crop, the longer will the soil last and continue productive. A soil may produce one crop, when it cannot produce another. Let us inquire next why land is manured. The composition of the soil would tell you in the first instance, for it is obvious that manure is applied to restore those things which are wholly or comparatively wanting. Chemistry tells practical men how to renew their exhausted soil. Suppose that fifteen crops of oats have been taken off a piece of land, it will lose a large quantity of lime, phosphoric acid and potash, and in order to restore it you must supply the soil with those ingredients of which it has been robbed. Manure being composed of the remains of vegetables taken off the land, and containing all those things of which the plant consists, the farmer, generally speaking, is enabled by its application to retain the fertility of the soil. But then, observe you, he adds all those things which are required for a fertile soil, which may be a great deal too much, and may not supply an adequate abundance of that particular substance which the land actually requires, and thus a great expense is entailed which he may not be able to undertake, and thus the land falls short of that richnesss which he wishes, and which, at a less expense, he might be able by other means, under the guidance of chemical knowledge, to provide for his land. If the farmer knows chemistry, he will, at far less cost, and far more effectually, secure good crops.

I come next to the organic part of the plant. You observe, when I take this wheat flour dough and wash it in water, it diminishes in bulk, and the water becomes milky. The portion that remains, for it will not all wash away, is a sticky substance, and this is called gluten. If the water is allowed to stand a short time, the white will fall to the bottom and form starch. The flour is thus easily separated into two parts, the starch and the gluten. If lint or hemp seed is put into a press and squeezed, a large quantity of oil will come out, but not the whole that the plant contains, and this is the case with all seeds, more or less, though the fatty matter may not be so abundant perhaps as to produce oil by pressure merely. Wheat contains gluten to the extent of from 10 to 13 per cent.; meadow hay 40 per cent. of starch. Of fat, wheat contains from 2 to 4 per cent.; straw, sometimes 3 per cent.; oats, 6 per cent.; Indian corn, 9 per cent., and meadow hay, from 2 to 5 per cent. Thus the organic part of vegetable matter contains gluten, starch and fat.

I shall now make a few observations on the composition of the animal. Of what does the ash of animals consist? The body, you know, is composed of various parts—of muscles, fat, bone and other elements which I need not detail. Let us examine the composition of the muscle, and we shall find that it contains two and a half per cent. of phosphate of lime, and a third per cent of other saline matters. In bones you do not have all the substances which exist in wheat, but you have some of them, such as lime, magnesia, &c. In ten gallons of milk there is three-fourths of a pound of saline matter; so that if you take the composition of the muscle, of the bone, and of the milk together, you will find that animals contain the different substances which are to be found in the soil. Thus it is we learn the intimate connection between the composition of the inorganic matter of the plant, of the animal and of the soil. But where does the animal get this inorganic matter? They obtain it from the plants. In bone, six-tenths of the whole consists of phosphate of lime and magnesia. Now an animal could not support itself or walk about without some bone or firm substance to uphold it. It feeds upon herbage, which it must have, in order to obtain those different substances of which it is made up. But if the plant had no soda or magnesia, the bone could not be built up no more than the walls of this house could be erected without lime, stone and other substances. It is necessary, then, that the plant should have all these substances, in order to supply them to the animal creation—a purpose which it could not fulfill unless it contained all that is necessary to build up their bodies. And where does the plant get these substances? It gets them from the soil; nor can a plant live without them. And here we have a beautiful example of the provisions of nature, for a plant cannot grow, it cannot appear at all, unless it can acquire those elements, and that, too, just because, if it did live, it might indeed deck the surface of the earth, but it would not be able to feed animals, which is its great purpose in the creation. (Loud applause.) Thus a beautiful thread of philosophy pervades and connects all those different substances. Of what does the organic matter consist in animals? It consists of two parts, the muscle and the fat, and you will remember we have three things in the plant, fat, gluten and starch. If I take a piece of muscle and wash it, I shall wash out the blood and make it like the color of fat, and upon tearing it out it will be seen to be fibrous. When the fibre is analysed, it is found to be the same thing as the gluten in wheat. If you take the fat of animals and compare it with the fat in plants, you will find a remarkable analogy to each other, though they are not absolutely identical, and I believe they could very easily be converted into each other. The organic matter of vegetables contains the same substances of the muscle of animals. Vegetables contain a large proportion of that which will very readily form the fat of animals, the only difference being that animal matter contains no starch. Let us now see what is the purpose for which the animal eats its food. Unquestionably for the support of the different parts of which it consists. You see again what a beautiful connection exists between the organic part of the plant and that of the animal. The animal eats gluten in order to form the fibre. When I eat rolls at breakfast, I eat a quantity of gluten and starch, and that gluten saves the digestive organs the trouble of manufacturing gluten for the frame. Out of those rude elements which constitute the soil, and which float in the air, it is the duty of the plant to prepare those substances—those bricks as it were, to be carried away by the builder to fill up different gaps which are continually made in the body. There is a great difference between starch and gluten. That substance called nitrogen exists in the latter but not in the former; in the fibre, and not in the fat of animals. Thus nitrogen is obtained wholly from the soil, therefore it is necessary it should be in the soil. In beans gluten exists to the extent of 28 per cent. If, therefore, you or I eat beans we eat that which is capable of building up a much larger proportion of muscle in the body.

Again, if the soil contains a large proportion of gluten, beans will grow when no other plant would. Some animals lay on the fat very abundantly, and some, like myself, lay it on very sparingly. (Laughter.) If you can have an animal inclined to lay on fat feed him with Indian corn. There is an important difference between the composition of the vegetable and that of the animal; in the former there is gluten, starch and fat; in the latter, muscle and fat only. The lungs are a sort of carbonic acid manufacturers. The starch we throw off to the air, the plants suck in, and thus it is the leaves are continually in motion, beating against the air, forming a thousand little mouths which perpetually suck in the carbonic air which forms starch. A man throws off about seven ounces per day of carbonic acid. Thus it would not be enough to eat merely of fibre and fat, but we require to eat the vegetable substances which contain starch, gluten and fat, because the general purpose of nature is to save the stomach the trouble of manufacturing these substances for itself. The lungs might suck in the same as plants do, but such is not the order of nature, and it falls to plants to supply the deficiency. The stomach can build more easily from carbonic acid than it could from muscle. In feeding young stock the farmer must give as much as will not only supply the daily deficiency, but also supply an increase of muscle and bone. You all know that every part of our body is continually undergoing a change, and that a certain quantity of gluten must be eaten every day to supply it, and it is the same with young animals, and therefore they require an extra supply of the elements of muscle and bone, in order that they may increase in size. You may, by attending to the different qualities of the kind of food, make your animal either very fleshy, very bony, or very fat. Animals reject in dung and other excrements a great many substances, and as the plants contain substances which are soluble with water, it is of great consequence to take care of the liquid excrescences, and to mix it with the solid, so that the whole the animal ate may be preserved, which, being taken back to the soil, it is provided with the same substances almost forever. If you allow the liquid to run into the rivers, you bare the land of what the plant gets from the soil, and which the animal gets from the plant. When the animal dies, all those things which it got is returned to the soil, and thus the same revolution goes on from the soil to the plant, and from the plant to the animal. (Applause.)

These are some of the points, gentlemen, by relating which I wish to interest you; which demonstrate the overruling presence of One mind, directing practical operations to the same end. If there was not the same spirit and intellect pervading in the nature of the soil, the plants and the animals, there would be some confusion; but as they do exist, there is manifested the presence of One mind and of one principle, directing the whole cycle of animal and vegetable life, as there is to be seen in all the cycles and motions of the planetary bodies. (Loud applause.) In wishing to teach those under you the elementary principle of agricultural chemistry, I don't wish you to leave out of view the beautiful and powerful evidence which it affords of the existence of a deity who is present at all times, and regulates in his infinite wisdom all our affairs and intercourse. I therefore concur entirely in the remarks of Mr. Pyper, that moral training is above all things necessary for the young. Moral training comes first, intellectual next, and practical last of all; but yet all are here combined, for by this practical knowledge you can give the young mind a new view of natural theology. It is not merely chemistry or physiology, but this science seems to be one of the most beautiful pictures of natural theology. (Applause.) I might tell you there is a great deal of poetry in the sketch I have presented to you. The whole planetary system in dead masses float in space, and the dead earth forms the subject which geologists contemplate; but on the surface of this dead earth you have a soil, a vegetable and an animal life, subject to changes which must interest and concern every inquirer. Suppose the

soil contained no seed—that no vegetables grew, and no animals existed, still no doubt the other parts of the creation would go on; and this subject of ours is just one idea, an episode, as it were, in connection with the planetary system. And this little episode in the mighty poem of nature, presents to us the Divine bounty, goodness, wisdom, forethought, benevolence and the exalted intelligence of divine mind. How beautiful it is indeed! What an incontestible manifestation of the existence of the Deity is to be found in this episode, planted on our own globe! I have no doubt, gentlemen, that in imparting this branch of knowledge to those under you, you will enjoy an agreeable and entertaining study yourselves. I came among you an entire stranger, and therefore I have not been able to speak with the freedom and ease which, perhaps, I otherwise would have done; but I hope the kindness you have shown to me, and the attention you have paid to my explanations, will, in some measure at least, have made up for my deficiency. If you do me the honor to ask me again before you, I trust I shall be able to address you in a better manner than I have been enabled on this occasion to do.

The learned Professor resumed his seat amidst great applause.

Mr. Knox, of St. Ninians, expressed his great delight at the lucid manner in which Mr. Johnston had treated the subject, and the high gratification which he, in common with the other schoolmasters, felt at being honored with an address from one so eminently fitted for the task. He moved that the thanks of the meeting be voted to the Professor, which was unanimously agreed to.

The Chairman having shortly conveyed the thanks of the meeting, the learned Professor withdrew.

A Maryland Farm.

From the Albany Cultivator.

Yesterday I returned from a visit to GEORGE PATTERSON, Esq., who resides at "Springfield," twenty-two miles west of this, in Carrol county. He is a wealthy gentleman, and is extensively known for his fine stock and enterprising character. His farm contains 1,735 acres, about 1,200 under cultivation, and 500 in woodland. It is rolling land, and well watered—a branch of the Petapsco running through it, supplies water for a grist mill, on the farm, where all the grain raised on the farm is ground for the family and stock. The woodland is admirably located to shelter the many fields from the northwest winds, and presented a beautiful and diversified landscape. The timber was formerly oak, but as it is removed is supplanted by a spontaneous growth of hickory and chestnut, principally the latter. Mr. Patterson has cut out much of the old timber to burn lime, and also with a view to get rid of it to admit the young growth of chestnut.

When Mr. P. took possession of this farm, twenty years since, the land was poor, much of it *very* poor, and barren of vegetation, except *briars*, with scarcely any buildings. Since then he has put upwards of one hundred and sixty thousand bushels of lime on the land, and erected fifty buildings of various kinds, all permanently and neatly built, and now all yellow washed, presenting in contrast with the green fields and woods, a picturesque appearance. His plan is, whenever a field is brought into cultivation, and made to produce clover for mowing, to erect as many barracks as will hold the hay. These barracks or barns, are made of frame, some 20 by 30 feet square, 12 or 14 high, weather-boarded, and covered with cypress shingles.

Mr. Patterson commences on the poor worn-out land by spreading two hundred bushels of lime per acre (measured at the kiln unslaked,) on the surface, and lets it remain two or three years, then breaks it up and puts whatever dung he can muster, and plants it in corn. The following is his system of rotation:—First year, corn; second year, oats, rye or wheat, and clover sowed in the spring; third year, clover, first year mowed, second crop left on the ground; fourth year, clover either left on the ground or moderately grazed; fifth year, wheat, timothy sowed with the wheat; sixth year, timothy mowed; seventh year, timothy mowed; eighth year, grazed; ninth year, grazed and top-dressed the last four years. Top-dressing he prefers to plowing in the manure of any kind. Lime, he thinks, acts slowly, and does not show much the first year or two, and should be always applied to *grass*, and not on fallow. Much of this land is now in a high state of cultivation, producing 20 to 30 bushels wheat, 60 to 80 bushels corn, and two to three tons hay per acre. The contrast between this farm and some of the adjoining land is wonderful! The one green and luxuriant in crops, the other barren and devoid of vegetation, having no green thing except a few low running briars.

This land was also very stony. With the stones Mr. P. has turnpiked several roads across his farm, which enables him to haul wood, lime, and manure in wet weather. He has also applied a portion of these stones to making drains. He makes drains by cutting a ditch four feet deep, and filling two feet with fine broken stones. Swamps and swails heretofore useless, are now made dry, and are among the most productive parts of his land. The fences are in prime order—the few worm fences that he has are eleven rails high, staked and ridered, and six feet worm. The greater part are post and post and rails—upwards of ten thousand pannel—posts of mountain locust. A few chestnut posts he has been compelled to use, and these he protects from decay by filling round with stones, which drain the water rapidly off.

His barns, where the greater part of the cattle and hogs are fed in the winter, are situated on two opposite knolls, and drains are so arranged as to convey the wash from both to permanent meadows adjoining.

His stock is all of the most approved kind, and pure in blood. Of horses, there are several full blood mares of high pedigree and beauty. "Mary Randolph," a superb mare of rare good points, a gray, has a filly one year old, the handsomest creature I ever saw. He has in all some twenty-five or thirty fine horses of various ages. At present he is about crossing these mares with a large, well-formed horse, a cross of the Canadian—similar to the Morgan horse—with the view of increasing the size more suitable for carriage or draft horses. His herd of Devon cattle, about sixty in number, are a rare lot. I had heard of the Devon cattle and seen the prints representing them, but I had *no idea* of their beauty. The prints, or some of them, are *caricatures*, at least of Mr. Patterson's best cattle. His bull, "Eclipse," imported two or three years since, now five years old, is a perfect gem, the best bull of *any* stock, not excepting my old favorites, the Durham, that I have ever seen. The cows have fine shaped and well developed udders, and must be good milkers. Mr. Patterson says they give rich milk, and a good deal of it. He has bred his stock with that object, and selected the best milking families. They have size enough—the bull would weigh 1000 lbs. net beef—the cows are also large enough. They have fine shaped yellow noses, with a ring of the same round the eye—all uniform as so many peas. What will you think if I tell you that this will become the favorite stock before many years? The beef, you know, is celebrated for its fine quality, being so evenly mixed, fat and lean, instead of laying the fat on the surface.

Here I also saw upwards of seventy Berkshire store hogs—*hog fat*, in the clover field—and as many sucking pigs intended for next year. The sows are allowed but one litter each year, and they all have pigs in May. Mr. P. has a fine flock of sheep, some full blood Downs from the flocks of Mr. Rotch, N. Y., and Cope, of Pennsylvania.

Everything is done here in the best manner, and all the stock is of the *best*, without regard to price. The whole establishment is well worth one hundred thousand dollars. I have not done credit in the description. Mr. Patterson manages the farm himself—has no white man on the place but himself, and is a pattern in industry and frugality, even to Pennsylvania farmers. His neighbors are beginning to follow his example in the use of lime. A few years hence will have completed Mr. Patterson's plans of improvement, and then he will have the best farm in Maryland. ISAAC DILLON.

Eutaw House, Baltimore, May 20, 1845.

A Virginia Farm.

An agreeable correspondent of the Easton (Pa.) Whig, in the course of a recent tour to the valley of the Shenandoah, gives the following account of the fine residence and farm of a Virginia planter:

VIRGINIA FARMING.—Col. Tulley, who is admitted to be one of the best farmers in northern Virginia, has about 1200 acres in his plantation, of which about 900 are under cultivation, and which is wholly surrounded by a solid limestone fence six miles in length, and varying from 4 to 6 feet in height. He harvests this season 500 acres of wheat, which, notwithstanding the severe drought, he expects will yield him about 12,000 bushels. One is struck in looking over his fields to see how free all are from other grain and weeds. I asked him how it was that in a field of 100 acres of most excellent wheat not a spear of rye was visible. He said it was owing to the great care he took in cleaning his seed wheat. That if twice cleaning did not suffice he had it cleaned again and again until it was free from improper seeds. The editor of "The Valley Farmer" thus describes in a late editorial, the process of cultivation pursued by Col. Tulley:

"In the cultivation of his farm, Col. T. pursues what is call the 'five years' shift system,' and is as follows: he takes a field two years in clover, and turns over the sod in the month of August or early in September. From the 5th to the 15th of October, he sows a bushel and a half to the acre, and harrows it in. After the wheat is cut the field lies and becomes covered with a thick and strong growth of ragweed. In the following spring he turns up with a plow, and plants to corn before the middle of April. The corn is planted four feet apart each way, and eight or ten kernels to the hill. The cultivation is principally done with a plow, beginning as soon as the corn is fairly up, and plowing it both ways about four times in a season. At the second plowing the hoe follows, and the corn is thinned to two stocks in the hill. The hoe is seldom used but once, and the corn is hilled no more than the plow will do it. When the corn is so ripe that it will mature in the stock it is cut, and the land put into wheat. Sometimes he sows on the seed and plows it in; sometimes he first plows and then sows and harrows in the seed, being governed by the ground. After the wheat is sown the field is seeded in clover. After the wheat is harvested nothing is permitted to go upon the ground to disturb the young clover. The field then lies two years in clover, when wheat again follows. In the spring of each year, half a bushel to an acre of plaster is sown on the clover, and heavy crops of grass are in this way secured. In this course of farming he once raised from two acres of land 80 bushels of wheat; from a field of sixty acres, he averaged more than 30½ bushels to the acre, and from a field of thirty acres, 65 bushels shelt corn to the acre. He considers the clover and the plaster as the principal means of improving the soil; yet he is very careful to allow no manure to be wasted. On the contrary, he makes large quantities of it annually, which he applies to the highest parts of his fields, turning it under with the plow, which he prefers to using it as a top-dressing."

The harvest had commenced the day before we arrived, and it was a pleasant sight to look upon. Six or eight cradlers went ahead. They were followed by as many rakers, they by as many binders, while another group finished all

up. Besides this crop the Colonel has about 200 acres in corn and other summer crops in proportion. His sheep and cattle are of the best breeds, and in his herd are several buffalo cows.

THE PARK.—Over 20 fallow deer and a number of elk sport in his park. The early dawn is ushered in by the sweet carrolling of feathered songsters that here have no dread of man, for no gun is allowed to be shot upon the premises. The consequence is, that the birds make their home within the reach of the very windows, and thus sweet dreams are made still sweeter by the delightful music that accompanies them, and which, mingling with the bright visions of fancy as you be half sleeping, half waking, make you almost wonder as you open your eyes, whether you are not in the region so glowingly described by the Eastern fabulists. In the woods too, the squirrel chirps in the tree above you and gambols from bough to bough to attract attention, not knowing man to be his foe. Another great advantage of this benificent rule is, that the trees and plants in the neighborhood are preserved uninjured by those destructive insects that are doing so much evil to flowers, fruit and grain throughout our land.

THE GARDEN.—Adjacent to the pleasure grounds the Colonel has his fruit and kitchen garden, containing about three acres, surrounded by a high brick and stone wall, and filled with the finest kind of fruit and vegetables. In it are found over a dozen varieties of the strawberry, the choicest raspberry and other bearing bushes. A spacious garden-house gives great convenience in the cultivation of the ground and gathering in and preservation of its products. The basement is fitted to store away the winter vegetables. The first floor holds and keeps from injury from weather the garden tools and implements, while above is a capacious and well arranged pigeon-house. But although much attention, as is seen, has been given to the useful, the ornamental which tends to soften and minister to the kindlier feelings receives also the care of the Colonel and his fascinating lady.

THE GREEN-HOUSE.—Besides the beautiful flowers that line the many walks of the pleasure grounds and are interspersed throughout them, a fine green-house evinces the great taste for the beautiful that pervades the owner. In relation to it the editor of the Valley Farmer thus writes:

"In the green-house we noticed a large collection of exotics, the fragrance of which, when the folding doors were thrown open, emitted an odor through the rooms that reminded us of those strange romantic tales which lovers descant so much about, and which nine-tenths of them never realize even in their dreamy imaginations, Col. Tulley showed us many rare specimens of the rose, honey suckle, the magnolia, the Rose of Sharon and the Lilly of the Valley, so beautifully mentioned in Scripture, and the Bullrush of the Nile, such as formed the ark of the infant Moses. There we also found the Lemon and the Orange tree blossoming and bending 'neath the weight of their luxuriant fruit. There are many more rare plants which we should like to take notice of, but as we must bring our remarks to a close on this subject we would merely mention in this place, that the most beautiful flower blooming in this vast collection, is the smiling, laughter-loving native called '*mine hostess.*' "

We observed in the finest specimen of the wax plant we have ever seen, a perfect curiosity covering half of one of the sides of the green-house, filled with clusters of those delicate flowers.

An Alabama Plantation.

By GOV. HILL, *Editor of the Farmer's Monthly Visitor.*

The county of Montgomery, of which the busy town of the same name is the capital, is said to be the most wealthy agricultural district of the State: at this place several citizens of New Hampshire have located and resided within the last twenty years. In a somewhat hurried journey home from New Orleans, the editor of the Visitor was induced to stay over at Montgomery one day, by old friends who solicited a longer tarry.

Mr. Seth Robinson, an old trade acquaintance of this town, who has resided through all the vicissitudes of prosperity and depression for several years at Montgomery, and is now settled down in a prosperous business, desiring to show us the specimen of an Alabama farmer, took us an afternoon ride seven miles out of the city. Passing on the great road from Montgomery eastward toward Georgia, by several beautiful plantations, and many extensive enclosures devoted alternately to a forest growth and cultivated fields for cotton, corn and the other cereal grains, he brought us to the premises of Col. Green Wood, a planter who emigrated here several years ago from the State of Georgia. This was the 4th of April, and vegetation was then in the condition of what we might expect to be in New England on the 4th of July.

For nearly two miles before we reached his house, on both sides of the road, did we pass successive enclosures of his plantation, in which cotton or corn had been planted or grain had been sowed—all of it with as clean cultivation as a New England garden: the rows of cotton in a direct line to the distance of one hundred rods and half a mile, straight as an arrow, were traceable by the naked eye. The fences of this country, for which there has been abundant materials ready at hand, are of a kind which we in New England call the "Virginia fence." They are made of split rails of hard wood, and to that careful height of seven or eight feet, which would seem to be sufficient for shutting out the fleetest deer. The habit of careful farming is shown in Alabama by the safe fences surrounding each cultivated field. That part of the fence nearest the ground soonest decays; and we observed, as the older rails were crushed down at the bottom, their places were supplied by newly split rails at the top.

The mildness of the climate renders it unnecessary to pay that particular attention to the construction of houses, barns and sheds that we of the north must do from necessity. Little more is necessary there than to make a roof for the protection of cattle and crops; the negro residences are sometimes without floor of boards: a single outside boarding or clapboarding is deemed for them sufficient. Indeed, the rich owners themselves often occupy houses which would not be regarded as comfortable by the poorest tenant of the north. The habitation of Col. Wood, decorated with all the artificial embellishments of a flower garden and beautiful parterre on either front, was surrounded at no great distance with the numerous dwellings of the families, which do all the work upon his extensive plantation. The first noise that arrested our attention was the busy hum of the spinning wheel and the song of its operatives from the dwellings of the colored people. The enterprising owner of the premises was not at home himself; but meeting us at the door and inviting our entrance was his wife, a lady of plain dress and great sociability of manners, who at once made us at home in a warm day by the invitation to glasses of sweet ice-cooled buttermilk, and a walk into an extensive garden, clothed in all the rich beauties of early vegetation. Here we found—and the reader will mark the day to the 4th of April—rich head lettuce fully grown and growing in the open air, ripe strawberries and full grown peas: as an evidence of the early season, Mrs. Wood plucked from the tree a full sized fig which then only remained to be ripened. Fronting this garden of several acres, was another larger enclosure of flourishing peach, apple and other fruit trees which had then gone out of blossom.

The family residence of Col. Wood was a well-finished and elegant wooden house of a single story. There were wide halls with entrances on the four sides, so that in whatever direction might be the wind, the house had the advantage of airing: these halls embraced nearly half of the whole area. Separate on each corner were large and ample parlors or sitting rooms, and one or more suits of bed rooms. The height of the story and the rooms was ten to twelve feet. This house was constructed for comfort in warm rather than cold weather: the weather in that part of Alabama is never cold, and seldom only cool.

The extent of farming in Alabama may be conjectured from the fact that Col. Wood has one thousand acres annually under the plow. Good calculations make the work there comparatively easy, because the milder climate admits of work in the preparation for crops nearly the whole year round. All the heavy manual labor in the fields is the work of horses and mules. The virgin soil in that State is so rich that the planters hitherto have paid little attention to manures. The facilities for making barn and stable manure are not in the cotton region as great as at the North. Col. Wood found means in various ways to make a large amount of manure in the last season; he disposed upon a portion of his plow land one thousand mule or horse cart loads, for which purpose he employed four carts with the drivers during the last winter. His manure was taken from the stables and from the cattle, sheep and hog yards.

Of his cultivated lands five hundred acres are devoted to cotton, and an equal amount to corn, wheat, rye, oats, &c. The one-half of the farm furnishes more than the whole amount of meat and bread for the laborers, by whom also the clothing is manufactured from the cotton and wool grown upon the premises. The principal part, if not the whole of the cotton crop, must be regarded as clear profits. A force of thirty to forty mules or horses with their drivers, kept up during the greater part of the year, is sufficient for the cultivation of these many acres.

A more happy set of laborers can hardly be conceived than the slaves upon the plantation of Col. Wood. The daily task of those engaged in the out-door work is easy; and they have much time every week which they call their own, with opportunities to cultivate their little garden plot, to raise and feed poultry, with other extra privileges. They are all well fed and clothed in the abundance which the plantation produces, with little of the concern which poor people of other countries experience. Upon the faces of the colored people which we saw about the premises health and contentment were depicted: the women chanted with their voices of song and music correspondent to the movements of carding and the buzz of the spinning wheel.

Col. Wood had two overseers, white men, to superintend the plantation concerns. One of these in the short time of our tarry, showed us about his premises, which would do credit to the best New England farmer. As the better method of furnishing abundant meat at all times, he has five hundred hogs of the different sizes. Better than the hogs which abound in the forests of the West and the South, appeared the animals of Col. Wood: he had not only been at the pains to introduce an improved and mainly of the Berkshire breed, but his hogs were decidedly more fat than we had seen elsewhere. They ranged in an open forest ground and pasture of many acres; and in addition to this only usual method of keeping and feeding hogs in that country, they were daily fed with corn in the ear scattered over the ground in which they rooted and made manure.

No hay is cut in Alabama: a general substitute in feeding horses, mules and cattle is the corn shucks or husks, being the leafy part which is stripped from the principal blade and done up in bundles. The straw of wheat with other kinds of grain and the grain itself is also fed out to the horses and cattle. The cows, in most instances, range the woods in search of food, and through the forests of Alabama and Georgia where we passed, seemed to be but skeletons, like the lean kine of Pharaoh. Col. W. had a fine drove of the milch kine, large, fat and sleek, and a notable bull which the overseer

informed us was obtained from Col. Jaques, of Charlestown, Mass. A flock of over a hundred first rate sheep, a mixture of the Leicester with the native breed, were kept mainly for the wool necessary for the family clothing.

On the whole, the view of such a splendid plantation as that of Col. Wood's, a thousand acres under the plow, yielding, on the lowest calculation, a clear profit of ten dollars to the acre—the business under overseers who make the different gangs of cheerful workers operate like the machinery of a clock; a portion of the grounds every year improved by the generous use of manures; the crops all gathered and saved in due season, as they are grown, almost without the apparent care of the owner; the surplus annually sold to furnish any desirable amount of funds for any desirable purpose:—who would not think the evil of slavery such as exists upon this plantation even tolerable, and who would not envy the condition of an independent Alabama farmer like Colonel Green Wood?

Barn Yards.

The following "*Remarks on the Construction and Management of Cattle Yards,*" are from the pen of the late Judge Buel, of Albany:

Vegetables, like animals, cannot thrive or subsist without food; and upon the quantity and quality of this depends the health and vigor of the vegetable as well as of the animal. Both subsist upon animal and vegetable matter, both may be surfeited with excess—both may be injured by food not adapted to their habits, their appetite or their digestive powers. A hog will receive no injury, but great benefit from free access to a heap of corn or wheat, where a horse or cow will be apt to destroy themselves by excess. The goat will thrive upon the boughs and bark of trees, while the hog would starve. The powerful, robust maize will repay, in the increase of its grain, for a heavy dressing of strong dung, for which the more delicate wheat will requite you with very little but straw. The potatoe feeds ravenously, and grows luxuriantly upon the coarsest litter, while many of the more tender exotics will thrive only on food upon which fermentation has exhausted its powers. But here the analogy stops: for while the food of the one is consumed in a sound, healthy, and generally solid state, the food of the other before it becomes aliment, must undergo the process of putrefaction or decomposition, and be reduced to a liquid or æriform state.

I have gone into the analogy between animals and vegetables thus far, to impress upon the minds of our farmers the importance of saving and of applying the food of their vegetables with the same care and economy that they do the food of their animals. How scrupulously careful is the good husbandman of the produce of his farm destined to nourish and fatten his animals; and yet how often careless of the food which can alone nourish and mature his plants: while his fields are gleaned and his grain, hay and roots carefully housed, and economically dispensed to his animals, the food of his vegetables is suffered to waste on every part of his farm. Stercoraries we have none. The urine of the stock, which constitutes a moiety of the manure of animals, is all lost. The slovenly and wasteful practice of feeding at stacks in the fields where the sole of the grass is broken, the fodder wasted, and the dung of little effect, is still pursued. And finally, the little manure which does accumulate in the yards, is suffered to lie till it has lost full half of its fertilizing properties, or rotted the sills of the barn; when it is injudiciously applied, or the barn moved to get clear of the nuisance. Again: none but a slothful farmer will permit the flocks of his neighbors to rob his own of their food; yet he often sees, but with feeble efforts to prevent it, his plants smothered by pestiferous weeds and plundered of the food which is essential to their health and vigor. *A weed consumes as much food as a useful plant.* This, to be sure, is the dark side of the picture, yet the original may be found in every town, and in almost every neighborhood.

Is it surprising that under such management our arable grounds should grow poor, and refuse to labor its accustomed reward? Can it be considered strange that those who thus neglect to feed their plants should feel the evil of light purses as well as of light crops? Constant draining or evaporation, without returning anything would in time exhaust the ocean of its waters. A constant cropping of the soil without returning anything to it, will in like manner exhaust it of its vegetable food and gradually induce sterility. Neither sand, clay, lime or magnesia, which are the elements of all soils, nor any combination of part or all of them, is alone capable of producing healthy plants. It is the animal and vegetable matter accumulated upon its bosom or which art deposits there, with the auxiliary aid of these materials diffused in the atmosphere, that enables the earth to teem with vegetable life and yield its tribute to man and beast.

I will now suggest a cheap and practicable mode of *providing food for vegetables*, commensurate to the means of every farmer of ordinary enterprize; and that my suggestions may not be deemed theoretical, I will add, that I "practice what I preach."

The cattle yard should be located on the south side of and adjoining the barn. Sheds, substantial stone walls, or close board fences should be erected at least on the east and west sides, to shelter the cattle from cold winds and storms; the size proportioned to the stock to be kept in it. Excavate the centre in a concave form, placing the earth removed upon the edges or lowest sides, leaving the borders ten or twelve feet broad, of a horizontal level, to feed the stock upon, and from two to five feet higher than the centre. This may be done with a plow and scraper, or shovel and hand-barrow, after the ground is broken up with the plow. I used the former and was employed a day and a half, with two hands and a team, in fitting two to my mind. When the soil is not sufficiently compact to hold water the bottom should be bedded with six or eight inches of clay well beat down and covered with gravel or sand. This last labor is seldom required except where the ground is very porous. My yards are constructed on a small loam, resting on a clay subsoil. Here should be annually deposited as they can be conveniently collected, the weeds, coarse grass and brakes of the farm; and also the pumpkin vines and potatoe tops. The quantity of these upon a farm is very great, and are collected and brought to the yard with little trouble by the teams returning from the fields. And here also should be fed out or strewed as litter, the hay, stalks and husks of Indian corn, pea and bean haulm, and the straw of grain not wanted in stables. To still farther augment the mass, leached ashes and swamp earth may be added to advantage. These materials will absorb the liquid of the yard, and, becoming incorporated with the excrementitious matter, double or treble the ordinary quantity of manure. During the continuance of frost the excavation gives no inconvenience, and when the weather is soft the borders afford ample room for the cattle. In this way the urine is saved and the waste incident to rains, &c., prevented. The cattle should be kept constantly yarded in winter, except when let out to water, and the yard frequently replenished with dry litter. Upon this plan from ten to twelve loads of unfermented manure may be obtained every spring for each animal; and if the stable manure is spread over the yard, the quality of the dung will be improved and the quantity proportionably increased. Any excess of liquid that may remain after the dung is removed in the spring can be profitably applied to grass, grain or garden crops. It is used extensively in Flanders and in other parts of Europe.

Having explained my method of procuring and preserving the food of vegetables, I will proceed to state my practice in feeding or applying it. It is given every spring to such hoed crops as will do well upon coarse food, (my vegetable hogs and goats.) These are corn, potatoes, ruta baga, beans and cabbages. These consume the coarser particles of the manure, which would have been lost during the summer in the yard, while the plow, harrow and hoe eradicate the weeds which spring from the seeds it scatters. The finer parts of the food are preserved in the soil to nourish the small grains which follow. The dung is spread upon the land as evenly as possible, and immediately turned under with the plow. It is thereby better distributed for the next crop, and becomes intimately mixed and incorporated with the soil by subsequent tillage. Thus, upon the data which I feel warranted in assuming, a farmer who keeps twenty horses and neat cattle will obtain from his yards and stables, every spring, two hundred loads of manure, besides what is made in summer, and the product of his hogsty. With this he may manure annually ten or twelve acres of corn, potatoes, &c., and manure it well. And if a proper rotation of crops is adopted he will be able to keep in good heart, and progressively to improve, sixty acres of tillage land, so that each field shall be manured once every four or five years on the return of the corn and potatoe crop.

Grasses for the South.

From the Albany Cultivator.

Your correspondents frequently inquire respecting the grasses suitable for the South. If each would communicate what he had observed it would be a sufficient answer to such inquiries, and might prove the most important benefit to the agriculture of the South. During this winter I have seen bundles of *Northern hay* brought to the stables of my neighbor, which had paid for carriage many hundred miles round the capes of Florida, through the Gulf of Mexico, and five hundred miles (by the course of the river) into the interior. This is a *standing reproach* to the agriculture of the South.

Lucerne.—This is found to grow well here. Sow it in drills in the early part of the fall, 24 to 27 inches apart; it flourishes, yields four to five cuttings in the course of the year; and on soil which would bring 20 bushels of corn to the acre, grows a foot and a half high. This season, some was cut on the 12th of March for soiling, and was then from a foot to knee high. The most of it has been cut twice over since the first cutting, to this day, May 13. Cattle and horses eat it greedily; a cow fed on it chiefly is yielding at this time between five and six gallons of milk daily; when as yet there is no grass in the woods or on the common sufficient to change the poverty-stricken appearance of the cattle in "the range." I have made no hay from it, but have no doubt it will make good hay.

Guinea Grass.—The root is similar to that of the cane or reed, and is perennial. The stem and blade are like those of the Egyptian Millet. On rich soil it is very luxuriant, yielding many cuttings in the course of the year. It is good for soiling—horses and cattle eat it readily, and if cut when in flower, it makes a hay most abundantly which cattle eat greedily in winter. Horses do not seem to like the hay. It is most readily propagated by the root. A small root two inches long, with one or more joints to it, will vegetate, and, if the ground is made loose by plowing once or twice during the season after planting, roots placed in checks of four feet will take *complete possession of the soil the first season*; so that the next spring it will start up evenly over the soil anywhere. Hogs root after them with great eagerness, and as the tendency of this plant is to fill the grouud with roots in so thick a mat that the grass does not grow tall in consequence, the idea suggests itself of pasturing cattle on this grass in the spring and summer, and giving the hogs the benefit of the roots in the winter. They cannot destroy it; the smallest fibre left in the ground will grow. It might be a great pest in a garden; but if

land is to be used for stock it will take and maintain entire possession to the exclusion of any competitor which we have in middle Alabama.

Clover and Herd's Grass — I have now a beautiful lot of these grasses in conjunction on high land, the whole about knee high, and the clover in flower. Mr. Kirby, one of my neighbors, cut the wood from a piece of low, pipe clay, crawfish land last winter, and when the brush, &c., lying on the ground, had become sufficiently dry, he set fire to it and burnt it all off, thus giving it a top dressing of ashes. He then sowed Herd's Grass on the top of the ground, without plow, harrow or anything of the kind. He now has a most rich and beautiful crop of this grass growing. If desired, your readers may obtain further particulars of this crop.

Leersia Orizoides, (rice grass.)—This plant so much resembles *rice* that only a practised eye can distinguish them. The negroes on the rice plantations in Carolina call it "*the rice's cousin.*" It will grow wherever rice will—*in the water* or in any damp situation. It is found wild in all the Southern country; grows tall, seeds in a panacle not unlike a head of oats, and will yield two crops a year of *choice hay.* Roots perennial. B. M.

Tuskaloosa, Ala., May 13, 1845.

Foolish Planters.

From the Augusta Constitutionalist.

Permit me, Mr. Editor, through the medium of your columns, to notice what I consider a very silly and most pernicious proceeding on the part of our planting friends, to which my attention has again been drawn, from noticing the usual annual articles:

"The first new cotton in market from the plantation of Mr. ——, —— county, sold for — cents!!!"

It is not my intention of enlightening the world as to the "*modus operandi*" at times resorted to, of achieving this most astonishing feat; whether the bolls were well sunned to cause them to open, whether old cotton was slightly mixed to make up quantity, what amount of labor was bestowed upon the laudable and useful undertaking, how long it remained packed before being opened to prevent its rotting, nor the extent of gratification enjoyed by the enterprising planter. These are but trifling and local matters.

I wish to deal with the practical effect of this folly. It certainly cannot escape the notice of any man of intelligence, that the cotton trade has a host of people engaged in it, whose every thought and aim is to depress prices. The banker, holding the available and active wealth of the country—for he gets the better bill the lower the price is—and the manufacturing interests, for the cheaper the cotton the greater the profit—and the agent purchasing, for the lower the price the more the orders can be executed—and a host of dependants are alive to everything relating to this trade, sparing no cost or labor in procuring every possible information, as to the amount planted, state of the seasons, &c. &c.

One of the reliable modes of calculation by them, is from the time the first blossom is observed, to the first killing frost—again, from the first new cotton being in market, to the first killing frost—this is relied upon for length of season—if an average period the crop is considered an average one—if an *unusual* period, a large one.

Now, instead of permitting nature to take its course, gathering with care the harvest when it is ripe, we (for a vain boast) must anticipate this event, and arm our enemies with an irresistible argument to rob us of our labor.

The fact of the early receipt, is at once heralded in Augusta, or the market it is brought to. A full price must be given the industrious owner of the one or two bales hauled to market, perhaps 75 miles, over a sandy road, by a hard-worked and poor team, with the thermometer at 95 to 100 degrees in the shade: some merchant must have the first new cotton in New York, for he may then see his name and his friend's in the newspapers of that city! Off it goes, and so on till it finds its way to Liverpool, a month earlier than the represented state of the growing crop led parties to anticipate. Calculations from this *fact* are at once made, the talk of late spring and dry season—is put down "a usual humbug," and the market of Liverpool, governing all other markets, becomes at once languid and depressed.

That this has been, and is likely to be the case, I will only state what took place a few years ago: A planter in South Carolina sent in July, two bales of cotton to the Augusta market; they were at once sold, sent per rail road to Charleston, and by steam packet to New York, there they were purchased by the agent of a merchant spinner, shipped per "Great Western," and on the 16th day of August landed in Liverpool.

The anticipated effect of this shrewd agent was at once realized. The cotton market, (there in a good state,) paused, reeled and tumbled—in three weeks prices went down 2 cents a pound, and continued at that depression for four months, causing a loss to American holders of cotton estimated at one and a half millions of dollars, and perhaps as much more to planters upon their new crop. But what availed all this—the planter had his name in the papers—glory enough for one day.

Let us hope, Mr. Editor, for more intelligence in future; but if persisted in, I must call upon the trade of Augusta unanimously to vote a leather medal for next year.

A PLANTER'S FRIEND.

Getting Poor on rich Land, and Rich on poor Land.

A close observer of men and things told us the following little history, which we hope will plow very deeply into the attention of all who plow very shallow in their soils:

Two brothers settled together in —— county. One of them on a cold, ugly, clay soil, covered with black-jack oak, not one of which was large enough to make a half dozen rails. This man would never drive any but large, powerful, Conostoga horses, some seventeen hands high. He always put three horses to a large plow, and plunged it in some ten inches deep. This deep plowing he invariably practiced and cultivated thoroughly afterwards. He raised his seventy bushels of corn to the acre.

This man had a brother about six miles off, settled on a rich White river bottom-land farm—and while a black-jack clay soil yielded seventy bushels to the acre, this fine bottom land would not average fifty. One brother was steadily growing rich on poor land, and the other steadily growing poor on rich land.

One day the bottom-land brother came down to see the black-jack oak farmer, and they began to talk about their crops and farms as farmers are very apt to do.

"How is it," said the first, "that you manage on this poor soil to beat me in crops?"

The reply was, "*I* WORK *my land.*"

That was it, exactly. Some men have such rich land that they won't *work* it, and they never get a step beyond where they began. They rely on the *soil*, and not on labor or skill, or care. *Some men expect their* LANDS *to work, and some men expect to* WORK THEIR LAND—and that is just the difference between a good and a bad farmer.

When we had written thus far, and read it to our informant, he said, three years ago I travelled again through that section, and the only good farm I saw was this very one of which you have just written. All the others were desolate, fences down, cabins abandoned, the settlers discouraged and moving off. I thought I saw the same old stable door, hanging by one hinge, that used to disgust me ten years before; and I saw no change except for the worse in the whole county, with the single exception of this one farm.—*Ind. Farmer and Gardener.*

Blading and Topping Corn.

No one performs these operations for the benefit of the ear, but to obtain fodder; and it is then justified on the ground that the corn is not harmed by it. The sap drawn from the root does not flow strait up into the ear and kernel, but into the *leaves* or blades. The carbonic acid of the crude sap is decomposed, oxygen is given off and carbon remains in the form of starch, sugar, gum, &c. &c., according to the nature of the plant. When sap has by exposure to light undergone this change, it is said to be *elaborated.*

It is only now that the sap, passing from the upper side of the leaf to a set of vessels in the under side, is reconveyed to the stem, begins to descend, and is distributed to various parts of the plant, affording nourishment to all. But when the fruit of every plant is maturing it draws to itself a large part of the prepared sap, which, when it has entered the kerne, is still farther elaborated and made to produce the peculiar qualities of the fruit, whether corn or wheat, apple or pear. It is plain, from this explanation, that a plant stripped of its leaves is like a chemist robbed of his laboratory, or like a man without lungs.

If corn is needed for fodder, let it be cut close to the ground, when the corn has glazed. The grain will go on ripening, and be as heavy and as good as if left to stand, and the stalk will afford excellent food for cattle. Sheep are fond of corn thus cured, and will winter very well upon it. In husking out the corn, the husk should be left on the stalk for fodder.—*Indiana Farmer.*

Let Farmers Communicate—Improvement.

MR. EDITOR:—Farmers should be communicative of their agricultural knowledge. They should be as willing to give information to a brother, as they are particularly anxious to receive the like at the hands of others. They should inquire, search, experiment, and endeavor to advance the general agricultural interest by every possible means and measure. What should be thought of a farmer, who, having the necessary right kind of knowledge to double his own harvest—which very properly and prudently he does—yet, will not impart one iota of the secret to his neighbor, that he may do the same? Such there may be, but assuredly he is unworthy that appellation "brother farmer."

The real genuine farmer is wholly given to the work. Next to his duties due high Heaven, it is his all absorbing topic. He loves to *hear* about farming; he loves to *talk* about farming; the *study* of farming is to his taste. He thinks, reads, composes, reflects and stores his mind with treasures of knowledge applicable to the profession. All other knowledge is acquired only to subserve the interests of this. In this way, the farmer *must* and *will* rise. It is as necessary to the prosperity, the onward and upward march of the farmer, that he study and apply the stores of knowledge, to the work of his hands as in any profession or business whatever. Let him patiently and perseveringly do it then, and look up and live.

Farmers should take courage under a view of the immense change in his favor there has been wrought within the last thirty years. Thirty years ago! Where then was the flood of agricultural reading now sent forth to enlighten the land and make glad the hearts of the hearty yeomanry! And what was the state of agricultural science? Did the farmer then suppose science had any thing to do with the practice of husbandry! What too was then the state of agricultural implements? What for a plow did he turn the stubborn glebe with? and what for a cultivator and hoe did he essay to till the half broken field with? Indeed, farmers can tell, for they know.

Farmers, under a sense of what has been done and is now being done for them, should look up, respect themselves, and adore that Providence that has so kindly undertaken to advance their general weal. Respectfully,

Butler's Vale, Dec. 1845. B. F. WILBUR.

Resuscitation of Worn-out Land.

Four years ago, two gentlemen of this city, (Baltimore,) bought each a ten acre lot, adjoining each other, on the road leading through the Canton property to Patapsco neck. At the time of the purchase, these lots were the very pictures of poverty personified, slightly covered with sedge-grass of a stunted growth. Some years previous we had seen them in corn, with stalks about the thickness of a man's thumb; as to ears, there were none---of nubbins even, the produce was scarcely worth gathering. The first spring after these lots came into the possession of their present owners, they each plowed his respective lot as deep as strong double horse teams and good plows could plow it, then put on thirty double horse cartloads to the acre, of compost formed of street dirt and stable manure; then cross-plowed the manure in some 4 inches deep, spread 100 bushels of soap-boilers' ashes to the acre, broadcast; harrowed and rolled their ground, listed it 4 feet by 2, and planted it in corn, putting a handful of plaster and ashes on each hill. The product was 86 bushels of good sound shelled corn to the acre.

The cultivation of the corn, after the first plowing, was with the cultivator and hoe, the object of the proprietors being to maintain a flat surface, with the view of seeding the lots down in grass. In August, after the corn had been laid by, the harrow was passed through the rows, and a peck of timothy seed and 8 lbs. of clover seed, sown upon each acre, which was harrowed in with a light harrow.

The grass seed took well, and has produced from two and a half to three tons of excellent hay to the acre last year and the year before. We saw these lots a few weeks since, and from their luxuriant appearance, we should judge that their yield the present year will be equal to that of the two preceding years.

To enable the uninitiated to understand what is meant by soap-boilers' ashes, we will remark that they are spent ashes, and generally contain about two-fifths of lime in their composition; so that he who uses them, both ashes and limes his land at one and the same time.

A great horror is generally entertained at buying worn-out lands; and, indeed, where means and plenty of money are not at hand to improve them, this horror is very justly entertained; for no amelioration can be produced until you restore to the soil the elements of fertility of which it may have been deprived by long continued and improvident culture---but where the soil has been *once good*, it is an easy matter, with the proper kind of manure and plenty of it, to restore its wonted fertility. That such is the case, the lots in question offer the strongest evidence. For, from a state of abject poverty, they were brought up, by a single manuring, to a state of the highest fertilization, and have now, for the third year thereafter, maintained it.

The facts presented by this instance of restoring lands, once good, after being impoverished by an improper course of culture, should not be without its *moral*, as they hold out inducements to the owners of such lands to exert themselves by all possible means, to accumulate manures and apply them to their exhausted fields, as there are none so poor but may be brought up by proper applications, in sufficient quantities, of vegetable, animal and mineral manures---and they point too, with unerring certainty, to the propriety of undertaking the improvement of no more land at a time than can be well improved. We are very certain that neither of these lots, unaided by manure, would have produced more than 15 bushels of corn to the acre, and yet we see these poverty-stricken soils brought up in a single season, to the capacity of yielding 86 bushels, being over five times that quantity, and continuing their fertility for four years in succession, with every prospect of a thorough restoration having been effected.

To Cook Tomatoes.—He that does not love tomatoes is an object of pity. Every art of cooking should be employed to inveigle the appetite of every man to love a vegetable so wholesome.

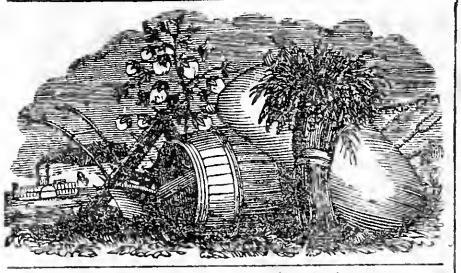
Peel a dozen ripe tomatoes and fry them in a little sweet butter, (which nine Hoosiers out of ten will understand to mean a little clean lard,) together with two or three sliced green peppers; sprinkle on a little salt, and finally slice up an onion or two, and let the whole cook thoroughly. This is the Spanish method of preparing them.

Another method, which, from a long experience we know will wear well, is as follows. The directions are for a mess of tomatoes amounting to about three pints when cooked:

Begin by parboiling two onions. While this is doing peel the tomatoes, which is easily done after hot water has been poured over them—cut them up and add the onions, also a teacupful and a half of bread crumbled fine, a table spoonful of salt, a heaping teaspoonful of black pepper, a lump of butter of the size of a turkey's egg, or about four table spoonfuls. Beat these thoroughly together and set them over a slow fire to stew. They should cook slowly and for a long time; never less than three hours, but the longer the better. About fifteen minutes before they are to be used beat up six eggs and stir them in, and put them on fresh coals and give them one grand boil up, stirring them all the time. When so cooked no directions will be needed how to eat them.

The art of cooking the tomato lies mostly in cooking them enough. They should be put to work the first thing after the breakfast things are out of the way, even if you do not dine till three.—*Indiana Farmer.*

The ignorant man is dead even while he walks upon the earth—though he is numbered with the living.



The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 10.....OCTOBER, 1845.

Wheat.

In the course of this month, those who intend to plant wheat will be getting their ground in order, and towards the end of the month they will be putting the seed in the ground. Very much of the success of the crop and of the quality of the grain will depend on the manner in which the ground shall be prepared for the reception of the seed, and on the proper selection and preparation of the seed itself. In the former particular—the preparation of the ground—the practice of Southern planters has been very especially careless: so much so, indeed, as to have occasioned the remark that if, in those States where wheat is a main crop, the ground were prepared and the seed sown in a manner as slovenly as by many Southern planters, nothing at all would be made. The great defect in our practice in preparing for this crop, as well as all others, consists in our shallow plowing. This is to be remedied by subsoiling, about which there has been so much said in the CULTIVATOR. Then, as to the soil itself, the defect, in most parts of the South, is the deficiency of lime and potash. Every wheat grower ought, by all means, to put on his wheat land, where this deficiency exists, at least ten bushels of lime, and the like quantity of ashes, to the acre. These both contain essential ingredients of both straw and grain, as has been repeatedly shown by analysis. And where they are liberally supplied to soils deficient in them, other things being properly attended to, there will be produced large heads of wheat filled with large, plump grains, and straw of strength sufficient to hold such heads up. If the lime and ashes cannot be applied when the wheat is sown, it will answer as well —some say better—to defer it till winter. When the land is poor, the American Farmer says, "the cheapest as well as the best manure that could be used would be Guano, in the proportion of 150 to 300 pounds to the acre, to be mixed with about ten times that quantity of mould, and one bushel of plaster. The whole to be mixed together, sown broadcast, and lightly harrowed in at the time of sowing the grain, or any time during the winter;" omitting the use of the harrow in the latter case, of course.

Where Guano cannot be had, the American Farmer recommends as a very excellent substitute, the following mixture:—"Take 2 bushels of ground bones, 2 bushels of ashes, 10 bushels of rich loam or mould, 1 bushel of plaster, 2 bushels of salt, and 20 gallons of urine; mix the whole together well; let the mass remain for a few days, when it will be fit to sow. The quantity here named is intended for an acre, and would, we have no doubt, tend to increase the yield thirty-three per cent. in the crop of wheat, besides greatly improving the succeeding crops of any rotation which might follow, and leaving the ground in a meliorated condition."

Where are we to get the bones? you ask. Yes, there is the difficulty in making use of this prescription. We in the South are not poor enough yet to begin to save bones, but we soon will be, going on as we do now. Let any one, however, think for a moment of the quantity of bones he might save on his plantation if he were to set about gathering up what are thrown out to bleach in the sun, or be consumed by the abominable race of sheep-stealing dogs with which the whole country is infested, and the difficulty will vanish. Besides, you have only to create a demand for ground bones, and the demand will be speedily supplied with the article from abroad. The field of Waterloo, for many years after that battle, supplied not only many of the wheat fields of England with bones for the improvement of the soil, but also many of the English millers with bones for the improvement of the weight of their flour, in the same way as some Northern millers are said to use Plaster of Paris to improve the weight of buckwheat flour for our Southern markets, producing, in this buckwheat case, results very surprising indeed, and profitable beyond anything that could be accomplished by the application of the same quantity of plaster to the soil where the buckwheat grew.

"To prevent smut,"—we quote from the American Farmer—"all seed wheat should be well washed in clean water, so that all the lighter grains and the seeds of weeds may be skimmed off. To insure this, the wheat should be put into a hogshead, in small quantities at a time; kept stirred, so that the impure grains and extraneous matters may be floated to the top. This process should be continued until all such are removed, and the water, which should be drawn off and replenished occasionally, ceases to be colored by the operation. After this has been effected, let a brine be made of salt or lye of ashes, sufficiently strong to bear an egg; cover the seed wheat with it and let it soak for twelve hours; then draw off the soak, spread the wheat on a floor, sprinkle slaked lime or ashes over it, and stir up the mass so as to coat each grain with the substance used. When this is done the wheat will be ready for sowing. No more wheat must be taken out of the soak than can be sown each day, and care should be taken to plow it in as sown, not more than about *three inches deep*. The *harrow* and *roller* should follow the plow. Seed thus prepared and put in, will, besides being exempt from smut, come up quicker, grow more rapidly, and, of consequence, obtain a much better series of roots before winter, than would such as may be sown without preparation, and therefore be better able to withstand the effects of frosts and thaws."

Sir John Sinclair recommends, to prevent smut, to run the grain very gently through a riddle into clean water, when not only the smut balls, but the imperfect grains and the seeds of weeds, will float, and may be skimmed off at pleasure. As a further means of preventing smut, he recommends steeping the seed in any one of the following preparations: 1. Pure cold water and lime. 2. Boiling water and lime. 3. Water impregnated with salt. 4. Urine pickle. 5. Lye of wood ashes. 6. A solution of arsenic. 7. A solution of blue vitriol.

Arthur Young sowed beds with wheat seed that was black with smut. The first bed sown with unwashed seed had 377 smutty kernels. A bed with seed washed in clean water had 325 bad kernels—washed in lime water, had 43 kernels; in lye of wood ashes, had 31; in arsenic and salt mixture, 28; steeped in lime water, four hours, had 2; in lye, four hours, had 3; in arsenic solution four hours, had one smutty kernel; steeped in lye 12 hours, had none; in lye 24 hours, none; in lime water 24 hours, none; in arsenic 24 hours, had five smutty grains.

Smut, then, can be gotten rid of. Everybody knows how to escape, to a great extent, the ravages of the fly. We wish the same could be said of rust, the only other serious malady wheat is liable to. On this subject, notwithstanding so much has been written, very little, we believe, is known that is really useful. Both the cause and cure are nearly as much involved in mystery as ever. Sir John Sinclair, in his *Code of Agriculture*, discusses the subject at length, and recommends as remedies that were most efficacious in his time:

1. Cultivating hardy sorts of wheat.
2. Early sowing.
3. Raising early varieties.
4. Thick sowing.
5. Changes of seed.
6. Consolidating the soil.
7. Using saline manures.
8. Improving the course of crops.
9. Extirpating all plants that are receptacles of rust.
10. Protecting wheat plants by other crops.

Mr. Colman's attention was directed to this subject, in New England, and after experiments carefully made, and extensive reading and observation, he came to the conclusion that, early sowing, from the best observation he had made of wheat crops that had come under his notice, from the united and decided opinion of the British wheat growers and from many American authorities, is to be strongly advised as a preventive of rust. This may do in New England, but in the Southern States early sowing exposes the crop to the ravages of the fly.

Of late, it has been confidently asserted that charcoal dust spread liberally over the ground is a sure preventive of rust. But here we want more light, and careful experiment alone can furnish it. Who will not be willing to undertake the experiments necessary to test not only this matter, but also many others connected with this crop?

"Now then, farmers"—to use the language of the Ohio Cultivator—"one and all, what will you do towards accomplishing this desirable object? It is vain for us to write or talk or travel amongst you, if you do not put forth the necessary efforts to carry into effect the measures that may be recommended, or to test by experiments the plans of improvement that may be suggested by the discoveries of science. Here then is work for you all! Some of you we know have already engaged in it, and are acting upon the numerous suggestions that have been made through our columns, in regard to the manner of tilling and enriching the soil; but there is need of much more being done, and we want every one to take a part. In the first place all should try to put in their wheat a little better this year than formerly—this all can easily do, without much additional trouble, if they have made a proper use of their own powers of observation, or have given any attention to the published ac-

counts of the experience of others. Then we want, also, that every farmer should make some definite experiment this year, which may put to the test some theory of science, or perhaps lead to some discovery that will prove of advantage to the farming community, when the results are made known.

"This may be done in a multitude of ways:—we have published numerous articles on the use of different kinds of manures and fertilizing agents, as lime, ashes, plaster, charcoal, &c.: now let each farmer who can obtain any of these substances try experiments with them, by dressing one portion of the field and leaving the other undressed. The same may be done with numerous other kinds of manure and substances to be found about the farm or neighborhood. Then, too, in the mode of tilling or preparing the land, there is unlimited scope for experiments; plow a little deeper than ever before, and if you can buy or borrow a subsoil plow, try that on heavy soils, and be sure in all cases to leave a portion of the field under ordinary tillage, so as to enable you to perceive the difference, if any.

"In the time and manner of sowing, and the kind of seed, there is also room for a multitude of important experiments, which will suggest themselves to the mind of every farmer: let them all be tried and the results published next summer in the Ohio [Southern] Cultivator, and the information thus obtained may be the means of adding millions to the wheat crop of Ohio [Georgia] for years to come, and bringing prosperity and happiness to the farmers themselves."

Breaking up Prairie Lands.

Col. A. McDonald, of Eufaula, Alabama, writing from Illinois, thus describes the farm of his relative and the manner of breaking up new ground in that State:

"Mr. A. McDonald was one of the early settlers of the country. He had an opportunity of selecting a choice place, and he made good use of the advantage he enjoyed; for certainly a more desirable farm than Elm Grove cannot be found in any country. There is about a section of the richest land, one-half timbered with black walnut, elm, cherry, the sugar maple; and the other half the richest prairie, finely watered. The manner of breaking up the prairie lands of this country interested me much. They hitch seven yoke of steers to one of their large plows—the steers, plow, and all, managed by one man, turning over from one and an half to two acres per day, which costs from $1.50 to $2 per acre. This work is performed in the finest style, the plow fixed to run on wheels."

Just think of such plowing as that, ye who never thought of going deeper than about four inches!—Seven yoke of oxen to one plow, and the plow attached to a pair of wheels very much like what is known among us as a carry-log! And then to pay TWO dollars per acre for this first plowing—a sum equal to what a great deal of our land would sell for even when new! Is there anything wonderful in the crops that are gathered from such ground, thus prepared for the reception of the seed?

Mr. Meriwether's Address.

Ever since we received a copy of Mr. Meriwether's speech before the Agricultural Society of Putnam county, we have been trying to find room for it in the Cultivator. The speech is quite too good to be spoiled by cutting it up into extracts, and rather too long for a paper like ours. Though there is no danger of its being spoiled by keeping, yet we will see if we can't get it in the next number of the Cultivator.

Decrease of Population—Study of Agriculture.

They are complaining about the decrease of population in the interior of the State of New York. And it is asserted, that unless something is done *by the Legislature*, to aid in improving the soil, half the rural population will go to the West, where land needs no improvement, for the present, at least. Wheat, the great staple of western New York, is now brought to Buffalo, from Illinois, Indiana, Michigan and Wisconsin, at five cents per bushel. In this state of things, it is confidently asserted, that, without the aid of science, the wheat growers of New York will have to give up the contest. Their condition is said to be still worse, who make wool, pork, butter, or cheese, according to the old system, on account of competition from the West.

Under all these discouragements, however, there is this to cheer us. It is said, that in spite of the prolific production of western soils, and the cheapness of freights on the lakes, there are still some farmers in New York who make money—and they do this, because they are enabled, by the lights of modern science, to give a triple value to every muscular movement, in whatever work they set their hands about. That is, their one head and pair of hands, can accomplish more in the same time, than the three heads and three pair of hands of those who work by the old rule, which, rejecting altogether the essence of brain, seeks to accomplish every thing by the use of mere elbow grease.

If these things are happening in the state of New York, from western competition in the growth of wheat, what may we not expect to happen in the production of cotton, when the rich and extensive cotton fields of Texas shall be brought into full cultivation, and into active competition with us who shall remain in the old Southern States? With our exhausted soils, and the markets of the world well-nigh glutted—not from over-production of cotton, but because the consumption of it is checked and restrained everywhere by despotic laws—the prospect of such competition would be appalling indeed, did we not know, that by setting our shoulders to the wheel, and calling upon science for aid, we may withstand it, successfully. We must study our profession carefully. We must bring all the light of science to bear on every process we engage in.

"Why should not"—asks Dr. Lee, of the *Genesee Farmer*, in an admirable article—"a person study the profession which he is to follow through life? Is the skilful cultivation of the earth, a pursuit not sufficiently honorable to be regarded as a *profession?* or is agriculture of too small importance to be *studied* as a science, as well as *practised* as an art? Why this resolute, this protracted, this hitherto successful opposition to the study of rural economy? We can not comprehend it.

"Is there really danger that the rising generation will know too much about the nature and properties of the things which must ever form all their annual crops? Are we apprehensive that, if they study and understand the unerring laws of Nature, so far as they relate to the improvement of the soil, and the production of human food, we shall have an over supply of the necessaries and comforts of life? Perhaps it is thought that nothing can be learned about the things that unite to form the 20 bushels of "increase," from one of seed, that God gives to reward the well directed toil of the husbandman. If this is the stumbling block, let us see if we can not remove it out of the way.

"A farmer sows one bushel of wheat, and harvests twenty. From what source does he derive the nineteen, to say nothing of the straw that supports the whole crop? Unless the whole increase is an entire new creation of matter, of course it must all come from somewhere. Now, it is obvious, that it would be of no consequence whatever, *where* this matter came from, or *what* it was composed of, provided God gave an "increase" precisely according to the amount of labor bestowed, irrespective of the folly, ignorance, or misapplication that might direct the same. But all experience confirms the truth of the remark, that Heaven does not so reward the labor of the farmer. The Author of our being interferes by no special providence to save the erring children of men from hunger, disease and death, provided they violate the laws of Nature. If an innocent child places its finger in a burning lamp, neither its innocence, nor its ignorance of the properties of fire, will save it from the full injury and pain of a burn.

"God has conferred upon talking man, not only a sense of just accountability to his Maker, and his fellow man, but *reasoning* faculties, memory, and other powers, which, when fully developed, will understand all the natural laws that concern his subsistence and happiness. These moral and intellectual faculties seem to be created to no purpose, unless they are awakened into life and usefulness, by the physical and mental wants of humanity. As a stimulus to rural industry, our Maker has created a necessity for man to "eat bread in the sweat of his face." This necessity is, moreover, "the mother of invention," and the parent of knowledge. Man's necessities arising from hunger, cold and nakedness, led him to the use of fire, and to make a thousand discoveries in the arts. These necessities still exist in full force. Undoubtedly the Creator could easily have formed every acre of land, so that the most ignorant man alive, might plow and sow it, and reap 100 bushels of wheat on the same, year after year for his whole life time, without impairing its fertility. But such abundance would have been an enduring bounty on ignorance, if not on vice and crime. *Knowledge* is necessary to renovate any large tract of country, which has been much injured by unwise tillage; and this knowledge can be best acquired by uniting the *study*, with the *practice* of agriculture.

"The study of agricultural science, implies no more nor less than the investigation of the laws of our own being, as social, physical, moral and rational creatures. It is only a question of *time*, when we shall begin to learn *what it is* that forms good bread, milk, butter, cheese, potatoes, beans, peas, lean meat, wool, and bone. We can not go on forever, increasing hungry mouths to be fed three times every day, and wasting to the tune of untold millions, the constituents of our daily food, and not *pay* for our folly.

* * * * * * * *

"Every body knows that there would be some difference in a loaf of bread, whether it was made out of a pound of good wheat flour, or a pound of oat straw! We are wonderful nice about our own food, but we expect our wheat plants to elaborate fat, muscle, brain and bone for us, and use materials as foreign from human flesh and blood, as copper, arsenic, and lead! We are all exceedingly fond of good bread, milk, and potatoes,

while we heartily despise the patient study that will inform us what are the simple elementary bodies that unite to make these articles of food. We greatly magnify the importance of blind hard work, as though man had the power to create a bushel of corn out of nothing, by dint of protracted and intense muscular toil. To study the nature and properties of the substances that Nature *must* have to form 80 bushels of this grain on an acre, is a perfect waste of time! A knowledge of these things can be of no possible use to the practical farmer! Who cares to know what there is in a kernel of corn, or a sound, mealy potatoe? These things can be made out of nothing, *only work hard enough!* A gallon of human sweat, spread evenly over an acre of land, is better than all the agricultural science in the world, because it can be sold any day in August for *fifty cents!*

"If it were not for the indifference of farmers to the spread of agricultural knowledge, rural industry would raise at once 50 per cent in productiveness and value. So long as the tillers of the earth shall work 12 or 15 hours in 24, to make something out of nothing, the balance of the world will give them but a precious little for their service. And why should they? If a farmer gives as much labor for one bushel of corn or wheat as he should for three, ought he not to exchange his badly directed industry, by giving three day's work for one with those that *study* their business, and make every hour's work tell to the best advantage? We can not blind our reasoning faculties, and then plead ignorance of the things that form our annual crops, as a reason why we should have more than the market value for our produce. There is no alternative but to lessen the hard work now expended in growing all our agricultural staples, by the aid of knowledge. If we cruelly withhold this knowledge from our sons, we indirectly give a bond that they shall be the hewers of wood and drawers of water for the better informed, and that too, at the smallest wages, all their days.

"Kind reader, if you have a son, and believe with us, that the study of the laws of Nature will do him no harm, purchase for him Mr. Jas. F. W. Johnston's "Lectures on Agricultural Chemistry," latest edition, which will cost you but $1,25. Let him buy as soon as he has thoroughly studied Johnston, Boussingault's "Rural Economy," which will cost a dollar and a quarter more. These invaluable works should be in every common school library in the state. We commend them to the attention of all teachers of young men in academies, and other seminaries. As Text Books, they may be regarded as standard works in all debates; although they differ in their respective analyses of certain plants, such as wheat, potatoes, and a few others. But plants differ in the proportion of their elements in different soils. The analyses of both are doubtless correct in the particular cases to which they refer.

"There is scarcely ten farmers in the whole State that feed all their cultivated plants, including fruit trees, grape-vines, and strawberries as they should be fed. The same is true, to some extent, in regard to feeding, with the most appropriate and economical food, all domestic animals. How important, as well as interesting, is the study of the organic structure of all the living things kept on the farm! These organized vegetable and animal beings possess many *organs*, and each organ has its peculiar office to perform.

"Do we work *with* or *against* the purpose of Nature, in our treatment of all these vital functions? Are we sure that we obtain the largest possible crops of peas, potatoes and corn, from any given amount of land and labor? or the largest return in good pork, for the corn, peas, and potatoes consumed by our swine? How is it in regard to the production of grass, carrots, beets, beef, butter, cheese and wool? Whose wool, worth 30 cents a pound, costs him the least money in land and labor? Whose cheese and butter yield him the largest profit or compensation for his industry? When we export 1000 tons of cheese to England this fall, how much truly valuable matter have we drawn from our pastures? Where are the *precise things* in boundless quantity, that makes cheese, wheat, and wool?

"What madness to resist the STUDY of these things. The great "Empire State," with its five hundred thousand field laborers, can not support *one* agricultural school!

"'O shame, where is thy blush?'"

Distinguished Farmers.

We have had great pleasure in publishing in recent numbers of the CULTIVATOR, accounts of the farms and the management of Mr. CALHOUN, Mr. CLAY and Mr. VAN BUREN, and we have no doubt those who read these accounts had an equal amount of enjoyment therefrom. We now occupy a pretty large portion of our paper —could it be better occupied?—with an account of the farm and management of another distinguished statesman—Mr. WEBSTER. It *is* truly gratifying, as the writer remarks, to see men of such signal abilities and exalted repute, though differing in politics, united and ardently devoted to the great cause of Agriculture.

VISIT TO THE FARM OF HON. DANIEL WEBSTER, *Marshfield.*—We have been gratified by a visit to the farm of this distinguished statesman, and had the pleasure of holding converse with him as a farmer in his retirement, and who, by his urbane and friendly manner makes one almost forget that he is in the presence of one of the greatest intellects of the age. As a public man, he is well known, but not as a citizen and "the Farmer of Marshfield"—at home, on his farm, or among his neighbors. Here the mind is unbent—the stirring scenes of political life are apparently thrown aside and forgotten, and the farmer may approach him on equal ground, and however experienced he may be in the one pursuit of his life, he will find Mr. Webster at home on the subject of agriculture, with a disposition as ready to impart, as he is to receive information, on a business which appears to be more his pleasure than his profit. But if his farming does not result in pecuniary profit, he has the satisfaction—which, in a mind like his, is prized far higher than pecuniary gain—of countenancing and encouraging by his example, the great agricultural interests of the nation as well as the influence he exerts on all suitable occasions to promote them.

His farm is extensive, and that we might have the best opportunity to see every part of it, his foreman with a carriage, was at our service, to take us over it, and explain the various operations and experiments that are in progress. Mr. Webster also devoted a portion of the time we remained on the farm in pointing out to us the improvements he had already made, as well as those he had in contemplation, and related many interesting incidents in the history of the family of the original proprietors of his farm, and of events which transpired in the early history of this ancient town.

* * * * * * *

Mr. Webster's farm contains about *fifteen hundred acres.* This large area embraces a great variety of soil, about 300 acres of it salt marsh, the remainder very diverse: some portions of it may be considered of first quality, other sections medium, and some of it rather inferior; but none so poor that good crops cannot be produced with good manuring. The situation is a fine one for a stock farm—and if good prices for good beef and mutton could be obtained, it might be a profitable farm for that purpose. What adds much to the value of the place is, the facility with which sea manure can be obtained. It is said that there are seven miles of beach, reckoning all the indentures and various outlines of the shore which skirts the farm. Here large quantities of kelp are annually obtained, and in some seasons white fish to any extent are caught. With these natural resources so near at hand, the farm is rapidly increasing in value and productiveness. Wherever these fertilizing substances have been applied their beneficial effect is obvious. A large portion of the farm is devoted to pasturage, which feeds not only Mr. Webster's large stock of cattle, but many others of his neighbors, which are pastured by the week or by the season.

The mansion house of Mr. Webster makes quite an imposing appearance as it is seen from the road, having recently been fitted up, and large additions made to the old part, which was originally a square house, two and a half stories high, with a wing extending back: a wing containing a suit of rooms, including a spacious library, has been added, making an extensive front, with a piazza the whole length, extending round the ends of the building and part of the rear. The old and new parts of the building harmonize very well. Comfort, convenience and neatness are more conspicuous in the arrangement, than any effort at display. The mansion is situated 30 or 40 rods from the public road, and is approached by a broad drive way bordered by a hedge and belt of trees and shrubs. In front of the house is a fine lawn of five or six acres, dotted with trees in groups and single, and ornamented near the dwelling with fanciful beds of flowers, cut out in the smooth sward. But the most striking object which meets the eye at first sight, is a majestic elm tree, near the east corner of the house, which forms a complete bower. It stands on an oval grass plot, which makes a fine carpet for the bower. At a distance of eight or ten feet from the ground the branches extend in every direction horizontally, gently curving over till they rest upon the green sward, excepting on the side next to the house, where it has been necessary to cut out some of the lower limbs, that carriages may pass to the eastern door. The branches on this side nearly touch the house, and form a complete canopy to this entrance. The longest diameter of this tree bower is 94 feet—perhaps 70 the other way. Seats are arranged around the tree near the trunk, where is a most delightful retreat, especially in such a day as was that when we enjoyed its shade, the thermometer indicating the heat as near 90°. The tree is said to have been planted 80 years ago.

The section of the farm on which the house stands, contains about 40 acres, and is bounded on three sides by a wide belt of young trees, through which there is a winding walk. In this area are included the lawn in front; to the west, the orchard; in the rear, grass, and a large fish pond, ornamented with a boat moored upon its surface, which an apprentice boy, while engaged in painting the house, took a fancy to convert into a mimic man-of-war; to the east, an extensive fruit, vegetable, and flower garden, of 3 or 4 acres; and beyond this, a conical hill, crowned with a summer house. When we visited this farm five years ago, this hill had the appearance of a miserable gravel-knoll, with a few stinted shrubs and trees. It was now covered by a luxuriant growth of young trees and shrubs, from 10 to 12 feet high—among them many locust and other trees which had been raised from seed, and other species which had been transplanted. The belts had been formed in the same way. In rear of the garden,

and at the foot of the hill, is an extensive poultry yard, well stocked with every variety of domestic fowls, with a pond for the accommodation of the aquatic tribes. In the rear of the house, at the N. E. angles, are carriage houses, stable, and other outbuildings, and a little further back, a large and well constructed barn.

From the piazza of the house, beyond the belt of trees, and on rising ground, in a westerly direction, the eye rests upon extensive fields of grain, roots, &c.; southerly, a sheep pasture, in which we saw the Leicester sheep, and further to the east, woodland.

The house of the head farmer is seen to the east, as the visitor enters the avenue to the mansion, and back of it extensive ranges of cattle-yards, piggery and sheds, and another fine large barn, now in the process of building, and nearly finished. There is no cellar under the barn, but Mr. Webster has hit upon a method to save every drop of the liquid manure, and in the best possible way. The planks composing the floor of the cattle's quarters, or *byre*, as the Scotch call it, are laid with an opening between them of about one half inch, and so arranged as to be easily taken up. The idea is to place about two feet of loam, or other earth, under the floor; this will absorb all the liquid part of the manure as it runs down through the openings, and in the spring will be converted into the finest manure, when it is to be removed, and replaced by fresh mould. Instead of having the upper part of the barn tight, he has purposely had it finished with crevices between the boards above the byres, to admit the air; but the byres are made tight by battens nailed on the inside. Instead of losing all the room over the drive-way, as is the case in barns generally, there is a flooring over two-thirds the length, leaving room for a large load of hay on the floor below, a door being provided for the oxen to go out at the end of the drive-way, while room is thus made for at least 20 tons of hay more than if the barn was finished in the usual way. Byres are arranged on each side of the drive-way, and yards are being made on each side of the barn, so that the stronger cattle may be kept by themselves, and prevented from injuring the weaker. The yards are so arranged as to receive the sun, and protected by sheds from cold winds. In addition to the two large barns we have mentioned, we noticed others at distant points from the mansion.

Manures and Crops.—We have already remarked that fish and other sea manures were extensively used on Mr. Webster's farm. Of the beneficial effects of fish and kelp on corn and grass, we were an eye-witness. A field of corn of 15 acres, had been divided into four sections, and manured as follows: 1st section with fish; 2d, kelp; 3d, stable manure; 4th, guano. On the three first sections, the manures were spread upon the sward and turned under; the section where the guano was applied, was turned over without manure, and the corn dressed with the guano soon after it had appeared above ground, and a second dressing given at the last hoeing, at the rate of 300 lbs. to the acre. Forty loads to the acre of stable manure, were applied to the section dressed with that substance: the quantity of kelp applied was indefinite, the ground having been well covered with it, without counting the loads. Fish were applied at the rate of 10 loads, of 13 barrels each, to the acre. Taking the field as a whole, it gave the appearance of a remarkable heavy crop. The section manured with kelp, took the lead; that with fish, next; that with stable manure, next; and the section with guano, behind the whole. The quality of the soil of the different sections was nearly equal, excepting that which was guanoed, which had the appearance of inferiority. The corn on this section, we were informed by the foreman, looked very unpromising in the fore part of the season, but was now evidently gaining more rapidly than that on either of the other sections, and he said it was impossible to make a just comparison until after harvest.

On a mowing field, we saw the effects of fish that had been applied since the grass was cut. The contrast between that portion of the field which had been "fished" and that which had not, was very striking, in the deep green luxuriant growth of the aftermath on the one, and the russet-brown, dead-like appearance of the other. But who can describe the *odor* which came from that field! All the old fish-oil stores on Long Wharf combined, would not produce the like, or any approach to it: and then the swarms of large green flies that covered the fences and trees! The plague of flies in Egypt, could hardly have exceeded them in numbers. The decaying fish furnished them a rich feast. Luckily, this section of the farm is remote from any human dwelling. But however unpleasant this vile smell from the rotting fish may be to a stranger, a person soon becomes accustomed to it, and as the unpleasant gasses arising from the decomposition of the fish, are said not to be injurious to health, and as this manure will double or treble his crops, the farmer should not be deterred from using it by the disagreeable character of the smell.

We noticed a small patch of corn in another place, that had been manured with guano in the hill, and afterwards received a fish to each hill as a top-dressing: the corn was of the deepest green, and of the most luxuriant growth.

We have often heard it asserted that fish manure, after exciting the land to produce one or two heavy crops, leaves it in an exhausted state. This opinion is at variance with what we witnessed on a pasture that had been "fished" four years since. We compared it with a pasture adjoining, both originally of the same quality of soil, or differing but little. The pasture that had been "fished," was thickly coated with fine grass, and notwithstanding the drought, still produced the best of feed. The neighboring pasture was dried up, mossy, and apparently of little value. Another pasture was shown to us, which had been manured with fish nine or ten years since, and before the application was almost worthless: it has since produced excellent feed, and is now in good heart. These results would seem to show that fish manure is not so evanescent as it has been represented by writers and others.

Mr. Webster said he considered one load of fish was equal to three loads of stable manure, and afterwards appealed to his head farmer, for *his* opinion upon the subject, who thought a load of fish equal in value to five loads of stable manure.

Sea weed is used in the piggery and barn yards, and every means of increasing manure from these sources, appear to be availed of.

Leached ashes has been used to some extent, and proves a valuable manure on the light soils which compose a part of Mr. Webster's farm. On a ten acre lot of very light land, 3000 bushels of English turnips were raised last season, with no other manure than leached ashes, and at an expense of only 73 dollars. About four acres of the same lot were sown down to clover, and the balance with oats, for the purpose of plowing in when green, to enrich the soil. A very light dressing of guano was given these fields. The oats were so promising, that Mr. Webster altered his mind with regard to their disposition, and concluded to let them stand and mature; and on this very light soil, with no other manuring than leached ashes last year and a small quantity of guano this, we now beheld, ready for the cradle, a heavy crop of oats. The clover on the other part of the field covered the ground, and was soon to be plowed in, as was also the stubble of the oats, for seeding down to rye.

A tract of ten acres, of the same quality of soil, was covered with a vigorous growth of buckwheat, which the plowmen were engaged in turning under, preparatory to rye. Another large strip was devoted to beans, and four or five acres to ruta baga, sown broadcast, and not sufficiently advanced in growth to enable us to form an opinion of the probable result of the harvest. A lot of three or four acres was devoted to mangold-wurtzel and sugar beets. In some parts of the field, the crop had been thinned by the worms, and causes attributed to the season or the seed—but the plants generally were thick enough to ensure a heavy yield. Another large section was devoted to English turnips, which, of course, had not yet begun to make much show.

Fifteen or twenty acres of the farm are devoted to roots, which are fed to the stock in winter. Last autumn and winter, a lot was fed off the ground by sheep, according to the English practice.

Spring wheat has generally succeeded well on this farm, but the present season has been rather unfavorable. Samples that we examined from the crop stored in the barn, did not indicate a very heavy yield; the grains did not look so plump as samples we have seen from this farm.

The yield of English hay this season, has been estimated at about 200 tons. The salt hay is mostly let out to farmers back from the shore, to cut on shares. The marshes yield about the same quantity of hay as the uplands. The quality of the marsh hay varies; some of it is almost equal in value to good English grass, while some is fit only for bedding or manure.

The farm appears to be well stocked with apples, pears, peaches, plums, grapes, &c.—Among the apples we noticed the High-top Sweeting, a variety that may be found on about every farm in Plymouth county, and in some orchards there appeared to be an overstock of this ancient and highly esteemed apple; but we are sorry to say there is hardly a thrifty tree to be seen; the variety seems to be on the decay.

The stock on Mr. Webster's farm, taking it all together, cannot be surpassed by any in the State. The last season he wintered ninety head. The cows are generally of the Ayrshire breed, either full-blooded or mixed. They originated from a cow imported by the Massachusetts Agricultural Society, and a bull imported by Mr. W. This animal is finely proportioned, silky, short-haired, and equal to any creature of the kind we have ever seen. The cows are also beautiful, and give abundant evidence of their superiority in the quantity of milk they produce—having averaged, in the first of the season, 20 quarts each per day. He has eight milch cows of this breed. We saw in a pasture at some distance from the house, 10 two-year old heifers of this blood, that could hardly be excelled in point of symmetry and general beauty, having the glossy hair and admirable mixture of colors peculiar to this breed.

For working oxen, Mr Webster prefers the Devon breed of which he had ten or twelve yoke, in excellent order, besides steers. He had sent a drove of fat oxen to the Brighton market, a few days previous to our visit.

Of sheep, he has the celebrated South Down and Leicester breeds—more esteemed for their excellent mutton than for their wool. Wethers are purchased at Brighton market, in autumn, and kept through the winter on turnips, hay, and a little grain, and when fatted in the spring, sold to the butcher. This has proved to be good husbandry, affording some profit, and increasing the manure heap.

The Mackay breed of hogs is now the only sort kept on the farm—the Berkshire having been tried and discarded.

We conclude this hastily penned and imperfect account of our most agreeable visit to this extensive and well conducted farm, by remarking, that the interest taken in Agriculture by such men as Mr. Webster, Mr. Clay, Mr. Van Buren and Mr. Calhoun—all of whom are engaged, and are proud to be, in the culture of the earth—is a scathing rebuke to those weak-minded or wrongly educated persons, who look, or affect to look, with contempt upon, and to consider as degrading, the noble occupation of the farmer. And truly gratifying is it to see men of such signal abilities and exalted repute, though differing in politics, united and ardently devoted in the great cause of agriculture—the basis of national wealth and national prosperity—and whose followers constitute alike in peace and war the main bulwark of the country's welfare and security.

Original Communications.

The Crops--The Drouth--Practical Hints.

Mr. Camak:—Having been preserved by a kind and overruling Providence to reach my native State, on my way home, I feel it due to my brother farmers (for I hope every Georgia farmer takes the Southern Cultivator,) to give them some account of what has fallen under my observation. Since I last wrote you from Illinois, I found the grain crop of the West promising an abundant harvest. This is peculiarly fortunate, indeed, at this time, as we have suffered so severely in all the South. For, I found, in passing through the State of Virginia, as well as North Carolina and South Carolina, and as far as I have came in Georgia, that the crop is literally cut off. Indeed, I have scarcely seen a field of corn that would yield over half a crop; and, from the best information I can get, this unfortunate state of things is general. A very natural inquiry comes home to every man: what is best to be done under this state of things? The answer is promptly given: Let us sow largely of the turnep crop; sow largely of the winter grains, such as wheat, rye and the hardy kinds of oats. Then, in the commencement of the fall and winter, use great economy in the consumption of what we have. By pursuing this course, and in the meantime, commence taking the example of our more prudent Northern farmers, set about saving and making manure for the year 1846, we will, I hope, be prepared against future drouths, at least as far as human foresight can prepare, particularly if we will pay much more attention to the provision crop generally, than we have heretofore done—that is, plant a much larger proportion of our lands in a provision crop, and much less in the cotton crop.

Having mentioned the subject of manure, let me tell my friends who cultivate the soil, that the sooner we turn our attention to that important part of husbandry, the better it will be for us. In passing through the States of New York and Pennsylvania last month, (August,) I found the farmers every where hauling out large quantities of manure. Indeed, from the size of the farms and the quantity of manure, I was at a loss to know how they managed to prepare so much of it; for, from the number of cart loads that they put on an acre I supposed they intended to spread it broadcast. And such was their attention to the soil, that they had previously plowed up the fields for its reception. Now, I don't believe in imitating the North in everything; for, from all I have seen, I would be the last man that would quit the South and settle in that cold region. But their system of industry and economy is worthy of all praise. If we would carry it out to the extent they do we might soon make our delightful country the garden spot of the world. Let us, in all the South, get up, as New York has done, State Agricultural Societies, and County Agricultural Societies. Let us universally, as farmers, encourage the agricultural press, and in a few years the whole face of the country will present a very different aspect. We will hear no more of hard times, but all will be flourishing and happy. Your friend,

Alexander McDonald.

Macon, Ga., September 15, 1845.

Bermuda Grass--Sweet Potatoe.

Mr. Camak:—How Doctors differ, or if you please, how we Bermuda grass men disagree as to how to give the death blow to this monster, Bermuda. Well, this is all well enough. The object is, to get at the experience of all; then sum it all up, and see who is right; and see who has learned to kill it so that it will stay killed: or to see if he who thinks he kills this grass, has not killed the soil, I think I must say, *deader* than the grass? And let me say, in this place, I feel no wounds inflicted, at having my plans controverted. I have stated, and my belief is, that shading crops—such alternate crops as peas in summer, and wheat or barley, in fall and winter—is the best. Mr. Rheney, of Burke, says it wont do; that hoed crops, with preparatory plowing, is the thing. According to his own statement, by a great deal of hard work, he has killed both grass and land, and that by plowing and hoeing. This he may do in Burke, where the land is, I presume, sandy: and I stated, that it was much easier to manage it (if not to kill it,) in sandy soils. But if he will come to old Greene, and kill it after his plan, on our large fields of stiff, red clay soils, and with any thing like the usual crop to the hands, and especially, if he will kill it without injuring the land, I think we will not only give him the silver cup, but fill it with kindness, and that to overflowing. For it will profit us but little, to be shown how to put an end to the ever-lived Bermuda, unless in so doing we can treat the soil more kindly. My plan had in view, not only the killing of it, but in doing so to have the land improved.

I would not have Mr. R. think, that I question what he says. I am glad he has said what he has, as we invite the experience of all, on this all-important subject. I only object to the state it leaves the land in, by his own statements of his process of destroying it.

We are very much upon the plan of trying to improve our lands in these parts, and we have been saying, or I might say hoping against hope, that Bermuda was coming in (to be what red clover was to the North,) to aid us. But enough, for I am pausing, to know, what more to say or think of this blessed pest, (as I must call it, till I can get a better name,) and these remarks are only in reply to friend R. of Burke.

My main object in taking pen in hand, to contribute my mite to the Cultivator, was, at this time, to do more immediate good to the community, than R. or I shall do in discussing the merits of Bermuda grass; and that is, now that we make but little to live on this dry year, to try to tell my friends and neighbors how to keep that little, when we have got it.

The *sweet Potatoe* is a favorite crop with me. It is one very difficult to keep, after you have made it, without a great deal of trouble; and they loose much of their flavor, if the least unsound. The best way to keep them good, that I have ever tried before my now proposed plan, is the old fashioned way of putting up in large hills or piles, and covering with earth. In some seasons, they will rot in this way.

I have mainly kept mine now for the last two years, *perfectly sound*, by putting them in a dry loft, on a tight plank floor, and covering with *cotton-seed*, about 6 or 8 inches thick. Any garret or loft, that is fit for nothing else, will do for this; for it may be only the room made by the roofing or rafters coming down to the floor, and scarcely high enough to stand erect in the centre: yet this is the very shape you want your potatoe-pile to be in, running the whole length of a long roof, if you have the potatoes; letting them lie here till cold weather is about to set in, so that they get perfectly dry and cured. Then cover with cotton seed, and you will have good fresh roots, till this time of the year. I can now show some as sound as the day they came out of the ground. The advantage over the old hill practice is, that it is not half the trouble to fix, is always ready to get at, to take out more or less, and when you take out, begin at one end of your roof-shaped pile, by displacing the cotton seed; when you have got out what you want, simply throw back a few seed, where you have just taken from. Try it, and it will do you good.

And, now, Mr. Editor, let me say in conclusion, as Sam Slick says; "the best land, with hard usage and constant cropping, will *run out*." So we novices, with pen in hand, and a desire to scribble, and not much in the head, will *run out*; and to make out my piece and fill my sheet, let me, through you, object to this anonymous writing in the Cultivator. There's my Bermuda friend P. of Walton, and there's your "Agricola's," and "Salamander's," and "Cotton Planters;" and next, I expect, we shall have our "Potatoe Eaters," &c. &c., Come out with your true names, gentlemen, and let us see who you are. And if we differ, and can't settle it by writing, let us know who you are, that we may go and see you, and settle the difference by word of mouth; surely, if we are engaged in a good cause, we ought not to be ashamed of our names. Subscribe your true names, as I do mine. J. Cunningham.

Greensboro', September 19th, 1845.

Sheep and Wool.

Mr. Camak:—Proof is unnecessary for the conviction of any intelligent mind familiar with the character of the soil and climate of our extensive pineries bordering on our rivers and tributaries, that they possess superior natural advantages to all other lands for successful and profitable sheep husbandry. Though almost in a state of nature, they may be made, in a few years, to yield returns in this branch of husbandry, unequalled by the most productive agricultural districts in the State. The scattering flocks of fine looking sheep in our pine land counties, fully demonstrate its practicability upon an extensive scale.

If sheep husbandry is made a source of immense profit in countries where land costs thirty to fifty dollars per acre, and the climate requires them to be fed eight months in the year, and that, too, on dry food, how much more available are our pineries at 10 to 40 cents per acre, with a genial climate and a soil of perpetual herbage? If the bleak States of the North raise their millions, why may not Georgia do the same, with greater advantages of soil and climate? With the same agricultural encouragement, she can raise finer sheep and double the number of any of the Northern States. And once began upon a liberal system of husbandry, we will see the husbandman of those States transplanting his flocks from their snow-capped mountains to the verdant plains of our noble and extensive pineries.

To those familiar with the natural advantages of our pine land counties, the question must force itself upon the mind, why have we neglected so long the blessings that the God of nature has given us? In truth, we are the slowest people in creation to profit by the force of example. Georgia is capable of raising millions of sheep, and in a few years may be made not only to supply the demand of her own manufactories, but to export millions of dollars worth of wool, from lands now entirely unproductive.

The most valuable of our pine lands for the raising of sheep are the counties included in what is termed Southwestern Georgia. Their variety of herbage and fertility of soil render them the most desirable lands in the world for the grazing of sheep. The counties on the bold and gushing Flint and its tributaries, from Dooly and Sumter to its junction with the Chattahoochee, seem designed by nature for sheep walks of the most novel and romantic kind. Within this area of country, including Lee, Baker and the adjacent counties, can be raised a larger number of sheep, to greater advantage, than in any country of its extent upon the habitable globe. From its great natural fertility of soil, surrounded by a vast region of grazing lands, and abounding in the richest and most luxuriant herbage, it must, one day, become the *centre* of a great sheep country. It is there the shepherd will delight to dwell. From its smooth and even surface and freedom from all underbush, the eye at a single glance can scan thousands at feed. Such is the character of a large portion of the pineries in that region of the State. There also may be seen what is often termed "the richest lands in the world," for the earth, indeed, "seems to teem with riches," and nature to have blended all her excellencies and exhausted her storehouse in the production of a virgin soil.

In contemplating the great agricultural resources of that region, we are naturally led to lament the destiny of unhappy friends who have overlooked the claims of their own Georgia, and sought homes upon lands in other States not half so rich, and for which they have paid three, yea, in many instances, five times their value. *Sic transit gloria.* What Georgian, who has passed a winter in that region of his State, but dwells with feelings of ecstacy and delight upon the sojourn.

The next of our pineries most desirable for the raising of sheep, are the counties upon the Ocmulgee, Oconee, Altamaha and Ogeechee rivers and their tributaries. The most intelligent men in these counties concur in their experience that this is the most profitable live stock they can raise. Sheep require little or no food during the severest winters, and thrive well on herbage alone. Your correspondent remembers well the information afforded him by a Representative to the Legislature from Irwin county a few years ago, that with only the care of a shepherd he could raise one thousand sheep easier than he could then fifty in view of the homestead. And that under a judicious system of sheep-husbandry in Georgia, Irwin county alone was capable of raising 50,000 head. Practical men have thoroughly demonstrated the fact, that every breed in this country can be raised as profitably upon our pineries as in any part of the Union.

It is a fact, too, worthy of observation, that sheep on our pine lands are exempt from the diseases that scourge flocks of other countries. If they escape the attack of their natural enemies—the dog and the wolf—they rarely ever die until old age carries them off. They manifest too, a remarkable quietness and content never observed in flocks elsewhere. And in the eye of an old buck of our pineries there is a leer of arrogance with an air of gracefulness in his step that gives him a knightly and lordly appearance.

The middle range of counties in Georgia between Scriven and Franklin, on the Savannah, and Stewart and Heard, on the Chattahoochee, are capable of sustaining thousands of sheep, though not in such large flocks as those counties suggested before: yet this region of our State affords great advantages to our planters to engage to the utmost of their means in this branch of agricultural industry.

Above the points defining the middle range are the adjacent mountainous lands. These are not surpassed by any sheep lands of similar character in any part of the world. Upon them also may be raised with great profit and success every breed known to us. The celebrated Alpaca will, one day, ruminate quite as free upon our mountains as upon his own Cordilleras. Endowed with great strength of constitution and capability of sustaining himself upon the coarsest food, may we not hope to see this noble animal browsing upon our mountain tops, the pride and wealth of our enterprising and patriotic agriculturists?

With hundreds of thousands of acres of wild lands, yielding a scanty support to the few unfortunate of our people whose lot has been cast without a single ray of hope in these sections, cannot their condition be relieved by the dawn of a brighter day? Yes; the beginning of an enlightened system of agricultural industry in Georgia will afford them a more cheerful prospect. And where nothing now presents itself to the eye of the traveller but the dull monotony of vast uncultivated tracts of country, their hills and plains will be covered with green pastures, and homes made cheerful by the sight of the shepherd and his grazing flocks of sheep.

Then why should a State, striving to promote public and private interest, delay longer in a measure fraught with such manifold blessings to her citizens? Here nature has opened a field rich for a harvest. Come ye! who wish to reap the product of her noble work. Legislator! put your hands first to the handle and the work is begun. Patriot! do that for your country that will secure you the gratitude of your countrymen—your success will feed the hungry and clothe the naked at your door. You cannot achieve for your State a nobler destiny than the encouragement of a wise, liberal and profitable branch of agricultural industry. Respectfully,

Reclusa, 10th August. JETHRO.

USEFUL AND CHEAP.—A parlor srove has been invented with a *gasometer* attached, by which as much gas can be extracted from the coal during the day as will serve for light during the evening.

"The Science of Good Husbandry."

MR. CAMAK:—Under the above caption Xenophon has detailed a conversation between Socrates and Ischomacus—of which a sketch, in part, may not prove unacceptable to the readers of the SOUTHERN CULTIVATOR. Socrates was considered the great founder of ancient moral and mental philosophy—and his name stands out from the past, the most conspicuous and shining light of antiquity.

Speaking of the improvement of estates, it was observed that stewards or overseers should be as good as the master—as careful and unremittingly industrious *as if the owner were present* during his absence. None other would avail. An estate is not strictly *property*, unless it be *profitable*. The time and attention of owners should be bestowed on a plantation; as a Persian king being asked what made his horse so fat, replied, the "eye of the master."

Money itself is valueless in hands extravagant or unknowing how profitably or felicitously to invest it. Everything is valuable only by its right use, more than possession. The best opulence is to be satisfied with your estate, whatever it be. But a good, thrifty and prudent wife enhances one's wealth by retaining and preserving what he brings in. And Ischomacus praised his wife for an obedient, amiable and diligent woman; hence he was admired by Socrates as a thrice happy man, well meriting the popular title of "*the Just.*"

Work should be done with regular diligence and constancy, but not so headlong as to fatigue too much.

Rich men should not be above working manually, with their own hands. Cyrus, the greatest monarch of Persia, was instanced as having *daily labored before meals*, and his extensive and beautiful orchard, was mainly laid out and planted by his own hands. But to be engaged in any way, at the study, or in the field, or the workshop, was in Socrates's opinion, commendable employment. I quote some of his translated words:

"By husbandry the ground gives us every thing necessary for food and nourishment, and such things likewise, as afford the greatest pleasures. Yet, though it gives us plentifully of all kinds of things, yet it does not allow us to reap them in sloth and idleness; but excites us to health by the labor it appoints us. * * * The practice of husbandry makes men strong and bold—enabling them to defend their country. What science is there that brings man more advantages for his labor. * * * He was surely a wise man that said husbandry was the mother and nurse of all the other sciences; for when she flourished all the other sciences and faculties fared the better; but when the ground lies uncultivated and brings no crop, all the sciences and arts are at a loss by land and sea. * * * It is a healthful employment, breeds good men, and occasions generosity of spirits and good will towards one's friends and country."

Ischomachus instanced the treatment of slaves: to carefully reward the diligent and lay as many hardships as you can on the idle and careless. Bad managers and fretful masters make bad servants. Be firm, but not outrageous. Nothing spoils or desponds a good servant so much as to see the idle and unworthy put on a level with him, or praised and promoted before himself. Dishonest overseers or drivers, no matter howsoever industrious and diligent, are not to be continued. Honesty in such is as valuable a quality as industry. "As to slaves," said Socrates, "we should not act on the laws of Draco and Solon alone, by punishing the bad, but upon those also of the Medes and Persians, by rewarding the good and deserving."

"Husbandry is profitable," continued Socrates, "to proficients, but exceedingly unprofitable to the ignorant, though not requiring length of time to understand. The principal difficulties are as to the soil. On it philosophers are rather occult; yet, the constituents of soils may be discovered by observing what best grows upon them."

"Plow fallow lands in the spring, as it is too wet in winter and too dry in summer. Weeds and grass turned in before the seeds mature improve the soil, as also green crops plowed in," observed Ischomachus.

"The sun's rays correct the rawness and sourness of earths. Not convenient to sow when dry. Good sowing requires experience, as seeds should be equally distributed over the ground," remarked Socrates.

"Ditch, to drain off superfluous waters; manure at every rate must be had---improvidence to be without it. Weeds laid under water rot, and constitute manure equal to dung. Water, in a still place on earths, too, convert them to manure.

"In planting trees never exceed three feet in depth, for any kind but the olive. The best width of the hole is two and a half feet. In planting the olive tree have clay at the bottom," said Socrates. "The land by its production is always the best teacher of its fitness. Dry and calcareous earths should be laid on sour unproductive soils." This, I think an idea of the *lime* of the moderns.

Socrates and his friend Ischomachus, then the best husbandmen in Greece, agreed that generous masters, especially with good servants, are more successful than the indiscriminately cruel.

It would appear from the above sketch of a long conversation, that the ancients were but little, if at all, inferior to the moderns in the cultivation of the soil. Even the experiences of two or three thousand years, are, to many, at this day, as unknown and unpractised as if Greece and Socrates never existed. Thus goes the world, folly and ignorance being always the same disagreeable things.

As the ancients remarked, the great difficulty to this day is, in finding the proper constituents of soils. They were ignorant of our gaseous derivations and chemical properties, or they might have handed down to us a manual, obviating many difficulties with which we have now to contend, notwithstanding our boasted wisdom. J. J. FLOURNOY.

Wellington, September, 1845.

Farmers' Club of Upatoie.

MR. CAMAK:—On the 5th instant an Agricultural Society was organized at this place, (under the above name,) by adopting a Constitution and electing as officers for the ensuing year—

JAMES H. JONES, Sen'r., President.
NATHAN RENFROE, and ALBUT JOHNSTON, } Vice Presidents.
R. W. CARNES, Corresponding Secretary.
DR. CHAS. M. SMITH, Rec. Sec. and Treas.
THOS. H. KENDALL, Librarian.
WM. W. WILLIAMSON, WM. B. ROCKMORE, WM. TINSLEY, JOHN L. SMITH, and WM. GRAHAM, } Board of Managers.

Our Club numbers forty-five members. We desire to be considered one of the *family*, and confidently expect countenance from other Associations, and such information and instruction from our brother farmers elsewhere as their convenience will permit. Very respectfully,

ROBT. W. CARNES, Corresponding Sec'y.

Upatoie, September 16, 1845.

MANURE MAKING.—There is one means of making manure on every farm which is too commonly overlooked or not availed of—we mean, from the wash and waste liquors of the house. Cart a load of loam near the outlet of your sink, and carry the spout on to it; shovel over the heap occasionally, and in six or eight weeks the mass will be enriched, and a fresh lot may be brought to undergo the same process. Thus, in the course of a year, several loads of manure may be made at a trifling cost, and of a quality hardly inferior to that from the barn-yard. This hint is worth something.—*N. E. Farmer.*

From the Genesee Farmer.

The Fruits and Fruit Trees of America.

By A. J. Downing, *of Newburgh, N. Y.*

This work, for which we have been looking with considerable anxiety for some time past, has at length made its appearance; and from the rather cursory examination which we have given it, we can say that it is the most complete and useful book of the kind yet produced in this country.

This was to be expected, not so much on account of the peculiar qualifications of Mr. Downing, as of the great facilities afforded for the compilation of such a work, by the recent careful and systematic investigations of European as well as American Horticultural Societies, and the increased general attention given to fruit culture everywhere.

The work has evidently been prepared with a great deal of labor and care, and with a view to make it as perfect as possible at the present stage of American experience in this department. We cannot convey to our readers an idea of the importance of the work any better than by giving a sketch of the various subjects of which it treats.

Chapter 1. Treats of the production of new varieties of fruit.

2. Propagation of varieties, grafting, budding, &c.

3. Pruning.

4. Training.

5. Transplanting.

6. Position of fruit trees, soil and aspect.

7. General remarks on insects injurious to fruit trees.

8. The *Apple*—history, uses, propagation, planting, pruning, insects injurious to it, gathering, keeping the fruit, cider making; and a description of 186 varieties, with engraved outlines, natural size, of upwards of 30 varieties.

9 The *Almond*—history, uses, culture, &c.; with a description of 7 fruit bearing and 2 ornamental varieties.

10. The *Apricot*—history, uses, cultivation and diseases, with a description of 16 varieties.

11. The *Baberry*—uses, culture, &c., and description of 4 varieties.

12. The *Cherry*—its history, uses, cultivation, training, gathering the fruit; with a description of the several classes, and of 37 varieties, with engraved outlines of 31 varieties.

13. The *Currant*—uses, propagation and culture; with a description of 10 fruit-bearing and several ornamental varieties.

14. The *Cranberry*—general remarks on its localities, culture, uses, &c.

15. The *Fig*—history, propagation, culture; with a description of 15 varieties.

16. The *Gooseberry*—its history, uses, propagation and cultivation; with a description of 40 sorts, esteemed by Mr. Downing as most valuable.

17. The *Grape*—its history, uses, soil adapted to its culture, propagation, cultivation under glass, with and without heat—descriptive figure of a vinery—insects and diseases peculiar to the grape—a description of 35 varieties of foreign grapes, 3 of them figured in outline: *Black Hamburgh, Royal Muscadine* and *White Muscat of Alexandria*. Also a chapter on the cultivation of the *native grapes* in the garden and vineyard—remarks on the diseases to which they are liable, and a description of 12 varieties, 5 of them figured in outline, natural size, viz: the Bland, Catawba, Elsinburgh, Isabella and Ohio.

18. The *Mulberry*.

19. The *Nut*.—Description and cultivation of the walnut, hickory nut, filbert, &c.

20. The *Plum*.—Its history, uses, propagation and culture—soil adapted to it—insects and diseases which attack it, with speculations on their causes, preventives and remedies, and description of 97 varieties, 29 of them figured in outline, natural size.

21. The *Pear*, as the author says, "the favorite fruit of modern times and modern cultivators."—Its history, uses, gathering and keeping the fruit, propagation, soil, culture, diseases; with a description of 233 varieties, 80 of them represented in outline figures, natural size.

22. The *Peach*.—Its history, uses, propagation, soil and situation—pruning, training, insects and diseases, with quite an elaborate disquisition on the yellows; in which the author seems inclined to advocate the belief that this is a "constitutional taint," existing in many American varieties of the peach, and produced in the first place by bad cultivation, instead of being, as many suppose, a "contagious disease"—to which is added, remarks on the distinctive characters of the leaves of classes, and descriptions of 79 varieties.

23. The *Nectarine*.—History, culture, &c., and description of 19 varieties.

24. The *Quince*.—History, uses, propagation soil and culture, and description of 5 varieties, 3 fruit-bearing and 2 ornamental.

25. The *Raspberry* and *Blackberry*.

26. The *Strawberry*.—History, culture, &c.—a description of 36 varieties, with figures of the two newest and best American seedlings: Hovey's and Ross's.

27. The *Musk Melon*.

28. The *Water Melon*.

29 The *Orange Family*.

30. The *Olive*.

31. The *Pomegranate*.

Then follows an essay on the "Duration of varieties of Fruit Trees," and the book closes with a very useful appendage: a key to the pronunciation of French names.

No one Tastes so Good Fruit as he who Raises Them.

This is particularly true as regards the small fruits of summer. The black mulberry, it is stated in the Encyclopædia Americana, is in perfection only a few moments, and that at the time when it can be detached from the tree by a slight shake of the branches. "All the fruit," says Dr. Alcot "but more particularly the berries, are more or less subject to the same law." The perfection of the strawberry lasts but an hour or two; and even the pea, the bean, and Indian corn, lose much of their freshness and flavor, by being plucked the day before they are used. Those who raise fruits, therefore, may pluck and eat them when they are at perfect maturity, when they are more grateful to the palate, and most conducive to health. Those who buy them, on the contrary, must buy those that are prematurely gathered, or which have passed their best state, and are in the incipient process of decay. In general, part of these objections lie against the summer fruits which are sold in the market—they are gathered before they are ripe, and they are in the progress of decay. How important is it, therefore, that the lovers of good fruit, should take care to have it in perfection by selecting and cultivating the choice varieties.

"The juices of all green fruits," says Dr. Alcot, "are different from those of ripe ones. Their acids are less wholesome than after they are changed by the action of the sun in ripening, nor does the addition of saccharine substance in preparing them, at all change their real nature. They are only concealed. The oxalic acid is still oxalic acid, cook green fruit as you will. No culinary process, I repeat, can be substituted for, or produce the effect of the solar action. The Creator, in many instances, by means of the sun, performs the most perfect culinary processes, and nature is often the best kitchen and cook.

The use of ripe fruits is admirably adapted to allay the feverish irritation of the stomach and bowels, at the seasons when they severally come to maturity; but unripe fruits, or those in the incipient stages of decay, are calculated to increase these excitements, and to generate disease. Fruits should always become ripe in their natural way, and be eaten when they are in their highest perfection.—*Albany Cultivator.*

Elevation of Agriculture as a Pursuit and a Profession.

The pursuit of agriculture is almost universally considered as merely a profession of commerce or trade, the farmer looking wholly to its pecuniary results. In a trading community, pecuniary considerations are always liable to control the judgment and predominate over every other consideration. Where the means are limited, and the farm must be cultivated as the only source of subsistence, pecuniary returns must, of course, be the main object. Where, as in England, the cultivator is not the owner of the soil, but an annual rent must be paid, and he is liable, as in most cases, to be compelled to quit his occupancy at the pleasure or the caprice of his landlord, farming must be conducted merely as a matter of business, and there is no inducement to pursue the profession as a matter of taste or sentiment. In many cases in my own country, it must, of necessity, be followed wholly as a means of support and of profit, and in some cases as a struggle for life.

But there are innumerable other cases, in which men have the power, under the most favorable circumstances, and I am most anxious they should have likewise the disposition to devote themselves to it as an elegant and liberal profession, worthy of a mind gifted even with the finest taste, and enriched by the highest cultivation. The United States present not many examples of very great wealth, at least when estimated by the standard of wealth which prevails in England, where, indeed, are to be found individual accumulations which distance all the dreams of oriental magnificence. But, on the other hand, no country upon the globe, and no condition of things since the establishment of society, ever presented more favorable opportunities than the United States for any one, by active and wholesome industry and a proper frugality, to acquire a competence, and that respectable independence, in which, with a full supply for the necessities of life, and an abundant provision for its comforts, there will be found within reach as many of the elegancies, and ornaments, and luxuries of life, as a well-disciplined and healthful state of mind can require. I have seen too frequently such beautiful examples in our country villages, and scattered over several parts of a land in many respects favored by Heaven above every other, not to be deeply impressed with a condition of life which, where its blessings are properly and gratefully appreciated, seems to leave little more on earth for a rational and reflecting, a benevolent and truly religious mind, to ask. Happy is it where its waters are not poisoned by an insatiate avarice, nor disturbed and thrown into confusion by ambition of political office or distinction, or a feverish thirst for notoriety and excitement; but in a quiet, yet not stagnant repose, they reflect everywhere the tokens of that divine goodness, which seems in such examples to have poured out its richest earthly treasures. Now, I am anxious that agriculture should occupy that place among the liberal professions to which it can be raised, and to which, from its importance, it is entitled. But this can only be done by improving the education of farmers as a class—by multiplying, hrough the means of a most liberal and extended education, the charms of the country, and the subjects of interest which would be constantly more and more developed to a cultivated and inquisitive mind; and by showing that its successful pursuit, either as a matter of business or recreation, where a moderate fortune is possessed or a moderate professional income is secured, is not incompatible with the highest improvement of taste, and even a vigorous and successful pursuit of learning; and that, where so pursued, under favorable circumstances, it affords as fair a chance of rational enjoyment and quiet usefulness, as any situation which the most lucrative trade, or the most successful political ambition, or even the highest professional eminence, can command.

But I fear, how much soever I may satisfy

the sober and reflecting minds on this point, my opinions and persuasions will scarcely be heard, and far less heeded, in that rush for wealth, for office, and for notoriety, which, like a torrent sweeping over the country, carries every movable object in its course. It seems, however, not less my duty to record my strong convictions, which the experience of a life not short has served only to confirm. I see in my own country, every where proffered to an honest industry, a wise frugality, and a wholesome self-government, the most ample rewards: I see a wide extent of rich and beautiful territory waiting the improving hand of skill and labor, to be had in many cases almost for asking, with every man free to choose where he will pitch his tent, not only without injury, but to the advantage of his neighbor: I see the means of education, of competence, and of substantial independence, held out to all who will avail themselves of them. In the midst of all this, I see thousands and thousands of young men, blest with education and fortunes adequate to supply all reasonable wants in the country, rushing into cities, exhausting their small means in the extravagancies and dissipations of fashionable life; crowding all the professions to repletion; pressing on, with vexation and disappointment heaped upon vexation and disappointment, into all the avenues of political office and distinction, and into all the bitter strifes of political controversy; forcing their way into the pursuits of trade without talents for their prosecution, and almost sure to involve themselves in bankruptcy and ruin; and, in one form and another, dragging on through life without satisfaction to themselves and without usefulness to others, and too often a ruinous burden upon those whom it is now their turn to succor and relieve. I cannot, therefore, help wishing that the pursuits of agriculture might be made attractive to such persons; and that with education, and that moderate fortune which would give them the command of the best advantages of rural life, they might find in it, as far as rational happiness and humble usfulness are concerned, that philosopher's stone which in other places they are almost sure to search for in vain.—*Coleman's Agricultural Tour, No. 3.*

Study of Botany by Ladies.

Extract of a Lecture read before the Ladies' Botanical Society, at Wilmington, Delaware, March 2, 1845. By. Dr. Wm. Darlington, of Chester, Pennsylvania:

"Of all the intellectual exercises kindly provided for us in this stage of being, few are more instructive or more agreeable to contemplative minds than the *study of nature*—or, the investigation of the history, character, relations and purposes of the material objects which a wise and beneficent Creator has placed around us; and, of the several departments of what are called the Natural Sciences, perhaps one of the most useful—certainly one of the most elegant and attractive—is that which embraces the varied products of the vegetable creation.

"The science of Botany has for its objects the most lovely of all the inanimate works of God. It treats of those beautiful forms which annually unfold themselves to our admiring gaze—which every where clothe and decorate the teeming surface of the earth, affording, directly or indirectly, the sustenance of all animals, and regaling every sense of every creature that has capacity to be gratified. It is a science peculiarly appropriate to gentle minds. Its cultivation imposes no tax upon the feelings—involves no cruelty—shocks no sensibility; all its incidents and attributes are promotive of corporeal health and pure intellectual pleasure. Why, then, should not a rational acquaintance with those interesting products which surround us on every hand and are literally strewed along our paths, why should not such a science be made an indispensable branch of female education? As a mere *accomplishment*, it is entitled to rank with any of those ornamental acquirements to which so much time is devoted. As a means of enlarging and disciplining the mind, training it to habits of correct observation and profitable reflection, the study of plants is far superior to many of the fashionable and fugitive attainments which now so generally engross the attention of young ladies. It is a pursuit, too, which carries with it its own reward. The knowledge which it affords is at once pleasing in the acquisition, and of enduring value. It is continually called for and always at command, ready to minister to the instruction and gratification of the possessor, whether in the garden, the field or the forest.

"'These studies,' said the Roman orator on another occasion, and it is even more emphatically true on this, 'These studies are the intellectual nourishment of youth, and the cheering recreation of age; they adorn prosperity, and are the solace and refuge of adversity; they are pleasant at home, and are no incumbrance abroad; they abide with us by night—go with us in all our travels, and lend additional charms to the attractions of our rural retreats.'

"Those who make only occasional visits or excursions in the country will find their pleasure greatly enhanced by an acquaintance with the plants which mainly contribute to the beauty of the scenery: but, by those whose constant residence is in the midst of the vegetable tribes, a reasonable knowledge of Botany should be regarded, not merely as an accomplishment, but, as one of the indispensable qualifications for the duties of rural life. I have often insisted that an American Farmer should blush to be ignorant of the objects of his peculiar care; and I know not why a Farmer's Wife or Daughter should be entirely excused for a like deficiency in her attainments. On the contrary, I believe it is to wives and daughters that we must look for the commencement of a thorough reformation. A competent knowledge of the character and properties of those plants which interest the gardener and the agriculturist, is unquestionably desirable for both sexes: and I sincerely believe that the most effectual method of diffusing such information will be to invoke the friendly aid and countenance of the ladies. Their salutary influence has been felt and owned in many a noble cause, and I cannot doubt their efficacy here.

"Some of my young friends, although, perhaps, assenting to the justice of these views, may yet be inclined to object, that the science of botany is so encumbered with uncouth terms, and barbarous names, as to obscure its charms, and even render it repulsive to the youthful student. I am free to admit that appearances, at a first glance, seem to warrant the objection. I have experienced all its force, and can fully appreciate its influence upon others: but I can truly add, for the encouragement of beginners, that, when the study is properly conducted and the subject comes to be rightly understood, the difficulty is rather *seeming* than *real*. It undoubtedly appears enormous to the uninitiated—just as strange objects are apt to be magnified when encountered by twilight, or viewed through a mist; but there is no ground for dismay or apprehension. The supposed obstacle will either vanish when approached, or prove itself to be an aid, rather than an impediment, in the way of the learner. It is, indeed, impossible to describe objects or to communicate definite ideas without the employment of terms and names; yet these are not science. They are but the *implements*—the mere machinery with which the mind operates, and should only be taken up or resorted to as they are wanted for use. It is worse than idle to commence by lumbering the memory with hard words, of which the student comprehends neither the meaning nor the application. Such a plan, I admit, is calculated only to dishearten and disgust. But, let him begin, where all true knowledge begins—by a practical acquaintance with *things* rather than with *names*—by observing features and examining structures, and he will soon perceive the importance of *terms* by which to designate and distinguish the objects of his attention. When the investigator of plants comes to take a discriminating view of the vegetable tribes and observes the varied, yet definite forms, and arrangement of the organs, which constitute their botanical character—so far from complaining of the burthen of names and terms, he will eagerly seek and adopt them, as indispensable aids in his progress; and he will find, moreover, that, although many appear harsh and arbitrary, the greater number are remarkably significant and appropriate. A moment's reflection will convince any of us that even in the common occurrences of life, we cannot dispense with the names, and what may be called technical terms, and that new ones are continually added to our stock, without an effort, and almost without our consciousness. When we make new acquaintances among our own kind, especially if they are agreeable, we never think of such an objection as that of having to learn or remember their *names:* and even in the minor gratifications of dress and personal comfort, we are all very expert in acquiring the nomenclature—strange though it be—of such articles as attract our notice or suit our fancy. The facility with which young ladies become familiar with the vocabulary of taste and fashion—their admirable tact in discerning, and their fluency in discussing the qualities and patterns of *Gimps* and *Ginghams*, *Gros des Indes* and *Mousselines de Laine*, satisfy me that *technicalities* have no real terrors for them; and the *language of botany* can never present any serious obstacle to their progress in the science—*provided* that they have the will and the application: and I desire no better evidence of the requisite disposition and effort than that which I have now the pleasure to witness."

To Prevent Smut in Wheat.—We have received, says the American Farmer, the annexed note from the Hon. Wm. Carmichael, whose authority with us is equal to that of any agriculturist of our State:

In the third volume of the Farmers' Register, page 743, there is an account of a series of experiments, made by M. M. de Bombasle, for preserving wheat from the smut, one of which he found entirely successful, and perhaps some benefit may be derived from an account of the advantage I have derived from its application.

Smut was brought on my farm by changing my seed wheat, and though it never extended so far as to produce very serious injury, I was very anxious to expel it: and, in the year 1843 I used the means in the article I have referred to, according to the manner therein directed. At the next harvest, I found the smut much diminished but some still remained. Last fall I used the same means, under a different application. I dissolved in a large tub eighteen pounds glauber salts in twenty-two gallons of water. The wheat was thrown into it, well washed, and so much of the solution as was not taken up was drawn off for further application; the wheat was then put into a bed of quick lime (slaked immediately before being used) on my barn floor, well stirred so as to produce adhesion to each grain, and then spread to dry.

I have lately finished threshing. I have examined the wheat, and have not detected a smut ball. This is also the experience of my overseer, and my most observant laborers.

I donot know that the germinating power would be injured if it remained unsown for many days under the lime, but to avoid the hazard, I have not permitted the wheat thus prepared to remain more than three days unsown.

My neighbor Mr. Wm. De Coursey, to whom I communicated the experiments of Mr. Bombasle, made one with common salt, by which the smut was much diminished, but some still remained. My experiment with glauber salts has resulted in entire success.

Agricultural Inconsistencies.—Prejudice and error generally go hand in hand: a man may be allowed to indulge in obstinacy for his own gratification, but when society is affected by it, the sooner a new light breaks in upon him the better. I proposed subsoiling my heavy

land for beans, so as to admit the action of frost and air abundantly. A demurrer was instantly raised by a farmer present. Oh! we always plow shallow for beans. Well, I know you do. Do you ever double-spit your gardens? Oh, certainly we do. Do you ever grow beans in your garden? To be sure, capital ones. What, and that on double dug ground? Impossible, surely. It would puzzle a conjurer to tell why a farmer always digs his garden 20 inches and plows his land only 5 inches. Docks, thistles, couch, and other strong, deep rooted weeds are not to be found in his garden. What reason can a farmer give for drilling his beans at 7 inches in his field and 27 in his garden? Does the former mode give him a larger or earlier produce? Again, a farmer will caution you against sitting in a draught, or lying in a damp bed—of course, he takes care not to do so himself, and recommends it to his friends, but pursues an entirely different plan with his cattle. They must be exposed to both, as if their sensations and physiology differed in that respect from our own. Let us keep our cattle warm, dry and well fed, and we shall seldom feel the cramp in our pockets.—*Chelmsford Chronicle.*

CRUELTY TO ANIMALS.—In Henry Colman's first Report on European Agriculture, there occurs a passage which does honor to the heart of the writer, and is worth the subscription money of the whole work. After speaking of the aquatic birds kept on the artificial lakes in the Parks of London, the protection there afforded to their lives and the consequent tameness of the birds, he continues, "Man, in general, is a great savage, and a ferocious beast of prey. He makes continual war upon many of the animals below him, not for subsistence merely, but for pleasure. His conduct towards the brute creation shows, too often, how certain he is to abuse unlimited power, and conveys a strong argument against despotic authority. Indeed, his war upon the birds merely as a matter of sport, always makes me look upon him with a degree of shuddering, and feel that a man who can find his pleasure in the wanton destruction of little birds, the most humble of all animals in their claims, the most delicate, innocent and pure in all their tastes and habits, and comparatively useless for food, puts himself beyond the pale of humanity, and could scarcely, with safety, be trusted with a child. It were worth considering always how many of our pleasures are purchased at a most bitter expense of happiness and life to others! Two or three days coursing, manly and healthful as the exercise on horseback undoubtedly is, and strongly exciting as the sport is, did not quite reconcile me to it; and the wailings and shriekings of the affrighted and dying hares in the jaws of the hounds, sounded in my ears for several days afterwards like the cries of expiring children.—*Boston Cultivator.*

CONTENTS OF THIS NUMBER.

ORIGINAL PAPERS.

SELECTIONS, EXTRACTS, &C.

The Southern Cultivator

Is published on the first of every month, at Augusta, Ga.

J. W. & W. S. JONES, PROPRIETORS.

EDITED BY JAMES CAMAK, OF ATHENS, GA.

TERMS.—ONE DOLLAR A YEAR.

1 *copy, one year*,	$1 00	25 *copies, one year*,	$20 00
6 *copies*, "	5 00	100 *copies*, "	75 00

[All subscriptions must commence with the volume.]

THE CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to Agriculture, will be inserted for ONE DOLLAR for every square of ten lines or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞ POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS, MUST BE POST PAID, and addressed to JAMES CAMAK, Athens, Georgia.

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., NOVEMBER, 1845. No. 11.

REMARKS OF JAMES A. MERIWETHER, Esq.,

Before the Agricultural Society of Putnam Co., May, 1845

[Published by request of the Society.]

The depressed price of Southern agricultural products is leading the public mind anxiously to inquire, what relief can be found from that depression? To those who inhabit the middle region of Georgia, it is a proposition particularly interesting. With a soil once productive, but now much exhausted; a country almost too poor to live in, and yet inhabited by a people unwilling or unable to abandon or remove from it; the *relief* from our general embarrassments is naturally a subject of solicitude. Past prostrations of our interests have been rapidly alleviated by a rigid economy for a few years, succeeded by remunerating prices for our labor. But, it is only justice to ourselves to declare, that the prospect of such a recurrence is very far from being probable. The increased supply of cotton beyond the demand—the opening of fresh fields to the West, and the yearly increased quantity of labor employed in them, admonish us that it is folly to hope for a return of such prices for our labor as we have before enjoyed—while we must feel this evil of low prices aggravated by the continued deterioration of our lands. Besides, we are *consumers*, and not *producers*, of many of the necessaries of life; the reduced price of our cotton will not cause a corresponding decline in *their* prices, and hence we must bear the two-fold aggravated evils of poor lands, and low prices for their products, while *we* have to pay comparatively high prices for our necessaries. Then, with exhausted lands, and almost profitless labor applied to them, what shall we do? is the universal cry.

Many can, and doubtless will, leave the "sinking ship," and find partial relief in the productiveness of the rich alluvial lands of the West; but many *do not* wish to leave, many *cannot* leave, and it is for *these* to determine the great question, how can this country be rendered even tolerable for those who are to inhabit it.

The answer to this proposition is clothed in a few words—"*live at home—diversify your pursuits—and, above all, enrich your lands.*" To ascertain the surest and best mode to attain these ends, is the object of our immediate association.

No people ever have, or ever will, permanently prosper, who rely as we have done, upon the labor of other people, for their provisions and other articles of prime necessity. No practical man can doubt for a moment the high obligation upon every community of people, erected into States, to produce within itself the breadstuffs, meats and all domestic animals employed upon the farm. The first principles of economy, both political and private, are disregarded by a people who will not recognize this obligation; and if pecuniary embarrassments should overwhelm them, it is but the operation of cause and effect, and is at no time to be regarded as any matter of surprise, only that the effect is not more confounding. It is that system of economy which tolerates such imprudence, that in its varied operations overwhelms us with ruin and prostration.

One of the subjects which I shall more particularly invite your attention to is the improvement of your lands. A prejudice has grown up in the minds of very many persons against what is called "*book-farming*;" and many valuable suggestions are disregarded, because they are said to owe their existence to such an origin. Science is disregarded because it is said to be all theory, and not practice. But is it rational to reject the lights which it affords? What is this earth but a mighty chemical compound, and how is it possible properly to appreciate and use its ingredients without a knowledge of their natures? Soils differ in their composition, and all grains in their constituents. Every man knows from his own experience that some soils suit one plant better than others—and these very men, who reject all science in agriculture as mere *humbug*, act upon this principle of adapting their crops to their lands. Now, if this be a proper course to pursue, why will they not go one step farther and learn the reason for their preferences? But no, this would be "*book-farming*."

No profitable system of husbandry can be prosecuted without a proper knowledge of the basis on which to build. The farmer should know the elementary constituents of his soil; he should know the constituents of the plants he cultivates—knowing these, he learns the ingredients wanting in his soil to grow the crop profitably, and with a proper knowledge of the constituents of each manure, he is enabled to apply that kind which will accomplish his object. This knowledge is indispensable to the farmer who seeks the improvement of his lands. Labor is often thrown away without it, which would be profitably employed with it. Some soils only require sand, others only clay to make them productive. Lime, one of the most valuable of all fertilizers, is not only rendered valueless by an improper application of it, but sometimes it renders the soil to which it is applied sterile and worthless. The secret of success then lies in a knowledge of the constituents of the soil, and the like knowledge of the constituents of the manure.

Every farmer knows full well that he cannot plant a succession of like crops upon the same land without greatly reducing the amount of the product, and the reason is obvious; each crop takes from the soil the salts necessary to its existence, and unless they are returned to it by manuring exhaustion follows, and sterility is inevitable. The true maxim is to give back to the soil annually full measure of whatever is taken from it by the crop; in fact we should give back annually *more* than we take from it; by such means we increase the crops and enrich our lands. To do this the farmer must know what has been taken away, and he must know how he can give it back. This alone can be derived from that much despised system called "*book-farming*." It is obvious that without this knowledge all efforts at restoration are controlled by accident and uncertainty; and the result must and will prove unsatisfactory and discouraging. I would not argue that it is *necessary* that every farmer should understand the whole science of agricultural chemistry in order to improve his lands, but I do contend that he should understand some of the elementary principles of it, that he may apply them to practical purposes. Hence, to obtain this knowledge—which is beyond the reach of the great masses, is the object of agricultural societies and the circulation of agricultural papers.

A few facts will illustrate the truth of what I say. In Rhode Island an analysis was made, and an estimate based upon it of the saline contents taken from one field which had been cultivated for eight years, and the result was: potash 424 lbs.; soda 131 lbs.; lime 532 lbs.; magnesia 64 lbs.; alumina 5 lbs.; silica 390 lbs.; sulphuric acid 113 lbs.; phosphoric acid 108 lbs.; and chlorine 58 lbs.

Here, then, a large quantity of salts have been withdrawn from the earth by cultivation. Nature does not restore them as rapidly as they are taken away, but by knowing them, science enables *us* to restore them, and make the land productive, which would otherwise become sterile.

We have only to look at the crop just gathered, or the one to be sown, to learn the necessary and proper manure for it. We know that wheat contains of potash 33.84 parts; lime 3.09; magnesia 13.54; phosphoric acid 49.21. If, therefore, wheat has been sown, or is to be sown, the proper manure to be applied either to restore the land or to increase the crop, is that which contains the salts mostly contained in wheat. It has been ascertained by experiment that the actual amount of earths, &c., contained in 2000 lbs of green cornstalks is about 78 lbs. In every ton of stalks there are of

Potash	lbs 3,78	Manganese	lbs 0 40
Soda	" 0,08	Silex	" 54 16
Lime	" 13,04	Sulphuric Acid	" 2 12
Magnesia	" 4 72	Phosphoric Acid	" 1.08
Alumina	" 12	Chlorine	" 0.12

With a knowledge of these facts and the further knowledge of the properties of each manure, how easy and how agreeable is the pursuit for the farmer to add increased fertility to his soil, while he draws increased crops from his lands.

But chemical science not only gives this knowledge to the farmer, but it enables him to learn the value of foods, and the most profitable use of them. He ascertains the properties of one kind to give flesh to his animals, and of another to give fat—and what particular kinds will accomplish his object the soonest.

	Flesh forming principle.	*Fat forming principle.*
Peas contain	28 parts	51 parts.
Beans "	31 "	52 "
Oats "	10½ "	68 "
Barley "	14 "	68 "
Hay "	8 "	68 "
Turnips "	1 "	9 "
Potatoes "	2 "	24½ "
Ind. Corn "	12½ "	77 "

Thus it will be seen that there is a great difference in the different kinds of food to form fat or flesh. Peas and beans give flesh; corn, oats and barley give fat.

Again, he ascertains another important fact by chemical science; the relative value of the different kinds of food for either purpose of *fat* or *flesh*.

Sixty pounds good hay from clover are equal in nutriment to 100 lbs. common hay; 281 of potatoes; 520 of wheat or bailey straw; 574 of oat straw; 642 lbs of turnips; 20 lbs. of beans; 31 lbs yellow peas; 49 lbs. wheat; 51 lbs. of rye; 54 lbs. oats, and 59 lbs. of barley.

It is by the aid of *book-farming*, that the farmer ascertains the existence of all these important facts—and without a knowledge of them, the true principles of agricultural economy can never be applied or practised.

Our Legislature some few years since seemed to be impressed with the importance of placing agricultural information in the possession of the people, and ordered a geological survey of the State; one of the objects of which was to

obtain an analysis of the soils, and the existence of the different kinds of natural fertilizers. Some ten thousand dollars were appropriated and spent, and because the benefits of the work were not realized in the shape of principal and interest compounded annually in dollars and cents, the work was abandoned, and the people have been shut out from the information which had been obtained. The cost of these surveys is trifling when compared with the actual benefits derived from them; and may I not urge this association to undertake an examination of the lands of its members? The example will doubtless be followed by others.

In the remarks I am about submitting, it is not my purpose to attempt a dissertation on the constituents of soils, and the manner in which all vegetation derives support from them. I shall advert mostly to elementary principles, on which as a basis practical operations may depend. In the first place, plants derive their chief food from the soil. In all soils there is what is called *humus*, which is the dark colored substance we see on the surface, and it is nothing more than vegetable and woody fibres in a state of decay. This is the source from which plants are said to be directly nourished, and it is regarded as the chief element of fertility. Without it, vegetation exists very imperfectly, and in the proportion in which it does exist is estimated very much the value of soils. Humus, however, is not the only constituent of soil, and it will not of itself produce and sustain vegetation. There must likewise be clay and sand in the soil.

Clay is valuable and indispensable on many accounts; it increases the fertility of the soil by the adhesion which it contracts with water, by the solid support which it affords to the roots of plants, as well as by the resistance it presents to the too great extension of their roots—by preventing the atmospheric air from coming in contact with the roots of the plants, and by attracting *oxygen*, the substance which is so necessary for the formation of carbonic acid. The properties of clay demonstrate the necessity and profit of deep plowing; and it is from a correct understanding of them, that has originated the use of the subsoil plow, one which penetrates and breaks the clay, without mixing it with the soil, and which should be used by every farmer.

An *excess* of clay is, however, injurious to plants, because in damp weather it retains the water with which it is impregnated too long, thereby preventing evaporation and draining—because in dry weather it becomes too hard—because "it forcibly attracts and incorporates with itself the nutritive juices contained in the manure bestowed upon it, and will not part with them for the support of the plant." Washed hill-sides are unproductive, because of the presence of too much clay, and the application of manure therefore does not furnish corresponding benefits. The best treatment for such barren spots is to spread a *large* quantity of sand upon them, mix the sand and clay by plowing and then the farmer will find a profitable return in the manure he may apply.

Sand, however, becomes injurious to land where it enters too largely into the composition of the soil—because it is not sufficiently retentive of moisture—because "it does not combine with the humus or decayed vegetable matter, and hardly enters into a physical union with it sufficiently strong to absorb those fertilizing particles which the atmosphere contains"—because frequent cultivation destroys its coherence, and because sandy soils being good conductors of coloric, they transmit the influences of severe heat or cold immediately at each sudden change which the temperature of the atmosphere undergoes.

These are the respective properties of clay and sand as described by the chemist Thaer. The soil in our own county does not possess an excess of sand. Clay predominates with us, and hence the inquiry which we have to make is, how shall we improve our clay hill-sides? I have already anticipated that question in part, in the prescription of sand for *galded* or worn-out spots. This is the basis on which we must rest our system of manuring.

The next question is, how shall we prepare and apply a manure which shall multiply their production? *We need the very best manure—we require the greatest quantity possible of it—and we desire to make it upon the very cheapest plan, and with the least labor and trouble.*

Here is our necessity, now how shall it be relieved? There are many valuable manures, by the application of which, our lands would be greatly improved; but whether they are all within our reach is a different matter; we cannot adopt the use of any which, in common language, "costs more than it comes to." Lime, marl, green sand, gypsum or plaster of paris, guano, charcoal, are all valuable fertilizers, and if properly applied would soon restore the fertility of our once rich soil.

Lime produces astonishing effects—but yet to be valuable the land must be manured upon which it is applied, for the heavy crops consequent upon its application are said to be the result of the earthy exhaustion of the humus so necessary for vegetation. "It acts by accelerating the decomposition of the humus, and making it soluble, and thus fit to enter the minute fibres of the roots of plants. It also deprives *sour humus* of its acidity and renders it fertilizing." On lands containing a great quantity of sour humus, the effects of lime are most beneficial. "When animal manure has been applied for some time, lime becomes a valuable manure by decomposing the particles of vegetable matter in it, and thus making them food for plants." "Repeated ameliorations of lime will soon exhaust poor and sandy soils and reduce them to absolute sterility. Each application of it exhausts more and more of the humus until it is gone; the only remedy left is to restore to the land vegetable matter." Lime would make our clay lands more valuable by rendering them more friable, but it is a manure which in middle Georgia we cannot hope to employ.

Marl is another valuable manure, and is a "natural mixture of chalk, shells, or carbonate of lime in some of its forms, with clay or sand, or both." Professor Johnson says of it, that "it renders clay lands more open and friable, and to all soils brings an addition of carbonate and generally of phosphate of lime, both of which are proved by experience to be not only very influential, but to be absolutely necessary to healthy vegetation." *Green sand* is likewise a valuable fertilizer, containing but little lime, and valuable because of the potash it contains. In New Jersey extensive experiments have been made with it, and the fact is stated to have been satisfactorily ascertained, that one bushel of green sand was equal to ten bushels of stable manure. Both these substances exist in our own county, and sufficiently so to authorize their general application, and a small sum of money spent in a geological survey would develope their localities. They are said to exist abundantly in Morgan, Green and Baldwin. Some few years since I submitted specimens of marl taken from my own well and that of Mr. Michael Dennis, in this place, to the examination of Professor Cotting, then State Geologist, both of which he informed me were very rich.

Gypsum or Plaster of Paris, and Guano, are both valuable manures; the first is said not to be availabte in the production of corn, wheat and oats—the latter is a most powerful fertilizer, and upon poor lands will produce a most astonishing effect; but its cost is too great to admit of use on our farms. An artificial guano has been manufactured, which is said to be equally valuable with the natural, and in time may be made so cheap as to admit of general use.

Charcoal is a manure which is well worth the attention of our farmers, and is within the reach of every one. It is more lasting in its effects than any other, and alike active and fertilizing. It acts by absorbing the ammonia from the atmosphere, and from all surrounding objects, and holds it thus *fixed* as food to the roots of plants as they require it. Some plants are more benefitted by it than others, yet all are promoted by it. It should be applied to wheat, oats, corn, &c. Considerable economy may be practiced in its preparation, by burning two or more kilns on the same ground, and breaking the coal to pieces on it—the portion left after raking off the large pieces will render the earth as valuable for manure as the coal itself; then spread at the rate of 20 to 50 bushels to the acre. The coal should be powdered in a trough or other vessel which will save it from loss. I have tried it upon several kinds of plants, and astonishing results have followed its application. I have discovered that the coal which had been burnt two years produced much greater effects than that of comparatively recent preparation. The wheat crop in France is said to be increased annually several millions of bushels by the use of it.

The question left for our consideration then, is, under the circumstances, what kind of manure is the cheapest, best, and most abundant for our purposes? It is farm-yard manure; and this suits all kinds of crops the best, because it is compounded of all the ingredients which constitute the different crops grown.

Johnson, in his "Farmers' Encyclopædia," says, "of all the fertilizers the most useful and most valuable to the cultivator and yet the most generally mismanaged, is farm-yard manure, which has often been described as the farmer's sheet anchor." "The manure commonly furnished by the farm-yard is compounded of a mixture of animal and vegetable substances, of the putrefying straw of various descriptions of grain mixed with the excrements and urine of cattle, horses and swine." Nothing indeed appears so simple at first sight as the collection and manufacture of this dung, and yet there are endless sources of error into which the cultivator is sure to fall if he is not vigilant in their management. Horse dung thrown up in heaps very soon ferments and heats to an excess; the centre of the heap is charred or burned to a dry white substance called fire fanged, and in this state it loses from one half to three-fourths its value."

Again, he says, "the recent manure loses weight by lying in the farm-yard. The moisture evaporates and volatile matters escape by fermentation. By the time that the straw is half rotten this loss amounts to one-fourth of the whole weight, while the bulk is diminished one-half. If allowed to lie still longer the loss increases, till at length it may approach to one-half of the whole, leaving a weight of dung little greater than that of the food and straw which have been consumed." "In the short period of 24 hours, horse dung heats and begins to suffer loss by fermentation. If left in a heap for two or three weeks scarcely seven-tenths of its original weight will remain. Hence the propriety of early removing it from the stable and of mixing it as soon as possible with some other material by which the volatile substances given off may be absorbed and saved. The cold and rotten cow or hog dung will answer well for this purpose, or soil rich in vegetable matter, or *peat* or saw dust, or powdered charcoal; with *peat* or *saw-dust*, it will form a rich compost, and to soils which contain much inert vegetable matter, it can be applied with great advantage."

In our warm climate *evaporation* and *fermentation* have to be particularly guarded against, for they readily occur, and it is difficult to prevent either, unless by mixing the stable manure with earth.

Dr. Jackson, in his address before the last Agricultural Society of Massachusetts, says, "the most common method of making a compost with peat or swamp muck is to mix *three* loads of the peat with one of dung, and to allow the whole to undergo putrefactive changes. Then, previous to spreading it on the soil, a bushel of recently slaked lime should be mixed with each load of compost. It is usual to mix the lime in the Spring 10 to 14 days before spreading the manure; the lime should be slaked until it falls into powder." Again, he says: "Peat is valuable as a basis for com-

peat, not only on account of the large proportion of vegetable matter it contains, and the saline matters in it, but also, because it retains moisture. It is also when dry a good absorber and retainer of heat, and thus serves to maintain a higher temperature in the fields during night. Chaumont also has this property, and land sprinkled with it was found, by an experiment I made ten years ago, to be of a higher temperature than that adjoining it."

The editor of the "American Farmer" says that the richest of manure may be saved upon an easy and cheap plan. "Let the farmer mix with his horse and other dung in equal portions, layer upon layer, almost any rich earth or mould, and as he does so, let him have ground plaster or pulverized charcoal, sifted over each layer in the proportion of a bushel of the first and two of the latter to every twenty loads of dung thus mixed with the earth or mould. The manure heap when thus reformed, should be covered over ten inches with earth of some kind, the whole to present a cone-like shape so as to carry off the water."

Peat should be spread in the stable to absorb the urine, which is the most valuable part of animal manure. One of the best, if not the very best, modes of making manure in our climate is to spread both leaves and peat in the stable—permit them to remain until well saturated with urine, and until the leaves have become well trodden and the dung and peat mixed; then throw into a heap, adding peat until it exceeds the dung in the proportion of three to one. By such means the *quantity* will be very greatly increased. the dung prevented from fermentation, and all the *ammonia* which would otherwise escape and be lost, would be preserved and absorbed by the peat, and the whole mass become better food for plants than the ordinary dung. If a strong smell like hartshorn should at any time arise in the stable, sprinkle powdered charcoal and it will be arrested. This *smell* is the ammonia escaping, which forms the chief food for plants. The manure heap should at all times be protected from both sun and rain; if a pit be dug into which the manure is thrown, it will be better preserved.

A great object with the farmer is to multiply in every conceivable way the quantity of manure. He cannot rely alone upon that from the stable—his cattle are a valuable source on which he can depend. Professor Johnson says, "cow-dung forms by far the largest proportion of the animal manure which in modern agriculture is at the disposal of the practical farmer. It ferments more slowly than that of the horse and the sheep. It acts more slowly, though for a longer period, when applied to the soil. By exposure to the air it undergoes a sensible loss, which in 40 days has been found to equal one-fifth of the whole solid matter which recent cow dung contains. Although, therefore, the comparative slow fermentation as well as the softness of cow-dung fits it better for treading among the straw in the open farm yard, yet the serious loss which it ultimately undergoes will satisfy the economical farmer that the more effectually he can keep it covered up, or the sooner he can gather his mixed dung and straw into heaps the greater proportion of this valuable manure will be retained for the future enriching of his fields." It is very valuable and should be saved; and instead of permitting it to be dried up by the sun, or washed away by the rains, as it now is, let leaves be spread in the cowpens, and let peat be spread likewise; the urine will thus be preserved, as well as the excrement. If the dung could be collected daily and mixed in equal portions with *peat* the quantity would be doubled, and the value improved. An additional source of supply of manure may be had by spreading leaves and peat in the hog-pen, by which the urine will be absorbed and preserved and a compost made with the dung. As a basis for all compost, *peat* is the very best—because it retains moisture to a greater extent than any other earth, and hence will suit our dry and warm seasons. Professor Johnson says of it, "to soils which are deficient in vegetable matter, it is clear that a judicious admixture of peat must prove advantageous, because it will supply some at least of those substances which are necessary to the production of a higher degree of fertility. It decays very slowly in the air, and hence its apparent effect when mixed with the soil is very small. It will not immediately prepare the land for the growth of any particular crop; but it its decay be promoted then its immediate and apparent effect upon the soil is increased, and it becomes an acknowledged fertilizing manure. The half dried peat may be mixed with from one-fourth to one-half its weight of fermenting farm-yard manure—the heap being covered with peat to prevent the escape of fertilizing vapors—or the liquid of the farm yard may be employed for the same purpose." [*Concluded in our next No.*]

The History of the Thrifty and Unthrifty.

BY A NEIGHBOR.

From the American Agricultural Almanac.

In the neighboring village hard by, there are two farmers of equal standing as regards honesty of purpose, benevolence of intention, and all the social virtues. They both mean to discharge all their duties to society, their families and friends, and it is only when we try them by their performances that we find any striking difference. But to mark their qualities more fully, and afford instruction through the successive progression of their parentage, youth and manhood, we must notice them distinctly in each.

Their Fathers.—They were both born in the village where they now reside, and of equally reputable parents. Both were farmers and respectable members of society. The same year that the father of Thrifty was sent to the General Assembly, the father of Unthrifty received the commission for the office of Justice of the Peace. There was a slight difference in their respective characters in only one particular. They were both "well to do in the world," as the phrase is: but while the elder Unthrifty had inherited all his property, a part of which he had already spent by his easy good nature and somewhat indolent habits, the father of Thrifty had been a poor boy and worked his own way in the world, and having married early in life, had brought up a large family, while the other had but this only son.

Their Mothers.—The greatest difference, however, in their parents, was in their mothers. Like her husband, Mrs. Thrifty was a poor child and an orphan, but had been "brought up" by a widowed aunt in habits of great industry, order, and economy. She was early taught to have a place for everything, and everything in its place; to waste nothing and spend no time in idleness; and when her work was done instead of sozzling away her time, playing with the kitten or her apron strings, or sauntering with Goody Tittletattle's girls, and gossiping about the young men, she devoted her leisure hours to reading useful books, or making up counterpanes, knitting stockings, and other articles that might be useful: so that when she had become one-and-twenty, she not only had her mind well informed, but had made up quite a wardrobe for herself, and had acquired so good a character that Mrs. Thrifty thought, and rightly enough too, she was a very good match as a wife. Mrs. Unthrifty, on the other hand, had been indolently and indulgently educated, and always having enough on hand, without any necessity for looking out for herself, her parents "well off," she arrived at what ought to be "years of discretion," without any particular habits of any kind; yet being a pretty, amiable girl, and withal, having a prospect of inheriting some money, Unthrifty thought himself a lucky dog in securing her as a partner for life.

Their Boyhood.—The boys went to the same district school, yet though Unthrifty was nearly two years the oldest, little Thrifty soon caught up to him in his studies, when being put in the same class, he easily got above him, and after generally stood at the head, while Unthrifty stood at the foot. This was not owing to any want of cuteness on the part of Joe, or Josey as he was generally called, for occasionally when any prize was offered that Joe wanted to obtain, he would, by a little application, get ahead of all the boys and secure the prize; while Tom, as they called young Thrifty, would study with all his might without coming within arm's length of Joe. At hunting, fishing or frolicking of any kind, which required ingenuity or skill, Joe was sure to be ahead of all his playmates. But then his habits were negligent, he was half the time late at school, his lessons given him over night not half learned when he got there, and he had very little idea of minding any of the rules; not that he was stubborn or bad tempered, but he "didn't see any use in sitting in his own seat for three hours together, and learning arithmetic, geography and grammar, neither of which would help to tree a squirrel, hole a fox, catch a trout, or bring down a turkey at a shooting match." Tom was always punctual at school, always had his lesson learnt, though he had to work hard for it, and always did as he was bid by the master, simply because his parents told him this was the only way to make a man of himself—and he believed them. Josey's parents indulged him as they indulged themselves, and let him take pretty much his own course as they had done before him, and it was universally believed had the boys swopped parents when they were babies, Joe would have been the smartest scholar of the two.

Grown Up.—The boys got to be men while they still thought they were youngsters, and before they were three-and-twenty both were married to young women in the village, somewhat after their own character.

Their Wives.—Tom's wife was the daughter of a poor, but hard-working wagon maker, and had always been accustomed to industrious habits, while the wife of Joe had received many more advantages in school, though it is said she had misimproved them; but she could do worsted embroidery, draw pretty well from a copy, and play common psalm tunes, Yankee Doodle, and contra dances on the piano.

Their Occupation.—Tom took to farming as his father had done before him, and as he had nothing to begin with, he rented a small farm which his father helped him to stock. He had of his own, a pair of oxen, a few sheep, and some tools, which a couple of years of hard service since he "came of age," had enabled him to purchase; and his wife besides had three good cows, given her by her mother, while her father gave him a good second-hand ox wagon. Tom and his wife went "right" to work. They were up by daylight in the morning, and by the time he had his "chores" done, the cows milked and turned to pasture, the oxen curried, fed and yoked, and the pigs provided for, breakfast was on the table, so that he was ready to go out to his day's work by the time Josey and his wife had "turned out of bed."

In five years after he was married and went to farming, Tom had actually got "fore-handed" enough to buy a farm near him, which was naturally very good land, but had "run down" from the shiftlessness of the former owner; for which he paid $2,000 in cash, out of his own earnings, which were pretty much all used up by the former occupant, in paying off executions and debts against him, and he had just enough left to carry him to Michigan, to begin the world at forty, when Tom began at twenty-one. A mortgage of $1,000 still due on the place, he assumed to pay to the merchant in the village who had taken it some time before in payment of all old scores, including some $200 costs which had accumulated against the debtor.

Josey had a first-rate farm, too, which had been given to him by his father, who also stocked it with all the horses, cattle, sheep and pigs Joe wanted, but Josey "some how or other," hadn't met with very "good luck," as he called it. Indeed, 'twas some time before Josey decided he would take to farming at all.

Josey's Professional Inclination.—His father and mother, before him, had baeen in good deal

of a quandary, whether their son, on whom they thought as all parents generally do, especially if they have but one, was not rather too good for farming. He used to loiter about the bar-room when his father tried the suits before him, and he had picked up a good many legal phrases from the smart young attorneys who used to spout there. He could tell what was a "cause of action," whether the "case should be brought as an action of *tort*, or an action of *trover*," or simply "as an action on the *case*." But though often thinking about it, and rather urged by his ambitious parents, he found so many hard words in looking into Blackstone, the "*Pons asinorum*" of all legal aspirants, that he concluded he would not attempt it. His friends afterwards thought it a great pity, as if he had only got into practice, the law would give him his fees, whether he rendered any service to his client or not. Other friends equally lamented he did not take hold of medicine, for which he at one time had quite an inclination, but from which he was deterred by an indolent and unsuccessful attempt at mastering the technical names of diseases and their remedies, in that horn-book of young Galens, the Dispensary; as they said, "if he only got a run of custom, he was sure to pocket his fees, as no man living could tell what kind of medicine he gives. If his patients got well in spite of the medicine, he was a first rate doctor, and if they didn't, 'twas the fault of the disease; and as for a trial for mal-practice, it must be decided by the doctors themselves, and if they gave it against him, they would be the losers, as it would unsettle confidence in the *profession*. But if he went to farming, and didn't plant and sow right, and do his harvesting at the proper time, or let his cattle die of disease or neglect, he would have to bear the loss himself, as the law didn't compel his customers, in that case, to pay him for what he didn't sell them." In short, before they were thirty, Thrifty and Unthrifty had at last got on the same platform or level, for Tom had by this time paid up for his farm, and had it well stocked, and was entirely out of debt.

Thrifty's Farming.—But the see-saw did not stop when it brought them to this position, for Tom kept going up while Josey kept going down. His father could not help him any more, as he had only enough left to carry him and his wife through the world, while Tom had the prospect of getting some money from his father's estate, who had lately died and left a snug property. But the great difference was in their own management. Thrifty's plowing was always done in the right time, his crops were in early, and they were harvested as soon as ready to cut; his manure was always carried out and spread on the ground; his orchards were well planted and grafted with the best fruits, and he soon had the choicest to sell, which being better than his neighbors, always commanded a high price, besides supplying his own family with all they could use. The orchard was indeed one of the most profitable things of his farm. His tempting ripe peaches, with bread and milk, made a luscious meal for himself and his little ones. The rich sweet apples and baking pears, when cooked without any addition of sugar or molasses, was "sauce" good enough for a king; and it is hardly going beyond the truth to say, that it saved him a barrel of pork a year, besides giving him a luxury which any one might envy. His garden was always the best, for he chose a good spot for it, manured it abundantly, had its seeds in early, and what was best of all, he usually spent a half hour in it with his hoe before the dew was off, by which he secured an early, rapid growth, and his garden made up a third of his summer's living, besides giving good vegetables through the winter. His cows were well chosen and well fed, and were another great help to his living. Besides this, his wife made butter and cheese enough to buy all the groceries, which did not come to much, as they made their own maple-sugar and molasses, and used little tea or coffee and no spirits or wine. His sheep have good fleeces and lambs. The last gave them choice mutton whenever they wanted fresh meat, and besides they occasionally sold some to the butcher, and having got a good name for fine lambs, they always brought a large price. His wife made her own stocking yarn, and home-made flannel, and put out the remainder of the wool on shares to be worked into satinets, and fulled cloth, and flannel, so that their half not only furnished what they wanted for their own use, but gave them some besides to pay their hired men. His fences were always up, and he never suffered from the depredations of his own or neighbors' cattle. His children were punctual at school, and the whole family as punctual at church. All were neat and tidy, for Mrs. Thrifty was as busy and managing within, as he was without, and as was to have been guessed, Thrifty made rapid progress in "getting on in the world."

Josey's Farming.—With Josey, or as we must now dignify him, Mr. Unthrifty, things were quite different. He was going down-hill while Thrifty was going up; yet he took it as easy as he used to do his whippings at school, and thought himself equally as little to blame now as then; in short, "it was all his luck," as he used to say.

His fences were seldom all up at the same time; and when they were repaired, which was never done till the last minute, they were just hitched together, so that the first unruly ox that came along, would tumble it over if he squinted very hard at the dwindled, stunted crops, growing on the other side. Indeed, the poverty stricken appearance of the crops more often prevented depredation than the fences themselves. He got up late, had his breakfast late, and never went out to work before he ate it. By this time the dew was off, and none of it was hoed into the ground, or moistened the grass to make the scythe cut easier. He plowed late, sowed late, planted late, and harvested late; but he had one great advantage in all this, for he had so little to gather, that it never took a great while to secure his crops; or if the storms, snow, or ice did get them at last, he always consoled himself with the idea, "that really he hadn't lost much—they were hardly worth gathering." He had a very good orchard on his farm ten years before, thanks to the owner who preceded him, but the wind had broken off some of the branches, and for want of trimming, the broken and dead limbs had rotted down to the trunks, and made the bodies quite rotten, and the fruit itself had become stunted and wormy, and didn't bear any; and the few it bore, were only fit for the hogs, which, for the want of suitable attention, matched very well with the apples. These he had procured by years of breeding, peculiar to many of the farmers. He always killed the best pigs because they were fattest, and as soon as he got one into the pen that would not fat at all, he said she would have pigs just as well as any others, and 'twas a pity to save them, as they were worth something for pork. His sheep were neglected and got the scab. He consoled himself by denouncing the whole flock as a misbegotten race, and unworthy his regard, and turned them on to the common, where the dogs and crows soon removed both sheep and scab together. His cattle became poor from short allowance and want of attention, and as misery loves company, poverty was soon followed by lice, and thinking them too degenerate for the attention of a man of his expectations, he called them a lousy, drivelling race of Pharaoh's lean kine, and traded them off for anything he could get in exchange, old muskets, fish-nets, and a trooper's second-hand ri His house was leaky, and wanted shingling, but in rainy weather he couldn'nt go out to do it, and when it was fair he didn't want it; so his wife was taken sick from damp rooms, his children had the scarlet fever, and he got a confirmed rheumatism which lasted him for life. As we have not room for any further particulars of the history of *Thrifty* and *Unthrifty*, the remair der shall be reserved for the *American Agriultural Almanac*, for 1847.

By boiling and skimming molasses you may make it nearly as good as sugar for cooking.

Analysis of Soils.

From the Massachusetts Plowman.

We copy the following from the published transactions of the New York Agricultural Society, a copy of which was recently sent us by the officers of that Institution. We are informed, in a note, that this was the last production of the lamented Willis Gaylord, who died in March, 1844.

"Ever since the revival of chemistry, and particularly since its importance in its application to agriculture became known, experiments have been making to determine the character of the soils, their power of production, and the causes of their varying fertility, by a chemical examination of their constituents. That soils varied much in their adaptation to particular plants, was a fact perfectly obvious to all; for instance, that oats would succeed well on soils where wheat could not be grown, was a fact familiar to every farmer, and it was desirable to ascertain, if possible, the reasons of this non-adaptation, so far as it existed in the soil. It was found also, that certain plants of different species, wheat and clover for example, delighted in the same soil, and in their production could be serviceable to each other; and chemical analysis was resorted to in order to determine the cause of this affinity. There certainly appeared to be externally no good reason why this difference in the character or productive qualities of these soils should exist, and the separation or reducing them to their original elements promised much in solution of these difficulties.

Sir Humphrey Davy, whose discoveries in chemistry were so extensive and brilliant, was one of the first to enter the field of agricultural chemistry, and in the importance and value of his labors can scarcely be said to have been exceeded by any of the numerous able men that have followed in the same course of investigation. New paths have indeed been struck out, new processes adopted, many errors corrected, many new and important results been obtained, and the sphere of agricultural chemistry astonishingly simplified as well as extended, yet the honor of being the pioneer in this direction of science, as well as one of the ablest that have labored in this field, belongs to the English philosopher. Chaptal, in France; Liebig and Sprengel, in Germany; Johnston, in England: and Dana, in this country, have all been successful investigators in this department of science, and Liebig and Johnston, by the extent and success of their interrogations of Nature, have given to agricultural chemistry almost the aspect of a new science.

"It was early found that the perfect analysis of soils, required a more thorough acquaintance with chemical processes, and a more extensive and costly laboratory, than could be generally expected, and that a multitude of the original elements of soils were present in such small quantities, or under such circumstances, as to show they could be scarcely essential to the success of the crops usually grown by the farmer; and their total absence in some cases or their presence in the smallest appreciable quantities, proved that such was the case. The more important original elements, however, those which the analysis of the plants themselves, as well as of the soil producing them, proved to be essential to their perfection, was found in such quantities, and so easily determined, as to render a general knowledge of the soil—that knowledge so essential to the practical farmer—of comparative easy acquisition. The processes for ordinary analysis have accordingly within a few years been much simplified and improved, so as to be within the power of almost any one who chooses to undertake the task of investigating the character of the soils he cultivates; while the more delicate processes necessary for a refined and perfect analysis are left for the laboratory of the professed chemist.

"Cultivated soils are composed of certain earths, salts and vegetable matter, and as a general rule it may be stated that in the temperate zones, and under ordinary circumstances, the

earthy part of soils does not vary far from 90 to 96 per cent. The salts are of course in small yet active quantities; and the vegetable matter ranges from half per cent. to 70 or 75. The essential earths—those on which the peculiar qualities of all soils are based—are sand, clay and lime, or the compounds formed of *silex*, *alumina* and *calcium*. There are other elements entering into combination with these, but it is on these, and the relative proportions they bear to each other in the soil, that their fertility is depending. Pure sand, clay, lime or vegetable matter, will not produce healthy plants, or indeed in most cases, any vegetation, however imperfect; it is the mixture or combination of these that constitute a fertile soil, and analysis is the method by which the nature of these combinations, and the proportion of each element is made known.

"The mixture of these elements is usually purely mechanical, and always so with the silex and the lime; but in the clays the sand and alumina is frequently chemically combined, or in such a state that mere agitation in water will not separate them. The purer kinds of pipe and plastic clay are of this nature; indeed, what is called pure clay, although composed of perhaps 60 per cent. of silex and 40 of alumina, is of this character. Where sand and alumina is mechanically mixed, it becomes loam, the name and character of which is determined by the proportion of the several elements of sand, clay and lime it contains. Professor Johnston has in part classified the soils thus formed as follows: *Pure, or pipe clay;* about 40 per cent. of alumina, and 60 of silica. No sand subsides when agitated in water. *Strong or unctuous clay;* pure clay, with from 5 to 15 per cent. of sand, which can be separated by boiling and settling. *Clay loam* contains from 15 to 30 per cent. of sand mechanically united, and which may be separated by washing. *Loamy soils* deposit from 30 to 60 per cent. of sand by mechanical washing. *Sandy soils* contain no more than 10 per cent of pure clay. *Marly soils* are those in which the lime is more than 5, but does not exceed 20 per cent. Marls are sandy, loamy, or clay marls, as these several substances preponderate in the mass. *Calcareous soils*, are those in which the lime exceeds 20 per cent., and thus becomes a prominent constituent. *Vegetable soils*, are those in which the decomposed organic matter exists in proportion of from 5 to 10 per cent., as in garden mould, or from 60 to 75 per cent., as in peat. It is also clear that these will be clayey, sandy or loamy, as these several earths may predominate in the mixture.

"It sometimes happens that the surface soil, or the part usually cultivated, is unproductive, or perhaps entirely barren, from the too great predominance of one of the principal earths, while the subsoil may be of precisely the character wanted to give it the greatest fertility. This occurs oftener on a sandy soil than any other, as on such soils there is a constant tendency to permit clay and vegetable matter to sink through the porous surface, to a more dense subsoil. Thus there are many tracts of sandy soils so light as to be unfit for cultivation, resting on subsoils that require only to be combined with the surface one, to give the proper combination for the highest degree of fertility. Such instances may be found in this country, and they will become more common as the time increases during which our soils have been under tillage. Sprengel, among the soils analyzed by him, gives instances of some wholly barren, but which contained in the surface soil from 27 to 38 per cent. of vegetable matter. Analysis showed that while these lands contained from 70 to 95 per cent. of silica, there was but 1 or 2 per cent. of alumina, and a mere trace of lime, and thus the cause was shown at once why they were unproductive. On the contrary, the subsoil in these cases was rich in the earths and salts most wanted, and had it been raised and mixed with the surface soil, abounding as that did in humus or decayed organic matter, a soil of the most fertile description would have been the result. There is scarcely an instance of barrenness in soils, in which an analysis, such as may be made by any one, will not point out the evil, and thus lead to the best means of remedying it."

The Peach Trade.

From the Boston Cultivator.

A DAY AT THE REYBOLDS' IN PEACH HARVEST.—Desirous of affording our readers the means of forming some idea of the magnitude and importance of the Peach business of Delaware, we lay before them the details of "A day spent at the Reybolds' in Peach harvest."

We took passage from Philadelphia by the steamer Pioneer at Arch-street Wharf, at 7 o'clock on the morning of the 29th August, Reybolds' wharf adjoining being full to overflowing with his empty baskets in transitu; passing the steamer Napoleon, which had arrived at the railroad wharf on the Camden shore, and was discharging her lading of 3000 baskets of Reybold peaches for the New York market. During the passage to Delaware City we were continually passing boats of different descriptions loaded with peaches for the Philadelphia market, reaching the wharf at 11 o'clock, 40 miles below Philadelphia, where it was with difficulty that we could pass along it, for the rows of baskets of Reybolds' peaches, three tiers in height, and extending about one hundred yards in length, flanked with carriages, from the six ox and six mule wagons, counting their 125 baskets each, to the single horse cart or Dearborn, with its score or two awaiting their turn for unloading; reloading with empty baskets and driving furiously back for more—a scene which bade defiance to imagination.

Here we found the Reybolds loading a sloop which departed for Philadelphia with 1230 baskets, only to make room for the Cohansey steamer, on board which were placed 1000 baskets more; and then they began to prepare the evening's loading for the Napoleon, that had returned from Philadelphia during the day, on which were put 1700 baskets from the orchards of Messrs. John, Philip, jr., William and Barney Reybold, when she proceeded to the wharf of Maj Reybold, which is situated in the midst of his orchards, to complete her loading, another 1490 baskets, starting for Philadelphia, so as to be again in the market before daylight next morning, with a total of 3190 baskets.

The details of this day's shipment, therefore, are as follows:

On board the sloop	1,230
On the steamer Cohansey	1,000
On the steamer Napoleon	3,190
Total baskets	5,420

from the Reybold peach orchards only. These all reached their destination before daylight next morning, consigned to Mr. Anthony Reybold, by whom they were disposed of before 11 o'clock, at from 16 to 31 cents per basket, containing about 3½ pecks each.

From the books of Maj. Reybold and his sons were ascertained the quantity of peaches sent to market to the 29th August, inclusive, viz:

Maj. R. from his Maryland and Delaware orchards	31,145
John Reybold	13,300
Philip Reybold, jr.	6,000
William Reybold	5,699
Barney Reybold	7,200
Total number of baskets	63,334
No. of baskets employed for transit	40 to 50,000
No. of acres of orcharding	1,090
No. of trees planted in orchards	117,720

Business detaining us in that part of the country, we returned to Delaware City on the 31st, and found the Reybolds loading two large steamboats at the wharf—the "Napoleon" for Philadelphia, and the "Mutual Safety" for New York direct by sea; the latter of 700 tons burden, leaving with 3581 baskets on board, the former, completing the shipment for that day, a total of 4075 baskets, having taken the day before her usual loading of near 3000. Here we saw three steamers loading with peaches at the same time, while the empty return baskets had numbered 16,000 within the last 24 hours. Major Reybold has it in contemplation to start a large steamer with peaches direct to Boston! Success attend him!

In conclusion we would add, Mr. Philip Reybold, jr., is extensively engaged in the nursery business, more particularly in the raising of peach trees; of which he has from 60 to 80,000, 5 feet high and 2½ inches in circumference from the seed the present season; and from the facilities which he enjoys, as well as the peculiar care and attention employed, those requiring the very finest varieties, so as to form successional orchards, may depend upon a supply of trees true to character and of "most magnificent proportions." It is worthy of remark, the largest peach ever raised in England by the most careful culture measured 12 inches in circumference, while in the orchards of the Reybolds' the present year, one has been found to measure 11½ inches in circumference, and hundreds from 10 to 11, in the open ground and the largest crop, perhaps on record—the third in succession.

At the conclusion of the harvest we will endeavor to present our readers with the sum total of peaches sent to market from Newcastle the present season. JAMES PEDDER.

Philadelphia, Sept. 1, 1845.

P. S. Philip Reybold's address is St. Georges, Delaware.

The Apple Trade.

From Hovey's Magazine of Horticulture.

PROGRESS OF HORTICULTURE IN INDIANA.—The Horticultural Society's Fair is held annually, on the 4th and 5th of October. Experience has shown that it should be earlier; for, although a better assortment of late fruits, in which, hitherto, we have chiefly excelled, is secured, it is at the expense of small fruits and flowers. The floral exhibition was meagre, the frost having already visited and despoiled our gardens. The chief attraction, as, in an agricultural community, it must long continue to be, was the exhibition of fruit. My recollection of New England fruits, after an absence of more than ten years, is not distinct; but my impression is, that so fine a collection of fruits could scarcely be shown there. The luxuriance of the peach, the plum, the pear and the apple, is such, in this region, as to afford the most perfect possible specimens. The vigor of fruit trees in such a soil and under a heaven so congenial, produces fruits which are very large without being coarse-fleshed, the flavor concentrated, and the color very high. It is the constant remark of emigrants from the east, that our apples surpass those to which they have been accustomed. Many fruits which I remember in Connecticut as light colored, appear with us almost refulgent. All summer and early fall apples were gone before our exhibition; but between seventy and a hundred varieties of winter apples were exhibited. We never expect to see finer. Our most popular winter apples are: Yellow Bellflower, White Bellflower, [called *Detroit* by the gentlemen of Cincinnati Horticultural Society, but for reasons which are not satisfactory to my mind. What has become of the White Bellflower of *Coxe*, if this is not it?] Newtown Spitzenberg, exceedingly fine with us; Canfield, Jennetin or Neverfail, escaping Spring frosts by late blossoming, very hardy, a great bearer every year; the fruit comes into eating in February, is tender, juicy, mild and sprightly, and preferred with us to the Green Newtown pippin—keeping full as well, bearing better, the pulp much more *manageable* in the mouth, and the apple has the peculiar property of bearing frosts, and even freezing, without material injury; Green Newton pippin; Michael Henry Pippin, (very fine;) Pryor's Red, in flavor resembling the New England Seek-no-further, Golden russet, the prince of small apples, and resembling a fine butter-pear more nearly than any apple in our orchards—an

enormous bearer; some limbs exhibited were clustered with fruit, more like bunches of grapes than apples; Milam, favorite early winter; Rambo, the same. But the apple most universally cultivated is the Vandevere pippin, only a second or third rate table apple, but having other qualities which quite ravish the hearts of our farmers. The tree is remarkably vigorous and healthy; it almost never fails in a crop; when all others *miss*, the Vandevere pippin *hits*; the fruit, which is very large and comely, is a late winter fruit, yet swells so quickly as to be the first and best summer cooking apple. If its flesh—which is coarse—were fine, and its (too sharp) flavor equalled that of the Golden russet, it would stand without a rival, or near neighbor, at the very head of the list of winter apples. As it is, it is a *first-rate* tree, bearing a *second-rate* apple. A hybrid between it and the Golden russet, or Newtown Spitzenberg, appropriating the virtues of both, would leave little more to be hoped for or wished. The *Baldwin* has never come up to its eastern reputation with us; the Rhode Island Greening is eaten for the sake of "auld lang syne;" the Roxbury russet is not yet in bearing—instead of it, several false varieties have been presented at our exhibitions. All the classic apples of your orchards are planted here, but are yet on probation.

Nothing can exhibit better the folly of trusting to *seedling* orchards for fruit for a main supply, than our experience in this matter. The early settlers could not bring trees from Kentucky, Virginia or Pennsylvania, and, as the next resort, brought and planted seeds of popular apples. A later population found no nurseries to supply the awakening demand for fruit trees, and resorted also to planting seed. That which at first sprang from necessity has been continued from habit, and from an erroneous opinion that seedling fruit was better than grafted. An immense number of seedling trees are found in our State. Since the Indiana Horticultural Society began to collect specimens of these, more than one hundred and fifty varieties have been sent up for inspection. Our rule is to reject every apple which—the habits of the tree and the qualification of its fruit being considered—has a superior or equal already in cultivation. Of all the number presented, not six have vindicated their claims to a name or a place, and not more than *three* will probably be known ten years hence. While, then, we encourage cultivators to raise seedlings experimentally, it is the clearest folly to reject the established varieties and trust to inferior seedling orchards. From facts which I have collected, there have been collected during the past year, in this State, at least one hundred thousand apple trees. Every year the demand increases. It is supposed that the next year will surpass this by at least twenty-five thousand.

In connection with apple orchards, our farmers are increasingly zealous in pear cultivation. We are fortunate in having secured to our nurseries not only the most approved old varieties, but the choicest new pears of British, Continental or American origin. A few years ago to each one hundred apple trees, our nurseries sold, perhaps, two pear trees; now they sell at least twenty to a hundred. Very large pear *orchards* are established, and in some instances are now beginning to bear. I purchased William's Bon Chretien in our market last fall for 75 cents the bushel. This pear, with the St. Michael's, Beurre Diel, Beurre d'Aremberg, Passe Colmar, Duchesse d'Angouleme, Seckel and Marie Louise, are the most widely diffused, and all of them regularly at our exhibitions. Every year enables us to test other varieties. The Passe Colmar and Beurre d'Aremberg have done exceedingly well—a branch of the latter, about eighteen inches in length, was exhibited at our Fair, bearing over twenty pears, none of which were smaller than a turkey's egg. The demand for pear trees this year, has been such that our nurseries have not been able to answer it, and they are swept almost entirely clean. I may as well mention here that, besides many more neighborhood nurseries, there are in this State eighteen which are large and skilfully conducted.

The extraordinary cheapness of trees favors their general cultivation. Apple trees, not under ten feet high, and finely grown, sell at 10, and pears at 20 cents, and in some nurseries, apples may be had at 6 cents. This price, it should be recollected, is in a community where corn brings from 12 to 20 cents only, a bushel; wheat sells from 45 to 50; hay at $5 the ton. During the season of '43 and '44, apples of the finest sorts—Jennetin, Green Newtown pippin, &c.—sold at my door, as late as April, for 25 cents a bushel, and dull at that. This winter they command 37 cents. Attention is increasingly turned to the cultivation of apples for exportation. Our inland orchards will soon find an outlet, both to the Ohio river by railroad, and the Lakes by canal. The effects of such a deluge of fruit is worthy of some speculation. It will diminish the price but increase the *profit* of fruit. An analogous case is seen in the penny-postage system of England. Fruit will become more generally and largely an article, not of luxury, but of daily and ordinary diet. It will find its way down to the poorest table, and the *quantity* consumed will make up in profit to the dealer what is lost in lessening the price. A few years and the apple crop will be a matter of reckoning by farmers and speculators, just as is now the potato crop, the wheat crop, the pork, &c. Nor will it create a home market alone. By care it may be exported with such facility that the world will receive it as a part of its diet. It will, in this respect, follow the history of grains and edible roots, and from a local and limited use, the apple and the pear will become articles of universal demand. The reasons of such an opinion are few and simple. It is a fruit always palatable, and as such, will be welcome to mankind, whatever their tastes, if it can be brought within their reach. The Western States will, before many years, be *forested* with orchards. The fruit bears exportation kindly. Thus there will be a *supply*; a possibility of distributing it by commerce, to meet the taste already existing.—These views may seem fanciful—may prove so; but they are analogical. Nor, if I inherit my three-score years and ten, do I expect to die until the apple crop of the United States shall surpass the potato crop in value, both for man and beast. It has the double quality of palatableness, raw or cooked—it is a *permanent* crop, not requiring annual planting, and it produces more bushels to the acre than corn, wheat, or, on an average, than potatoes. The calculations may be made, allowing an average of fifteen bushels to a tree. The same reasoning is true of the pear—it and the apple are to hold a place yet as universal eatables—a *fruit-grain* not known in their past history. If not another tree should be set in this county, (Marion county,) in ten years the annual crop of apples will be 200,000 bushels. But Wayne county has double our number of trees—suppose, however, the 90 counties of Indiana to have only 25 trees to a quarter section of land, i e., to each 160 acres, the crop of 15 bushels to a tree, would be nearly two millions.

The past year has greatly increased the cultivation of small fruits in the State. Strawberries are found in almost every garden, and of select sorts. None among them all is more popular, or more deservedly so, than Hovey's Seedling. We have a native white strawberry removed from our meadows to our gardens, which produces fruit of superior fragrance and flavor. The crop is not large, but continues gradually ripening for many weeks. The blackberry is introduced to the garden among us. The fruit sells at our market for three to five cents—profit is not therefore the motive for cultivating it, but improvement. I have a *white* variety. Assorted gooseberries and the new raspberries, Franconia and Fastolff, are finding their way into our gardens. The Antwerps we have long had in abundance. If next spring I can produce rhubarb weighing two pounds to the stalk, shall I have surpassed you? I have a *seedling* which last year, without good cultivation, produced petioles weighing from eighteen to twenty ounces. My wrist is not very delicate, and yet it is much smaller in girth than they were.

In no department is there more decided advance among our citizens than in floriculture. In all our rising towns, yards and gardens are to be found choicely stocked. All hardy bulbs are now sought after. Ornamental shrubs are taken from our forests or imported from abroad in great variety. Altheas, rose acacia, jessamine, calycanthus, snowberry, sumach, syringas, spicewood, sheperdia, dogwood, redwood, and other hardy shrubs abound. The rose is an especial favorite. The Bengal, Tea and Noisettes, bear our winters in the open garden with but slight protection. The Bourbon and Remontantes will, however, drive out old and ordinary varieties. The gardens of this town would afford about sixty varieties of roses, which would be reckoned first rate in Boston or Philadelphia.

While New England suffered under a season of drought, on this side of the mountains the season was uncommonly fine—scarcely a week elapsed without copious showers, and gardens remained moist the whole season. Fruits ripened from two to three weeks earlier than usual. In consequence of this, winter fruits are rapidly decaying. To-day is Christmas—the weather is spring-like—no snow—the thermometer this morning 40°. My Noisettes retain their terminal leaves green; and in the southward-looking dells of the woods grasses and herbs are yet of a vivid green. Birds are still here—three this morning were singing on the trees in my yard. There are some curious facts in the early history of horticulture in this region, which I meant to have included in this communication, but insensibly I have, I fear, already prolonged it beyond your convenience.

H. W. BEECHER.

Indianapolis, Dec, 25th, 1844.

Swiney, or Disease or Strain of Shoulder.

From the American Agriculturist.

This is an affection not uncommon, but yet little understood. If of recent occurrence it will be seen that the shoulder is *swelled*; if of long standing, that the shoulder is *diminished* in *size*, the muscles having shrunk away. The shoulder is frequently shrunk when there is no disease in it. This shrinking arises from disuse of the muscles. To retain its full volume a muscle must have constant action. Now, disuse of the muscles of the shoulder may arise from two causes: 1st, lameness of the foot or leg; 2nd, lameness of the shoulder. If it arise from the foot no treatment is necessary for the shoulder. It may be easily known if it proceeds from the foot. In such case the horse, when he moves, lifts his *foot clear from the ground*; and when he points his foot forward he places it flat on the ground. If the injury be in the shoulder, when he moves he *drags the toe of the foot along the ground*, seemingly unable to lift it clear; when he points his foot out, his *toe* only rests on the ground, not the sole of the foot. If the injury is in the shoulder the horse reluctantly turns his head towards the opposite shoulder, as this strains the muscles; but he will willingly turn his head toward the lame shoulder, as this relaxes the muscles.

The common causes of shrinking or swiney of the shoulder, when it arises from the foot or injury to the leg below the shoulder, are all the diseases of the foot and leg, which continue long enough to occasion such a disease of the muscles of the shoulder as to occasion their shrinking. Such diseases are foot founder, contraction of the foot, strain of the navicular joint, ring-bone, pumiced foot, sand crack, quittor, gravel, any separation of the foot, in short, any of the various diseases of the foot which induce the horse to favor it, and thus use as little as possible the whole leg and shoulder.

The shrinking of the shoulder, where it arises

AVERAGE FOR THE YEAR.—*Barometer*, at sunrise, 29·38; 3 o'clock, P. M. 29·37—*Thermometer*, sunrise, 57; 3 P. M. 75—*Total Rain*, inches, 12·85.

* NOTE.—Course and strength of wind, from 10 to 0—0 being least and 10 the strongest. In clearness of sky, 0 represents most cloudy, and 10 perfect clearness.

from an injury in the shoulder itself, has but one ordinary cause, viz: a strain of the shoulder. When there is s rain of the shoulder it is known at once. Within a few hours after its occurrence the shoulder is swelled, perhaps in its whole length, but generally at the lower end. The strain lies almost always in muscles which attach the shoulder-blade to the body; yet the swelling is on the outside; but this arises from sympathy.

When the horse is observed to be lame, and it cannot at once be determined where the lameness is, let him be walked, and if *he drag his toe*, it is in the shoulder. Let the shoulder be examined in front; if the affection be of long standing, the shoulder will be seen to be less than the other. If on feeling it, it be found to be free of heat, there will be no fever. The disease is then chronic. If, however, the shoulder be enlarged, it will be found, on feeling, to be hot —the injury is then recent and inflammatory. Where the disease is in the shoulder and is chronic, it has gone through the inflammatory stage, and is of some considerable standing. The chronic state is rarely cured. It is not unlike rheumatism. For the *chronic state* the best remedy is active *blistering*. This will rouse the vessels to activity. It may be necessary to blister repeatedly, and exercise should accompany the blistering, with good grooming and general care. Let the exercise commence as soon as the blister begins to diminish its discharge. This treatment continued judiciously and energetically for some time may cure *chronic* disease of the shoulder. When the strain is recent and inflammation exists, the horse should be bled from the neck and from the plate vein on the inside of the leg, as near the body as possible. Rest, cooling physic, both purgative and sedentary, should be given—*no blistering* should be allowed. Embrocations of a cooling nature should be applied. No *stimulants* should be applied externally, or given. They but add to the inflammation. When the inflammation is subdued and the shoulder has fallen back to its natural size, the horse needs nothing but rest with gentle exercise. Let him be turned out, if in the summer, to grass; in the winter, into a small yard in good weather, and a stable at night in bad weather. It will take him some time to get over the effects and be fit for work again.

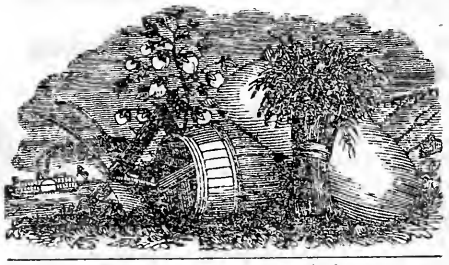
When the shoulder is shrunk or swineyed from lameness in the foot or leg, below the shouldre, no attention should be paid to the shoulder. When both feet or legs are diseased so that the horse seeks to relieve each alternately from pressure, both shoulders will be swineyed; they will be both shrunk, and the breast in front will be diminished and fall in. Treatment in these cases is to be addressed to the place of disease. If in the feet, cure them; if in the legs, cure them. Some diseases in the feet cannot be cured, and, of course, if there be swiney from such cause it cannot be removed. When the feet and legs are cured, and the horse recovers thereby his wonted action, the muscles of the shoulder will by exercise, recover their former size, and the swiney be gone.

Among the ignorant there is a variety of remedies for the swiney, as pegging (that is thrusting a knife in the shoulder and blowing in stimulating powders,) swimming, setons, &c. A recent writer in the Southern Cultivator says, "introduce the small blade of a common pocket knife (the point of which must be sharp,) into the thinnest part of the shoulder, which will be near the upper margin of the shoulder-blade, holding the knife as you would a pen when writing, and scratch up the membrane that covers the bone for a space the size of a silver dollar; the knife may be then withdrawn. The knife may then be introduced in one or two places below the first, and used in the same way, and the operation is over." Now, if the disease be in the shoulder, this method can only cure by rousing the vessels to action. Blistering will do this better, and is more humane and less dangerous. Wounded membranes frequently produce fatal inflammation. Blistering is never dangerous in chronic affections, and therefore is preferable on that score, and by general action does far better. It is done within two days. Scraping the membrane cannot be through its operation short of weeks. A. STEVENS.

Buffalo, January, 1845.

EDUCATION.—The following gives the state of education in the United States, in 1840. It shows the number of white persons in each State above the age of twenty-one, who can neither read nor write:

No. 1. Connecticut—1 in 311.
No. 2. New Hampshire—1 in 159.
No. 3. Massachusetts—1 in 91.
No. 4. Maine—1 in 72,
No. 5. Vermont—1 in 63.
No. 6. Michigan—1 in 44.
No. 7. New York and New Jersey—1 in 26.
No. 8. Pennsylvania—1 in 22.
No. 9. Ohio—1 in 18.
No. 10. Iowa—1 in 17.
No. 11. Louisiana—1 in 16.
No. 12. District of Columbia—1 in 15.
No. 13. Maryland and Wisconsin—1 in 13.
No. 14. Indiana and Mississippi—1 in 10.
No. 15. Florida—1 in 8.
No. 16. Illinois, Arkansas and Missouri—1 in 7.
No. 17. Delaware, Virginia, South Carolina, Alabama and Kentucky—1 in 6.
No. 18. Georgia—1 in 5.
No. 19. North Carolina and Tennessee—1 in 4.



The Southern Cultivator.

AUGUSTA, GA.

VOL. III., NO. 11..NOVEMBER, 1845.

Our Fourth Volume.

The publishers avail themselves of the present number to announce to the PATRONS and FRIENDS of the "SOUTHERN CULTIVATOR," that they will in a few days issue a Prospectus for the FOURTH VOLUME, which will be extensively circulated, and they can but indulge the hope that every *friend* of the work will make some effort to extend its circulation.

The Peach and Apple Trade.

The reader will notice two articles in this number of the CULTIVATOR, which will perhaps occasion some wonder—we allude to the articles on the peach and apple trade.

In addition to the information contained in Mr. PEDDER's article, we have learnt that from the orchard of the REYBOLDS there were sold, up to 29th August, 63,234 baskets of peaches; and up to 8th September, the number had reached to 75,000. The basket contains about half a bushel; and at the first of the season sells for something like three dollars; when the crop is fully ripe, the price falls to about 75 cents. The orchards of the REYBOLDS are said to contain 1090 acres, and 117,720 trees.

RIDGEWAY's orchard in the same neighborhood is a very productive one. It comprises only about 200 acres. In 1839, from 170 acres there were gathered as much as 18,000 bushels of ripe fruit; and about 25 acres had not come into full bearing.

The *Tribune* estimates the whole number of baskets of peaches sold in the city of New York last summer, during the 40 days of the peach season, at 12,000 baskets per day, making 480,000 baskets in all; which, at the average price, would make about three-fourths of a million of dollars paid by the people of New York for peaches in a single year. Mr. DOWNING may say with perfect safety, as he does in the preface to his "Fruits and Fruit Trees of America," that there are more peaches offered for sale in the markets of New York annually, than are raised in all France. And such peaches—so beautiful and so luscious! The best orange is hardly superior to some of the best sorts of Jersey Peaches. We have neglected the peach, as we have nearly every thing else but cotton, in the South, until our best sorts have become so poor, as to be a little worse even than Jeremiah's figs:—for though, according to Peter Pindar's account of these said figs, the bad were not fit for pigs, yet the good were very good. Peter couldn't say as much for our Southern peaches, if he had ever tasted some of the best Jersey varieties, such as the Grosse Mignonne, Red Cheek Malacoton, Early Admirable, or Early Crawford. The business in New Orleans last summer, shows how very inferior our peaches have been allowed to become, through sheer neglect; for there is no tree that repays so generously the care bestowed upon it. Even in that city the sales were only about 1,100 bbls. and 1000 boxes of peaches, nectarines, pears and quinces, amounting to about $4,200. This is mainly attributable, Mr. RUFF says, to the bad quality of the fruit; but the demand, he is confident, will keep pace with the production of *good* fruit.

Why can't the people along the lines of Railroad leading to Charleston, Columbia, Savannah, Augusta, Macon and Montgomery, use some of their poor sandy land that is good for nothing else, in raising good peaches for the supply of the markets of those cities? They have every thing to encourage them, as the facts we have stated clearly show. But unless they get the improved sorts, and then take care to cultivate them properly, they had better let it alone.

The other article is about the Apple Trade. Though it relates chiefly to the state of Horticulture in Indiana, we have copied the whole of it, because, coming from the pen of the Rev. Mr. BEECHER, Editor of the *Indiana Farmer*, it is, of necessity, very interesting. But our principal object is, to introduce to our readers the speculations of Mr. B., on the figure the apple is destined to make hereafter in the world, both as an article of food and of commerce. Do you think the estimate of Mr. B., an extravagant one? Remember there is a strong array of facts against you, some of which we will mention. The crop in the West is a short one this year, owing to late spring frosts. To supply the deficiences, there had been shipped, up to the first of October, from Oswego alone, 5000 barrels of apples for Ohio and Michigan. From other lake ports we have not heard. Mr. DOWNING says, nearly a quarter of a million of fruit trees have been planted in one year, in one of the newest Western States. You see these people believe in Mr. BEECHER. Mr. PELL, of Westchester, New York, has an apple orchard of twenty thousand trees. He sells his apples in New York at six dollars per barrel. The best, however, he sends to England, where they command twenty-one dollars per barrel. The nobility, and the wealthy people, bought them last year at a guinea a dozen, or about 45 cents a piece. Last year he sold 9000 barrels. This year he has already sold between 3000 and 4000 barrels. Scotch physicians prescribe American apples for dyspepsia. It is no unusual thing for an English lady to have on her table at a party, fruit which cost from £400 to £500. A dinner was given by an English nobleman some years ago, for which the fruit alone cost £6000. Invariably, where English and American apples are exposed for sale together in the London fruit shops, the American are preferred at double the price of the English.

With such a demand for fruit, both at home and abroad—with the means of supplying it afforded by American soil and climate and industry and energy and love of gain, Mr. BEECHER can't be far wrong in his anticipations.

What is all this to us of the South?—you ask. Is it not something to know that cotton and rice and sugar are not the only things whereby the pocket may be relieved from collapse—that riches may come of raising even peaches and apples? Moreover, if for want of direct and regular steamships between Savannah and Charleston and Europe, we may not furnish apples for English noblemen to eat, at 45 cents a piece, ought we not at least, to supply our own Southern cities, instead of allowing them to depend on supplies from abroad? The world may be defied to show better apples than the mountain region of the Southern States produces, with proper care. Some say the apple with which Eve was tempted grew here. About that we say nothing, because we don't know how it was. But we do know that the people of our mountain region love money just about as much as most other people; that they have about as much need of it; and that their apples will bring money about as surely as any thing they raise for market. It will be their own fault, if in a few years, a Yankee apple shall be seen in any of our Southern cities.

Lime.

We are not quite sure that Mr. BROWN intended his letter for publication. Not seeing how we could so well forward his ends as by publishing it, we have, Jackson-like, taken the responsibility of doing so. His purposes are now known to our planters, as well as to those who have the management of our railroads. We wish him all the success he can desire; and beg leave to add, that on the subject of transporting lime on railroads, to be used for agricultural purposes, we have never had but one opinion; and that is, that it ought to be transported at the very lowest possible rates. We are pretty sure there will be scarcely any demand for it at the prices stated in Mr. B's postscript. And even at such rates as it might be afforded at, were the freight reduced, it will take a great deal of persuasion to bring it into use. But we don't despair. As the waters wear the stones, so will the frequent repetition of our advice, and the example of others, we hope, wear away in time, the prejudice that exists against every thing that proposes to change the old system of husbandry in the South.

Sugar Cane.

The fact stated by "*Quisque*" in this number of the CULTIVATOR, if there be no mistake about it, is a very curious one. We can find nothing in the writings of vegetable physiologists, or in the recorded experience of practical gardeners, to throw any light on the subject. LINDLEY, KNIGHT, HERBERT, indeed every one, refers to the simple process of dusting the stigma of one plant with the pollen of another, as the only way in which either cross breeds or hybrids are produced: and that the act of fertilization consists in the emission, by the pollen, of certain tubes of microscopical tenuity, which pass down the style, and eventually reach the young seed, with which they come in contact; and, unless this contact takes place, fertilization misses.

Now the sugar cane does not blossom and bear seed, we believe, anywhere but in tropical climates. It is quite certain, therefore, that none of the established principles, of either muling or crossing, can be applied to explain the production of the new variety of cane mentioned by our correspondent. The case is, however, not without parallel. Something of the same kind came under our own observation a few years ago, occurring in our own grounds. The sweet potato does not bear seed, and but seldom produces even blossoms in temperate climates. On one occasion, we had the varieties known as the yam, and the Red Bermuda, growing in contiguous rows. In gathering the crop, we found one of the yams

true to its kind in all respects, except a stripe from end to end of about one-fourth its circumference, which was beyond all question of the Red Bermuda. The yams had blossomed in previous years, but the Bermuda never had with us. How did this mixture of the two kinds occur?

The Maine Farmer.

The editor of the *Maine Farmer*, in his paper of October 9th, copies from the CULTIVATOR of September, our commentaries on his articles therein inserted, and replies as follows:

In relation to the neglect of the South in the disbursement of the public money, Dr. HOLMES answers—

(1.) Alas, friend Camak, the answer is too obvious. We are, both of us, precluded by the *neutral* stand which agricultural papers ought to take, from going into these subjects in detail, because it would of necessity expose the "rottenness *in Denmark*"—the utter and shameless rotten-heartedness of the political leaders of each and every party. It would carry us into the very depths of the slimy and miry slough of party tactics, and party discipline. We may not do this: but we may say, or shall at any rate say, that the day of pure political principle and action has gone by. Men are not now as in the days of Washington, and Henry, and Franklin, and Sherman, chosen to high offices because they loved their country and their *whole country;* but because they will subserve some selfish purposes of this or that clique. The practice of politics has become a game, and he is most successful who is most skillful in the shuffle, cut and deal of the political cards. A government ought to distribute its favors and requirements equally—justly and without partiality all over this territory. The meanest and most humble spot should not be neglected—the poorest citizen should be cherished and protected. That it is not so, we grieve to say is the case, and we see not how either of us can help it, any further than our individual influence and exertions for truth and justice can go. If mere complaining were the order of the day, every section of the Union could find veritable cases enough for stock to work upon."

About the six per cent. and the one mill per cent. Treasury notes:

(2) "This is new to us, and we really do not see what right those who did the deed had so to do. It is customary for governments, both State and national, to issue scrip at different times, bearing different rates of interest; but that scrip should be issued with reference to any particular section of the Union is new doctrine."

To the last paragraph of our article, he responds thus:

(3.) "If we felt aggrieved, as our friend Camak appears to be, we should probably utter the *tallest thunder* we could muster. At the same time we should think it a duty to "be patient, be advised." We should endeavor, while we labored hard to remove any injustice which bore heavily upon our own particular section, to let reason take a calm survey of the whole ground, from "Maine to Georgia," and strive to so balance matters that the prosperity of all should be promoted, and the rights of none infringed. We live together, as a nation, bound by a chain of mutual concessions. The union depends upon such bonds, and while each section, from natural locality, must vary more or less in its interests, they should cheerfully yield a little, each to each, and by thus yielding, become strong in their mutual bonds. Leaving subjects of a more public political character, permit us, friend Camak, to both encourage and sympathize with you in your efforts to rouse up the good people of the South to a sense of their own interest, and to urge upon them the duty and necessity of well directed and well concerted action, in agricultural, as well as other reforms. We have had some experience for the last fifteen years in this business; for in our own section, as well as yours, there is much to reprove and to censure. Idleness is the besetting sin of man the world over, and all the concomitant evils of apathy and supineness bring with them the results of comfortless want wherever they prevail, whether it be North or South, East or West. On the contrary, industry, frugality and perseverance, will finally surmount both national and political obstacles—clothe the old fields with verdure, and make the wilderness blossom like a rose. While we find ourselves laboring under many difficulties, and sometimes ready to become sick and faint amid the battle with prejudice, obstinacy and ignorance, we would, nevertheless, bid you God speed in your own endeavors to bring back the flourishing and palmy days of the South, and hope, ere you die, you will see your labors crowned with a success far beyond your most sanguine hopes; and not only your own, but every State in the Union blessed with prosperity and filled with a virtuous, contented and happy people."

Hill-Side Ditching.

Hard as it is to change old habits, and much as our people may dislike to abandon their slovenly and wasteful processes of cultivating their soil, they have it to do. There is no mistake about it—they have either to mend their ways, or starve, or go to Texas. They must, as one of the first steps towards amendment, stir the sub-soil. We hope we have convinced them of that. Then they must go to ditching their hill-sides, to prevent any more of the cream of their soil going to enrich the bottom of the Atlantic, where it is not needed just now. Quite enough has been already sent off, by our bad management, on that mission. If you want encouragement in this reform, look at the example set you, by Mr. CUNNINGHAM, of Greenesboro', Mr. HARDWICK, of Hancock county, Capt. EGGLESTON, of Mississippi, and Mr. CALHOUN, of South Carolina. We have told you, in the pages of the CULTIVATOR, something of what all these gentlemen have done, or are doing, with hill-side ditches, except Capt. EGGLESTON. Mr. SOLON ROBINSON, in the last number of the *Albany Cultivator*, enables us to add to the others, an account of Capt. E's. practice:

"His place is all hilly, thin, oak land, very light soil, that melts away in water not *quite* so easy as salt or sugar; and yet he has scarcely a gully upon the whole farm; but he has more than 20 miles of hill-side ditches, which are so constructed, that they take up all the surface water, before it passes far enough over the ground to form gullies. While riding over the plantation, I found one of the overseers engaged, with a large force of hands, laying off and making ditches upon some new ground, it being a rule never to put in a second crop until the land is ditched. * * The rows have to conform to the ditches, however crooked; and the manner of plowing, is to lay off the rows in the first instance, the middles being often left unbroken, until after the corn is planted, and perhaps up. Capt. E's. plan is, to plow deep directly under the corn, and plow shallow while tending the growing crop His motto is to plow deep for all crops. He assures us that, since he has adopted the level system of ditching and plowing, that in addition to the advantage to the land, that his crops are better and the soil improving instead of deteriorating."

In the Southern States, some persons, as we have noticed in our travels, have tried the plan of horizontal plowing, omitting altogether the hill-side ditches. This is a ruinous error. Those who have tried it, have found it so; indeed, in the nature of things, it cannot be otherwise. It is far better to continue the old system of plowing straight up and down hill, bad as that is. Let hill-side ditches be made first; then, and not till that is done, should any one attempt to plow his ground horizontally, unless he wants to send his soil on the bootless mission hereinbefore mentioned.

The way to get credit is to be punctual; the way to preserve it is not to use it much; settle often—have short accounts.

The North-West.

Michigan, Wisconsin, Iowa, and the whole region thereabouts, would seem to be a very paradise for grain-growers. The extreme fertility of the soil, the enormous crops it produces, the small outlay of labor necessary to make and gather a crop—the high price it commands when taken to market, the salubrity of the climate, every thing seems to conspire to make the Northwest a most desirable region to those who can endure its cold. The *Racine Advertiser* says:

"Two farmers from Jamesville, in Rock county, whose farms adjoin, last fall conjointly had 200 acres of prairie broken and sown in wheat—the work being performed by two young men, with ten yokes of oxen, and two boys to drive a few weeks. These 200 acres of wheat have recently been cut by means of a machine, occupying only 12½ days, with an extra expense of fifty cents an acre for binding and stacking. The wheat turned out an aggregate of 5000 bushels, worth $2,500, or an average of 25 bushels to the acre. On Friday the owner came to Racine with two wagons, loaded with an aggregate of 205 bushels of wheat, which he sold to Mr. Richmond at 62½ cents the bushel."

Then we have an account of the soil of this region by Mr. WHITNEY, who has lately gone over it, from Lake Michigan to the great bend of the Missouri. He, it will be remembered, has been looking out for the route of his great Railroad to Oregon. Hear what he says of the country:

[From Mr. Whitney's letter in the Nat. Intelligencer.]

"Before leaving Prairie du Chien I fixed upon a route I would like to pass to the Missouri, and with compass in hand made it within five miles of the point started for. By Burr's map of Wisconsin, embracing Iowa &c. (which I found more correct than any I have seen,) we crossed Turkey river at Fort Atkinson, north latitude 43° 15'; thence we crossed the different branches of the Wabisipinica and the Cedars in about the same latitude to Clear Lake, in west longitude 93° 25'; thence northwesterly until we came to a branch of the St. Peter's, running northeasterly—and I will here remark that we did not find the Cedar's or St. Peter's branch to correspond with Burr's or any map I have seen; thence due west to the Des Moines, in latitude 43° 20', and west longitude 95°, which streams we crossed by felling trees for a bridge; thence due west to a number of small beautiful lakes forming the head-waters of the Little Sioux, and emptying into the Missouri; thence across Floyd's river; thence due west across the branches of the Calumet and the Calumet; thence to the Whitestone or Vermilion, then Jacques river, and then to the great, the grand Missouri, fifteen miles below the great bend; making a distance from the Mississippi of more than five hundred miles, over the finest country upon the globe, capable of sustaining more than three times the population of the same space in any other part of the world: no swamps, no marshes, no flooding of rivers, except in the vicinity of the Wabisipinica, and then only for a small distance, and undoubtedly the most healthy country in the world. I have never found the atmosphere so pure; the surface gently rolling to an almost level; always, however, enough undulating to let all the water off.

"While on this subject I will remark that none of the rivers west of the great lakes are natural rivers, but have formed themselves and beds by the constant wash of this vast and almost level plain. The soil of this vast wilderness is as rich as it can be—none richer in the whole distance. I did not see half an acre of useless or bad land; all covered with the finest of grasses, and, when cured, good hay. The farmer will want but the plow, the seed, the scythe, and sickle. As far as the Cedars (ninety miles west of the Mississippi) are considerable tracts of good timber, but none beyond to the Missouri, and then very little, till nearly down to Fort Leavenworth, and then only about three miles wide, and sometimes none on the river; but coals are abundant, and the growth of timber so natural that, without the fires, (which now spread over the whole prairies yearly, consuming every thing,) in fifteen years

the whole, from river to river, would be one dense forest."

[From the Alton Telegraph.]

"The quantity of standing corn, which may be seen from Mound Farm, in Jersey county, under twenty miles from this place, cannot amount to less than *five hundred thousand bushels*. Nor is this all, or the best. From Mr. B. A. Davidson's residence on the bluff, on the road from Alton to Edwardsville, and about seven miles from this city, there may be seen, without moving from the same spot, by looking only in two directions, fields of standing corn, the probable yield of which is estimated at *one million five hundred thousand bushels*. Beat this who can!"

Extraordinary as is the fertility of the soil in that region, and large as the crops are that grow on it, larger crops are gathered elsewhere from soil made fertile by the hand of the husbandman. The *Liverpool Albion* states an instance in which a man made at the rate of 80 bushels of wheat to the acre. His land had been prepared for wheat by the previous culture of potatoes and cabbage; and it had been stirred in the cultivation of the previous crops to the depth of *four feet*.

To come nearer home—we find it stated in the *American Farmer*, that Mr. SMELTZER, of Frederick county, Maryland, raised of the "Oregon" wheat, at the rate of over 50 bushels to the acre, the seed sown being not quite one and an half bushels per acre.

The same gentleman also raised the "China" wheat, at the rate of 47 bushels per acre—a new kind which ripens early, and is said not to be injured by the fly, mildew or smut.

These are the results of careful cultivation and thorough tillage of the soil. In the English example, the soil was, besides being made rich, loosened by trenching to the depth of FOUR feet. This would seem to be useless labor, if we had not the authority of TULL for the fact, that in properly prepared soil, the roots of wheat have been traced to the depth of two feet.

Yankee Enterprise.

The farm of Mr. PHINNEY, of Lexington, Mass., is perhaps one of the most striking instances of what Yankee energy will undertake and accomplish. It contains about 160 acres, and most of it originally, was very rocky and rough. Mr. BRECK, of the *New England Farmer*, says that according to an estimate that had been made, every six feet square of this farm contained a ton of stones, leaving out of the calculation the immoveable ones. This will give, he says, more than a thousand tons to the acre. Yet they have been removed; and the land that was once thus covered, is now producing luxuriant grass, or is planted with apple and peach trees—and in their season with potatoes, melons, &c.

Just think of that, ye lazy *conks* of our sunny South, who will plow round stones and stumps, and over logs, day after day, and year after year—just think of removing a thousand tons of stones from an acre before you can plow it at all; and let shame burn your cheek, because that, with so great natural advantages over Yankeedom—with our generous soil and abundant means to enrich it, with our genial atmosphere and glorious sky—this end of Uncle Sam's heritage is allowed to wear such an aspect of dilapidation and misery—to look so much like the very fag end of creation.

Mr. PHINNEY is clerk of the county court, and his office is some 8 or 10 miles from his farm; yet, by early rising, he looks over his farm every morning, goes to his office, discharges its duties, returns, and looks over his cattle by light of lantern. There is industry for you—another trait of Yankee character that we want to see imitated in this our blessed land of sunshine and idleness. Here's another example. The *Baltimore American* says:

"The town of Rome, in Western New York, containing a population of over 5000, has been built up by factories for making paddles and oars from the ash, thousands of which are shipped by almost every vessel for England, France, Germany, Prussia, Sweden, Russia, and throughout all the East. The Junks of the Chinese are now all managed by American oars, and the small boats of all Europe and Asia, are now propelled by the enterprise of the people of this one village."

Good Lecturing.

The editor of the *Star of Florida* discourses after the following fashion, of the exceeding great folly of his neighbors, in buying what they ought to raise at home. We like these simple truths told in this plain way; and we hope that paper will continue the hoarhound until there shall not be found in Florida a planter who shall not be ashamed to be caught buying a bushel of corn or a pound of bacon—a plow or a wagon—a broom or an axe handle, that is not the production of Southern labor. These Southern States ought to be independent of the world. The people have the means of making themselves so, if they will but use them.

From the Star of Florida.

A WORD TO THE FARMERS.—Corn was selling in the Tallahassee market this morning at 31½ cents per bushel. The average price of the last crop we suppose not to have been over 37½ cents. The average price of Cotton of the last crop was perhaps 4½ cents.

The price of Bacon in the same market is now, and perhaps the average price during the season has been, 10 cents per pound.

Yet, notwithstanding the relative price of these articles, there are many thousand tons of Bacon annually brought here from the Western States and sold to our farmers at these high prices, and their cotton sold at ruinous prices to pay for it. Can there be any wonder why our people should be embarrassed?

But with some of our people there is a worse state of things than this. The farmers of Leon county, as we have remarked, make corn at 37½ cents a bushel. In a neighboring county, less than fifty miles from Tallahassee, a large portion of the farmers depend upon the New Orleans market for their supplies of corn, which they receive by the way of the Chattahoochee river at a cost of not less (in general) than one dollar per bushel. They depend upon their cotton crop, and their tobacco crop, to pay for their bread and meat. Can such a system lead to anything else but hard times and embarrassment?

Again, the Florida farmers have an abundant supply of most excellent timber, for all mechanical purposes, at their own doors. They have an abundant supply of mechanical skill, if properly encouraged, in their own neighborhoods. Yet if a Florida farmer wants a plow, he sends off to the next market and buys one which has been imported from Yankeedom, and pays five dollars, and makes cotton at 3 or 5 cents per pound to pay for it. If he wants an axe handle, scythe sheath, or any article of a similar sort, he pursues a like course.

By such a system, hundreds of dollars are annually sent abroad, which might with very little trouble have been kept at home.

"But," says the farmer, "I want to buy plows and so on, where they can be had at the cheapest rates. If I want an article made at home, I must run after the mechanic, hunt him up, and then perhaps he will ask an exorbitant price. But I deal with Mr. Sharp the merchant—he takes my cotton—I trade it out with him—and it is very *convenient* to get anything I want from him."

Yes, there certainly is a sort of *convenience* in getting what one wants without much trouble. But yet, on the other hand, there is a very great *inconvenience* in being made to pay through the nose, for what one doesn't want.

Now, it may sometimes seem to the farmer that he pays less to the merchant for an important article than the same would have cost him if made at home—when in fact such is not the case.

When a farmer buys an article which has been manufactured abroad, he must pay for it in cash, or in some commodity that will command cash, at the place of manufacture. And as cotton is almost the only article grown at the South which commands cash in a foreign market, it follows as a matter of course, that the farmer must continue to grow cotton, even at the most ruinous prices, so long as they purchase their principal articles of consumption abroad.

But if the farmer procured his manufactures from a neighbor, even at a *nominal* higher price—yet the money would remain at home, and a large portion of it would, in the course of the year, find its way back to the farmer's pocket again.

The mechanic must have timber to work up in the different branches of his trade. And he pays back to the farmer some portion of his price of his plow, for what, otherwise, would rot in the forests. The mechanic must procure from the farmer, bread for himself—corn and fodder for his horse—shucks, pumpkins and turnips for his cow, and many other articles which the farmer could not send to the North to pay for a plow.

And it may therefore often be really cheaper for the farmer to pay *nominally*, a higher price for an article if made at home, than a *lower* price for an article of foreign fabric.

Deep Plowing.

From all parts of the country where sub soil plowing has been tried, the testimony is uniform in its favor. We do not know of a single exception. Even the political papers are urging its importance on their readers. The *New York Tribune*, for example, says:

"As to deep plowing, all science, all practice, all authority recommend it, and yet three-fourths of our farmers persist in skinning their land over from five to eight inches deep, or not half what is required. We saw field after field of corn which will not yield ten bushels to the acre, (and poor stuff at that) which might have been put up to twenty by deep plowing alone. Of course, one year would not exhibit all the benefits of this culture, though even the first year, if a dry one, would show its decided advantages, but let land have time to get used to deep plowing, and it will tell you plainly how it relishes that treatment. And the man who plows deep is pretty apt to put something else into the soil as well as iron. He will have muck and peat from his swamp holes and a noble compost heap near his barn.

"We hear farmers complain, and most truly, that they can make nothing by their business—and this while they are paying taxes, keeping up fences, and perhaps paying the mortgage interest, on twice as much land as they can cultivate well, and letting half of it go from year to year, without tillage, without fertilizing, and often growing up to bushes and all manner of mischief. Now the wonder is not that such farmers do not thrive—the marvel is that they manage to exist. Let any manufacturer, or merchant, do his business after this pattern, and he must fail—there is no help for it.

"But must we conclude that bad farming has become inveterate among our people?—that our farmers have resolved, though they know better, to hold twice as much land as they can till thoroughly, and torment it till it ruins them. We will not give it up. Every farmer we see admits the evils—says he and his neighbors run over too much land, cultivate too slovenly, are not sufficiently wide awake to the march of improvement,

and lay out too much main strength on what could be easier and better done by the aid of skill and science. All are aware that they must farm better or break, for the car of improvement moves on, and the only choice is to ride on or be run over by it."

Chickasaw Pea.

A correspondent of the *South Carolinian*, writing from Greenville, speaks in very high terms of the Chickasaw Pea as a fertilizer. If this pea, after extensive trial, continues to answer the expectations that have been formed of it, we need not, in the Southern States, complain that clover will not succeed with us. We will have in this pea what will answer our purposes just as well.

We shall be glad to hear more of it from those who have tried it; and especially if it be not the same as what is known as the *Tory Pea*, in Alabama, and some parts of Georgia.

The account by the *South Carolinian's* correspondent, is as follows:

"There is, perhaps, no section of country in the upper districts which has improved more in agricultural condition than the "Old Pendleton" neighborhood—the result, we are told, of an Agricultural Society, composed of intelligent and practical farmers. We were struck with the manifest improvement in the breeds of cattle and hogs. The Berkshire cross has here told well, for the very simple reason, we presume, that stock is attended to. We have never seen a finer stock of hogs in travelling through any country. More attention seems to be paid to the Pea culture here than in any section we have been. We are told that it is the opinion of many good farmers hereabouts, that land can be improved to a high degree by the Pea culture. We have no doubt of the fact, if properly applied. There is a Pea, the Chickasaw Pea, which bears most abundantly, and once planted, is almost inextirpable. We have seen it put into corn ground—after the corn was taken off—pastured by the cattle and hogs all winter—in the spring put in oats, and after the oats was taken off the pea came up in great abundance. Now suppose these were to be let alone, and in lieu of the absurd system of pasturing stubble, the *vine* and *stubble* should be turned under in the fall—would not the land be vastly improved? We have no doubt, if the pea were sown on our stubble lands—a peck to the acre—and the crop turned in, while in the bloom—that the effect produced would be equal to the best clover leys, so much esteemed in Virginia and the North. It is an admitted fact, that leguminous plants exhaust a soil in a very slight degree.

"The Pea vine contains about 53 per cent. of Potash, a most important ingredient in all soils for the production of grain or cotton. If this should be returned to the soil, in addition to the carbon and nitrogen contained in the vine, it seems to me that there would be a manifest improvement. It has been discovered by analysis that Cotton wool contains potassa 31.09 per cent.; lime, 17.05.; magnesia, 3.26; phosphoric acid, 12.30; sulphuric acid, 1.22. That the seed contains phosphoric acid, 45.85; lime, 29.79; potassa, 19.40; sulphuric acid, 1.16 per cent. While Corn contains potassa, 20 87; phosphoric acid, 18.80; lime, 9.72; magnesia, 5.76 per cent. The following analysis of straws may not be uninteresting:

	Wheat Straw.	Barley Straw.	Oat Straw.
Potash	½	3½	15
Soda	¾	1	15
Lime	7	10½	2¾
Magnesia	1	1½	¼
Alumina	2½	3	2½
Oxide of Iron,	2¾	½	2¾
Silica, or flint	81	73½	80
Sulphuric Acid	1	2	1½
Phosphoric do	5	3	¼
Chlorine	1	1½	¼
	100	100	100

From the foregoing data we learn, that potash is a most important ingredient in cotton and corn, and that the pea vine and cotton seed would be most invaluable manures---how easy would it be to avail ourselves of both. If a planter should sow 20 bushels per acre of cotton seed upon a luxuriant vine crop, and put it in wheat, is it not reasonable to suppose that the advantage derived would be as great as from a clover ley, and gypsum. We are sure, the elements are nearly the same, and we have no doubt of its effect. It is an admitted fact, we believe, that oats exhaust land more than any other grain crop. The mystery is solved, we think, by the analysis, for thereby, oats is found to contain 15 per cent. of potassa, while barley straw contains only 3½, and wheat ½ per cent. No doubt the rapid growth of oats, and close pasturing aids much in the exhaustion of the soil, and we derive an important lesson from the analysis-- the want of potassa in the soil---which may be supplied by the pea crop, and the keeping off one's stock. Grass does not exhaust a soil, for the very simple reason, that it takes up no potash. Grass contains, carbon 45 per cent; hydrogen 5; oxygen 38; nitrogen 1½; and ashes 9 per cent.

Every old woman in the country can tell us, that post oak and hickory contain the most potash---yet how few farmers know, that this is the reason, why post oak and hickory lands are the most productive. Let a piece of land of this growth be exhausted and turned out, and it will put up pine, which contains less potash, perhaps, than any other tree. For this reason a pine old field will produce but a few years, without manure. In all pine old fields, you will find an abundant supply of silica, and if you only will add the potash, you are certain of a good crop.

We look forward to a day when the Pea crop will be found a most important auxiliary in the resuscitation of the worn out lands of the South. Clover cannot be grown here---the climate is altogether too hot to expect a luxuriant growth to answer for manure. We see no resource left us but the Pea culture. PAUL PRY.

Original Communications.

Sheep and Wool.

MR. CAMAK:—I am glad to see that your paper is becoming the medium of conveying matters of vital interest to the public mind. Trivial experiments in trivial farming has been the dead weight which has overburdened almost every agricultural paper, and eventually created a disrelish which has condemned them to failure. Some of your correspondents have come to your aid in a branch of production, which must, ere long, constitute a source of great revenue to individuals, and render the South an independent people. If Georgia does not become a large wool-growing State it will be for reasons wholly unassignable. It cannot be for the reason that we have not territory and climate perfectly adapted to it; nor can it be, that it is unprofitable. I will not place wool-growing upon the ground of patriotism, for that basis is apt to yield to the weight of individual interest. So far as you have expressed the desire that we should and ought to become *independent of the world* to supply our wants, every Georgian will concur with you. That we can do so in the main and necessary articles of food and raiment, I believe with you, that *we can*. There seems to be no doubt among men of reflection, that Georgia must, ere long, from position and conformation, become a manufacturing State; and it is not only the manufacture of cotton, but almost every branch resulting in an entire supply of such as we need. This end I am certain you wish to forward.

As it was intended in this paper to bear testimony only to the sound doctrine expressed by some of your correspondents in relation to wool-growing, it will be confined to that matter. Coincidence in the opinions of a few men results in forming "public opinion." I cannot promise any methodical arrangement in this matter, but as an idea arises I will put it down in ink, good or bad. Can we or not, raise wool? This has been settled long since. I might say it had been done in every county in the State; but to do it as a source of actual income is the point which is most material to prove. If it is not profitable and cannot be made so, no proof on paper will change our production of cotton. If more money can be made or saved by making cotton than raising wool, no conviction on paper will induce people to turn to wool-growers. But I am under the impression that a portion of our State can, and will be convinced, that wool-growing is the only resource of permanent profit left to us in time to come—I might say at this time. The Cherokee district is yet too fresh; although the greatest part is fit for very little else in agriculture, still the people will not alter their production from grain to wool—I mean, to take it up as a main and leading production. Although no country on the continent is more suitable than some sections of Cherokee, it will not be done. Where anything, cotton, corn or silk, can be produced with greater profit than wool, let it be done. Where wool meets with such competition it would be abandoned. For this reason, although the climate and soil of the cotton region of Georgia might be entirely suitable, the rivalship of cotton is too powerful. We must then look for a theatre where wool would be free from such competition. The counties of Hall, Habersham, Rabun, Franklin, Clarke and Madison, either entirely or in part, present every inducement to embark in this matter. The best evidence is that which is in reach. To prove anything by conjecture or supposition is useless where money is concerned. To induce men to take up a new business, I must prove that it is not only possible, but profitable. The members of the Western bar are all in reach, if called on, to prove that it is *possible;* if not to raise wool, certainly to raise better mutton than in New England. I understand such to be the case in Habersham and Rabun. The possibility is therefore settled. I do not say better *wool* than New England, but I will say, better than the foreign wools from Smyrna and Buenos Ayres. The wool from Smyrna looses about one-half when washed after it reaches our market. That from Buenos Ayres is always coarse, and it is imported because it is *cheap*—perhaps the cheapest. I mention these counties of Hall, &c., because we all know them. They are to become our allies in this production. This place would be the market for wool grown in them.

The average yield of sheep is better known to the farming people than to me. But we may put it at 3½ pounds for sheep well housed and pastured. This, if managed neatly, would be worth 30 cents per pound, or about the cost of the sheep per head, leaving out the increase from a flock. It is rarely that we find a man who does not admit that wool-growing would be profitable in this section—perhaps not one in a hundred; and many are anxious to test the matter, and are willing to risk much larger amounts than the Southern people have credit for. But in the history of the world there is no parallel to the insignificance of the cause which prevents this outlay of capital in Georgia. I might say with truth, that millions of dollars are lost to the State by those worthless dogs which are allowed to wander and depredate, utterly useless to their owners. Now is there not a species of madness about us to suffer this annual loss, and make no effort to better our condition? I know we cannot get protection from the Legislature; at least, no law will ever be passed embracing the whole State. No party, no legislature, will have the independence to save us from the fate of Acteon. Neither parties nor individuals will hazard their vanity or popularity by introducing a "dog law." But if we cannot get a general law, let old Clarke do her duty. If we cannot get Clarke county to do it, by her people openly and freely asking the Legislature to protect us in the attempt, let

us of this, the Athens district, sign our names, requesting the Legislature to pass a law giving us the privilege of excluding these miserable depredators, that "make night hideous," from our district. Let us agree upon the provisions of a bill which will insure the success of the experiment so far as it may be impeded by dogs.

Clarke county has led forward nobly and successfully—the first to propose, adopt and urge on the great railway system in this State. The money of her people has been laid down to effect it, and at great personal sacrifice. There is no parallel in monetary affairs to the patience and endurance of her people under the adverse circumstances which have impeded her enterprise. Clarke county stands the noblest example of the manufacturing interest in the South. Their capital was pressed into it when it was deemed hazardous if not chimerical, and her manufactured produce is now greater than in all the State beside. Let us take one more step in advance of public opinion—let us be fearless of the result. If we cannot induce politicians to do their duty, let us do ours. We have no hope of obtaining a dog law to protect the whole State; let us then protect our little district. As for myself, I am not above the influence of party feeling; I may admit that I might be considered rancorous; but notwithstanding the admission, I am willing to pledge my vote to any man of any party, to forward these ends, regarding the matter as one of the highest interest to the people. This county, as well as those immediately north of us, are not adapted to cotton, except in a slight degree, and they become less so every succeeding year. We are, therefore, I might say, driven to make something else, and it is fortunate that we have a resource which promises so well. Separate from the individual profit to the wool-grower, the interest and prosperity of this town and the merit of a good example, will, by success, extend the action of the law to other districts in this county, and to other counties. These few counties can make nothing else on a large scale—and I might say that the population favors the project, because there is not a sufficient inducement in the present worn out condition of the lands to employ a large Negro labor; and in this business the poorest man can employ some capital and reap a reward which, under existing circumstances, he cannot do. Any man can own a few sheep. The very poorest can make something with less trouble than by any other means, if he is protected from devouring dogs. Let us go to work and counsel with our neighbors and settle among ourselves what we can do for the country.

If we cannot induce the whole country, let us reason with a part, and that part our own neighborhood. And in our consultations we may present forcible opinions to each other. It appears to me we would come to the point at once. We do not wish to raise wool to make broadcloth, at least not at this time. We can make such as is suitable to the existing state of manufactures. They cannot make broadcloth now, and never will unless we justify them in obtaining men and machinery, and this they cannot do unless there is a regular and full supply to retain these requisites in their service. The wool we would make would be such as they want now, and they would manufacture the description of goods which we want. If we cannot get broadcloth we can wear Southern kerseys and satinets, and we should merit much more, dressed in that, than if we were full rigged in superfines from Old or New England.

I believe such privilege or protection, call it as you like, would raise the price of land when it was in operation. I am certain on this point. Perhaps there are 10,000 acres of land in this district utterly useless as a source of income to the owners. The most of it the owners would not acknowledge as their property if they were not "stirred up with a sharp stick" by the tax collector. But, poor as it is, every acre of it, perhaps, would pay to the owner two or three dollars per annum, without any enrichment of soil, if permitted to use it in the manner proposed. This is more than the land is worth now, or ever will be, without this change. My opinion is, that the privilege extended to one or more districts would induce people to come within the limits with their money to be so invested. The town, the manufactories and the people, are all to be benefitted by such a movement. Let the unanimous petition of the district place us, if possible, for the third time, at the head of a great enterprize. N.

Athens, Oct., 1845.

Suggested Plan for Improving Soil.

Mr. Camak:—In the South, to be successful, we must have an agricultural literature of our own. The same plan of operations is not equally well adapted to every section of this extensive country. That which answers an excellent purpose in a cold latitude may succeed but very indifferently in a warm climate. Theories in farming may many times appear beautiful upon paper which turn out most badly in practice. I would give more for the experience of one intelligent practical farmer than for a thousand theories that have never been tested by actual experiment. The experience and experiments of the best and most successful farmers of this section of country is what we want. Will the farmers and planters of this region withhold this information any longer. I would fain hope not. Come, gentlemen, let your communications adorn the columns of the Southern Cultivator—a paper that will well compare with any agricultural paper published either South or North.

So far as my observation has extended, in the South we have three kinds of agricultural doctrines taught. One class of individuals says, wear out your land and move away. Another says, use prudence by resting the land and other means so as to make it last as long as you conveniently can, and then move. Others say, so manage as to improve both the soil and crops. I believe the last to be the soundest doctrine.

This doctrine cannot be carried into practice, however, without manuring. The next difficulty is, how can that be effected by the least possible expense of time and labor. Now for the practical part: I will take ten acres of perfectly exhausted land—surface sandy with a clay subsoil. Next month I will sow half a bushel of rye per acre, which I will turn under with a one horse turning plow, being careful not to cover so deep but that it will come up well. Next May, when the rye is not yet matured, I will sow upon, and right among the rye standing as it is, two bushels of corn, (mixed with cow peas, say one peck,) on each acre. Then, when the corn is about tasseling, I will sow rye again and turn under the corn and peas. The following spring, I will lay off and plant corn, and so soon as it comes up I will, with a turning plow, cover up for manure all the rye that is growing in the spaces between the rows.

Will any of the readers of the Southern Cultivator point out the defects of the above and communicate by means of the Southern Cultivator, a better method? The following are some of its advantages: The growing rye will keep the land from washing during the winter rains. It takes less of rye than of any other grain per acre to sow land. After the corn crop is raised, sow wheat or oats or rye, and then corn and peas, broadcast, and turn under, and then a crop of corn or cotton. By that means the land produces a crop every year except the first—that is, next year. By repeated plowings, in sowing and turning under the manures, the land will be kept free of weeds, &c.

How will such a plan do? Intelligent farmers of the South, an answer is respectfully requested. I have named a one horse turning plow, because all the most experienced farmers say that too deep plowing will ruin the land in this region. I ask for information. I make no pretensions to agricultural experience or knowledge myself. Charles D. Davis.

P. S.—Should any one see fit to suggest another plan, the comparative expense and the *modus operandi* is requested to be given.

Sugar Cane--Inquiry.

Mr. Camak:—A few of us in the vicinity of this place, who are your subscribers, wish your opinion on a subject about which we differ. It is the mixture of the two kinds of sugar cane. Where the green and ribbon cane have been planted very close to each other we have discovered a third kind, partaking of the nature of both the other plants, but not exactly like either. It has a blue color, but has not the stripes of the ribbon cane. In texture, it is softer than the ribbon and harder than the green. It contains more sap than the ribbon, but not so much as the green. But the sap contains more saccharine matter than that of the green, and not so much as that of the ribbon. Some of us think it is a mixture of the other two kinds, while others think they cannot mix, as they never bloom or bear seeds. As we have agreed to refer the matter to you, you will please give us your opinion; and if you believe such plants mix, say, by what process in nature such mixture is effected. Respectfully yours, Quisque.

Buckeye, Laurens Co., Oct. 4, 1845.

Lime.

Mr. Camak:—Upon the suggestion of the Rev. C. W. Howard, I take the liberty of addressing you, upon a subject in which I presume you will take some interest. We are preparing to burn *lime* in large quantities, under an impression that the demand for agricultural purposes will be great when its value as a manure comes to be properly appreciated in Georgia. Our quarry is situated immediately upon the line of the railroad in the valley of the Conasena creek, Cass county. The rock is of a superior quality, and we have every advantage necessary to burn it with economy. We desire to obtain your opinion as to the probability of its being used by the planters of your acquaintance, and what will be the maximum price they will give for *slaked lime* per bushel. We should also be happy to receive your good offices in making known through the Cultivator the fact of our being prepared to supply any orders after the first of December. As soon as I can ascertain the exact rate of freight upon the railroads I wish to insert an advertisement at fixed prices per bushel or barrel. The cost of transportation is the main *item*, and I am afraid the Railroad companies will charge too much.

We design at the outset to put the price as low as possible, as only in this way can it be brought into immediate and extensive use. The liberal use of lime as a manure, by fertilizing the soil will increase its production, and thereby cause a large surplus to be sent by railroad to market. It appears to me that this argument ought to induce the companies, as well for their own interest as that of the agriculturist, to fix the rate of transportation at a *minimum*.

Mr. Howard desires me to ask you to speak upon this subject to Col. John Billups. He is a large planter, and one who, it is probable, would be likely to appreciate the value of lime as a manure.

Please excuse any trouble an early attention to this letter may give you.

Your obedient servant,
Wm. Spencer Brown.

P. S. At the *advertised rates* of freight we can afford slaked lime at from 25 to 30 cents per bushel; of course, as the rates are reduced the price will fall in proportion.

Rome, Floyd Co., Oct. 10, 1845.

Liquid Manure.—The Chinese, who are particularly skilful in the management of manure, are extremely careful not to waste the smallest portion; and, according to Sir George Staunton, they prefer the dung of birds to that of all others, and next to that, night soil, which they apply in a liquid state.

Agricultural Meetings.

Agricultural Meeting in Barbour County.

A meeting of the Barbour County Agricultural Society was held on Saturday, the 4th instant, in the Town Hall in Eufaula, Ala.

The President, Col. A. McDonald, in the Chair, and H. Hemphill, Secretary.

The object of the meeting having been stated by the President to be, to make arrangements for the approaching anniversary of the Society, and the Agricultural Fair to take place on the 5th day of November, being the first Wednesday in the month.

The following letter from Dr. J. M. Raiford to the President of the Society, was read, on the subject of giving premiums for fine cotton:

GLENNVILLE, October 3, 1845.

COL. McDONALD:—*Dear Sir*—Owing to physical indisposition I shall not be able to attend the Agricultural Meeting in Eufaula to-morrow. I regret it very much, as it has been my desire at that meeting to consult with the farmers of the Society, on the subject of the proposition I suggested to you, when I saw you last.

The proposition is this: that some ten or more of the farmers *who belong to the Society*, contribute the sum of five dollars each, which shall be appropriated to the purchase of a suitable silver premium to be awarded to the individual who exhibits the best lot of ten, fifteen or twenty bales of cotton, (the number can be definitely fixed by the competitors,) at the Agricultural Fair on the 22d November next. The same rules and regulations that were observed by the Apalachicola Chamber of Commerce in the examination of cottons and award of premiums, in the years '41, '2, '3 and '4, to be observed in the award of the premium under consideration.

At a glance, my dear sir, you discover the great benefit such an exhibition would exert on the immediate interest of the competitors, by causing them to take more pains in the preparation of their cottons, thereby improving the quality and price, and also in awakening a spirit of emulation in others to excel in the management of this important article. Ultimately it will have an incalculable beneficial influence on the prosperity and reputation of the country, and will also be of vast benefit to Eufaula as a commercial city.

I would be glad that you would bring this subject before the attention of the Society, and if the proposition takes, let me know soon.

With respect, &c. JOHN M. RAIFORD.

The following gentlemen were appointed a committee to take into consideration the matter contained in the letter of Dr. Raiford, and report to the Society, to wit: Col. J. L. Hunter, Gen. C. Shorter, John A. Calhoun, Esq., and Abner McGehee.

On motion of W. S. Paulin, Messrs. Calhoun, Flournoy and Archer, were added to the Executive Committee.

The President offered the following resolution:

Whereas, there is the greatest diversity of opinion as to the extent of the present crop of cotton; and whereas, it is believed that owing to the unparalleled drought that has prevailed throughout the cotton growing sections during the past summer, that there will be an immense falling off of that valuable staple from the amount made the previous year; and whereas, it is a matter of the deepest interest to the cotton planters as well as the community at large, to ascertain as near as possible the extent of the crop or the quantity made:—Be it resolved, That the corresponding Secretary of the Barbour County, Agricultural Society, be requested to commence a correspondence with the growers of cotton in the different sections of the cotton growing region, for the purpose of ascertaining as near as possible the amount of the crop, and lay the correspondence before the next meeting of the Society.

The Committee appointed on Dr. Raiford's letter, made the following report:

The Committee to whom was referred a letter from John M. Raiford, Esq, Vice-President of the Society, on the subject of offering premiums for fine cotton—report that they have had the same under consideration, and recommend that a subscription be opened at one or two dollars for each individual—the amount collected to be equally divided between the successful competitors of two lots, one of five, and one of twenty bales, to be exhibited on the 1st Monday in December next, at the market of Eufaula, at 12 o'clock: Provided, also, That if the merchants shall contribute the largest amount of money, that the said cotton shall be sold in the town of Eufaula.

JNO. L. HUNTER, Chm'n,
REUBEN C. SHORTER,
JOHN A. CALHOUN,
ABNER McGEHEE,
} Com'ttee.

The report was taken up, and upon motion of Mr. Calhoun, the same was laid upon the table, to be considered at an adjourned meeting, to be held on Saturday next, at which the merchants be invited to attend.

Resolved, That the President appoint a committee of five to award premiums and make arrangements for a Fair to be held at the Market House in Eufaula, on the 5th day of November next.

Resolved, That the proceedings be published in the Eufaula Democrat and the Southern Shield.

The Society then adjourned till Saturday next.

The following gentlemen, from the Executive Committee, met and decided on the premiums to be given at the Fair: John A. Calhoun, Esq., Thomas Cargile, Esq., and W. S. Paulin.

For the best stallion, 4 years old or upwards.....$3 00
2d best.....honors
Best filly, 3 years old or upwards.....$2 00
2d best.....honors.
Best colt, 2 years old.....1 vol. Southern Cultivator.
2d best.....honors.
Best year old colt.....1 vol. Albany Cultivator.
2d best.....honors.
Best brood mare, with or without colt.....$3 00
2d best.....honors.
Best mule colt.....honors.
Best bull.....$3 00
2d best.....1 vol. Southern Planter.
2d best.....honors.
Best milch cow.....$3 00
2d best.....American Agriculturalist.
3d best.....Tennessee Agriculturist.
Best 2 year old heifer.....Southern Planter.
2d best.....honors.
Best boar.....Southern Cultivator
2d best.....honors.
Best breeding sow.....Albany Cultivator.
2d best.....honors.
Best 10 yards negro cloth....American Agriculturist.
2d best.....honors.
Best plow.....Tennessee Agriculturist.
2d best.....honors.
Best counterpane.....$1 00
2d best.....honors.

The following gentlemen were appointed judges to award premiums at the Fair: Gen. R. C. Shorter, Wilson M. Bates, Dr. J. M. Raiford, Henry Tolston and Benjamin Gardner.

H. HEMPHILL, Secretary.

Greenville Agricultural Exhibition.

The Society met on Saturday, October 4, at 10 o'clock, A. M. The President, V. McBee, Esq., took the Chair. Several new members were admitted. Reports of competitors for premiums were received by the President, and Committees were filled by the appointment of persons in the room of absentees.

Officers were elected for the ensuing year, viz: B. F. Perry, Esq., President; Col. S. M. Earle and Dr. A. B. Crook, Vice-Presidents; C. J. Elford, Esq., Secretary, and Dr. C. B. Stone, Treasurer.

At 12 o'clock the Society repaired to the lots where domestic animals were collected for exhibition; and notwithstanding the rain and inclemency of the day, the show of horses, cattle, hogs and sheep, was equal, if not superior to anything hitherto seen in Greenville. The cattle were certainly superior to any previous collection. There was a large crowd of spectators to witness the exhibition, all of whom evinced great interest in observing the fine specimens of improved stock.

The examination of the committee over, and the curiosity of the crowd satisfied in the stock line, after an interval for dinner, the Society re-assembled in Mr. McBee's large new building, at half-past 2, P. M. The spacious room was already filled with ladies and gentlemen. Here was to be seen the ladies' department of the day's exhibitions, and the display was truly admirable, both in the useful and ornamental; fine culinary vegetables, fresh butter, tastefully prepared for show, domestic cloth, and rich bed quilts, specimens of knitting, ornamental needle work, and fancy work of great variety, and baskets of choice and beautiful flowers.

The President, V. McBee, called to order, and the committees reported successively on the award of premiums of $5 Silver Cups, as follows:

The Committee on Horses, through B. F. Perry, Chairman, reported, awarding a premium for the best Horse to Col S. M. Earle's Colt—from Bay Maria, by Col. Hampton's Monarch; and to Gen. Thompson's sorrel Filley, out of Zela, by John Bascombe.

To W. M. Goodlett's Mule Colt, the preminm for the best Mule

Col. McNeely, from the Committee on Cattle, reported, awarding the premium to Dr. C. B. Stone's Durham Bull Osceola, 3 years old—and a certificate for the second best to Dr. Stone's Calf Moneco, 9 months old.

For the best Cow or Heifer—premium to Mr. McBee's red Heifer, 7½ months old, by Dr. Stone's Bull, Osceola, out of a fine cow of the native stock, belonging to Mr. McBee; and a certificate for the second best to Gen. Thompson's Cow, a superior animal of native stock.

The Committee on Hogs, through Col T. P. Butler, Chairman, awarded the premium for the best Boar, to V McBee's pig Osceola, by J R. Poinsett's Berkshire Boar, from Col. Hoke's Sow Betty. For the best Sow, to Mr. Bradshaw's Sow Betty, of the same stock.

The Committee on Grain awarded the premium to Dr. O. B Irvine, for the greatest product of Wheat per acre; report on Corn postponed till November.

Premiums for domestic and household manufactures, vegetables, butter, ornamental work, &c., were awarded as follows:

For the best piece of Domestic Cloth, a Work Bag, worth $2.50, to Mrs. Martha Alexander.

To Mrs. Dr. Stone, a Silver Hook and Thimble, for the best Bed-quilt.

To Mrs. Bradshaw, a silver Butter Knife, for the best specimen of Butter.

For the best specimen of Knitting, a set of silver Knitting Needles, to Miss Eugenia Stone.

For the best basket of Flowers, a copy of the American Flower Garden Companion, to Mrs. General Earle.

For the best basket of Culinary Vegetables, a copy of Miss Leslie's Complete Cookery, to Mrs Dr. Stone.

The Committee on Ornamental Needle Work, awarded a premium of a Gold Thimble, to Miss Jane Walker.

The thanks of the Society were voted to Miss Sarah Belcher and Miss Ann Hyde, for beautiful specimens of Straw Bonnets, manufactured by themselves; also to Mr. Bradshaw, for a specimen, in the box, of Honey taken from the "Bee Palace;" also to Dr. T. Croft, for a specimen of Rice grown in Greenville District; also to D. Westfield, for specimens of a Drawing Knife, and assortments of Chisels of superior workmanship and finish, made by him.

On motion, a committee of three, consisting of B. F. Perry, G. F. Townes and C. J Elford, were appointed to select for publication, reports of the competitors for premiums.

V. McBee, Esq., towards the close of the meeting, left the Chair, and called on his successor, B. F. Perry, to preside. Mr. McBee made a brief address on retiring, and recommended various measures calculated to promote the interest of the Society. Maj. Perry addressed the Society and meeting from the Chair, first returning his acknowledgments for the honor of being elected to the post of President; and he suggested various important means of encouraging and securing the permanent existence and usefulness of the Society.

On motion, the thanks of the Society were voted to the late President and other officers of the Society, for the able and faithful discharge of their respective duties.

On motion, Resolved, That the President be authorized to select some one to deliver an anniversary address at the next annual meeting.

On motion, adjourned. V. McBEE, Prest.
G. F. TOWNES, Secretary.

Florida Sugar--Letter from F. P. Miller.

From the Floridian.

We have been shown a specimen of Sugar manufactured by F. P. Miller, Esq, of Jefferson county, (referred to in the letter below,) which is by far the finest sample of Florida sugar we have ever seen. It is nearly equal in whiteness to the Havana box, and is superior to the sugar brought here from New Orleans. Had we the capital to erect proper works, sugar would soon become no small item in our exports. As it is, however, our planters will soon be able to manufacture not only sufficient for their own use, but to supply the demand of our home markets. The annexed letter from Mr. Miller, which has been kindly furnished us by Gov. Mosely for publication, contains some hints which may be useful to those engaged in the cultivation of the cane. We would respectfully suggest to those of our planters who have had experience in the manufacture of sugar to communicate the result of their observations to the public. We should be happy to extend the use of our columns to any one who would favor us with articles upon sugar as well as upon the culture of tobacco, &c.

JEFFERSON Co., Sept. 1, 1845.

Dear Sir:—In a communication which I received from you a few days since, you requested of me to furnish you with an article on the cultivation and manufacture of sugar. I have had some hesitancy in complying with your request, only from the fact, that my opinions would possibly differ with some of the farmers of the country, and some, too, of experience. But, after giving the subject due consideration, and thinking I might be of service to some in my communication, I have yielded to your request; and, so far as I am capable of giving my opinions, you shall have them freely. As I am more accustomed to using my farming utensils than wielding the pen, and knowing better how to make sugar than to describe the operation, you must allow me to give my opinions in my own plain way. In the first place, I prefer the ribbon cane for this climate, for the reason that it will stand the cold spells, which we are sometimes subject to in the fall season, much better than the green. I have noticed in some crops that I have made, where my cane has been mixed, that the green cane has soured after a killing frost, when the ribbon cane would be perfectly sweet. This I consider a great advantage by giving the planter more time to gather in the other products of his farm. The sample of sugar which I send you, was made from the ribbon cane after a severe freeze, which I consider a good test of its preference. I have been accustomed to banking my seed cane in low, flat beds, say about four feet deep, with the roots inclined downwards, and leaving them entirely uncovered with earth until after the first frost, or until the blades are entirely dry. The advantage to be gained by this mode of putting up seed cane, I consider a great one, from the fact that the cane will remain in a warm, moist state, during the winter, and the roots and eyes will not only be perfectly sound by the usual planting time, but will have put forth their sprouts, and secure to the planter an earlier and better stand. The usual mode of banking up seed, by drawing the bed to a narrow ridge on top and covering with earth before the blades are thoroughly dried, causes the cane to heat, and consequently a great many of the sprouts will perish from dry rot.

The kind of soil from which I raised my cane last year is of good quality pine land, about fourteen or fifteen inches deep, of a very light cast, and has been in cultivation several years. Cane should never be planted on first year's ground, from the fact that the juice extracted from it will not granulate. The most favorable time for planting, in my opinion, is about the middle of February, provided there is a suitable warm spell; for I consider the cane to be doing much better by remaining in bank, where it will sprout and remain sound and not exposed to the cold until the earth has become a little warm. My own observation has convinced me that cane planted about this time, will grow off faster, be equally as forward, and the stand much better than when planted earlier. I have usually planted my cane four feet between rows, and very thick in the drill: a stalk of cane six feet long, should lap or be touching. The seed should be planted deep and covered with a turning plow.

The first working which it receives should be done with the hoe, what is commonly called by the farmers flat-weeding. This will break the crust which may have been formed on the surface of the bed, and forward its coming up. The first plowing I usually give my cane is with the turning plow, but after it becomes of any size, I use the sweep. The usual time for laying by, is the first of June, but should it be growing rapidly, I would advise later and deeper plowing, which will check the growth and cause it to mature better.

It will have been noticed by all who are in the habit of using it, that the saccharine matter is greatly increased after the growth has been checked by the first frost; and until then should never be cut for grinding. I am convinced that a great many of the failures in making sugar is caused from the fact of the cane being topped too high, and consequently a good deal of the juice is extracted from cane that is not matured. The best criterion to be governed by is from the blades drying up, and leaving the stalk exposed only so far as the cane is matured; and I make it a rule to cut my cane at the joint above the first green blade, by which means you are certain not to have any cane unmatured. I have found a great advantage in cutting my cane and exposing it to the sun about two or three days before grinding. A good deal of the watery particles will evaporate, without any loss of the saccharine matter. The process of boiling will depend a great deal upon the quality of the cane and its maturity. A person would learn more from seeing a few boilings taken off than from all he might hear or read on the subject. In the first place, I would advise the use of lime, which assists a great deal in clarifying, and causes the grain to be much firmer. My plan of using it is to mix a half gallon of the cane juice with a half pint of lime; after setting a while pour it off. This quantity should be put into a hundred gallons of the cane juice. It is best not to commence skimming until it is nearly in the act of boiling, at which time most of the scum has risen to the surface, and is much easier taken off. There are so many marks by which the sugar maker ascertains when his boiling has arrived at the sugar state, that it would be difficult to describe them all. I will give one or two which I consider most certain: It is known by all who have any experience in sugar making, that, as the boiling approaches the sugar state, the froth or foam is greatly increased, and the bubbles become much smaller, by constantly dipping up and pouring it off from the cooler. It will be seen that the quantity of liquor or syrup decreases very rapidly after the boiling has turned down: this should be continued until there is but a small quantity of syrup left, which will be seen in the drainings from the cooler. Another criterion to be governed by is, when it is ready to be taken off, the bubbles, instead of rising and falling out from the centre, will turn in, when it should be taken off and put into the cooling vessel as soon as possible.

With regard to the process of dripping, I would say that it is all-important to have the molasses well drained from the bottom of the barrels; to effect which, it is necessary to have two or three holes bored in the bottom, into which should be inserted stalks of cane, which will gradually wither and leave the orifice larger at the time when the draining is most needed from the bottom. The hoops should be well loosened after the sugar has been in the barrels a few days.

In conclusion, I would say, that I believe as good sugar can be raised here as in any country, from the fact, that I have seen samples of sugar made in this country, that would compare with the best quality of imported sugar, and if not cultivated as an article for market, should be made by all the farmers for their own consumption.

Yours, truly,

FRANCIS P. MILLER.

To Gov. WM. D. MOSELEY.

Silk Culture in the United States.

From the National Intelligencer.

Messrs. Gales & Seaton:—In your European Correspondent's letter of August 20, published in the Intelligencer of September 13, I find the following paragraph:

"In the Journal des Debats of the 12th inst. there is a column of American statistics derived from the last report of your Commissioner of Patents. Towards the end, it is said that the culture of the mulberry and the raising of the silkworm have utterly and ruinously failed in the United States. 'Let France,' it is added, 'cease to fear American competition: the Union will be for her an immense market.' We may hope that the silk case is not so forlorn with you. What are the *natural* obstacles to perseverance and success."

I assume the duty of answering the very interesting interrogatory at the close of this paragraph. There are NO *natural* obstacles to *perseverance*, much less to *success*, in the silk business in the United States. The obstacles to its progress at present are purely artificial and *ephemeral*. I have had my eye upon this subject now *twenty-one* years. That I might be a disinterested witness even in the public opinion, I have kept myself clear of any pecuniary interest in the culture of silk. I have witnessed its progress, its experiments, its successes and its failures; have scrutinized all the details of each and all; and have never yet found the slightest reason to doubt its ultimate successful establishment as one of our main staple productions.

The reason of its apparent depression at this time is to be found in the very place where it should be most rationally looked for. The late speculation in mulberry trees, called the multicaulis speculation, which I never failed to oppose, and which I never in the slightest degree advanced, caused expectations of profits from the silk business that were not only unreasonable, but wildly extravagant. The failure to realize these expectations by the many that began the culture of silk, and although a *reasonable* profit was at hand, induced its abandonment by thousands. They expected to realize a thousand dollars from an investment of capital and labor that in any other agricultural employment would have been satisfactorily compensated by fifty or a hundred. Disappointed in this extravagant expectation, they abandoned the enterprise. Another obstacle was found to its progress in the go-ahead character of our people, and their want of foresight. They raised large quantities of cocoons before there were means provided for their conversion into any useful article, and had not patience to preserve them till these means were provided. This was a great error, and placed one of the most insurmountable obstacles in the way of our progress.

Let everybody understand that the late multicaulis speculation had nothing to do with our capability to produce silk; that the true friends of the silk culture were always opposed to that speculation, and did all they could to restrain and suppress it, (the writer of this among them,) but that it had the effect of proving conclusively that the United States, from 32 to 42 degrees of north latitude, (longitude without limit,) is well adapted to the silk culture, equal in climate to China, superior to China in the enterprise, industry and intelligence of our people, and superior to France or even Italy in every requisite for the successful culture of silk. *I* may not live to see it, but the time is not far off when even France shall be supplied with silk from this country—all Europe of course. The germ of this great interest is already firmly imbedded in our physical condition, and nothing can ar-

rest its steady progress to an overwhelming extent. The time will come when even cotton will be second to silk on the list of our staple productions. But, before all this can happen, our people will have to learn to be satisfied with moderate but remunerative profits, and to gather these in particles so small that the common or unpractised eye would scarcely discern them. They must also learn to make up large results from small items. Did it never occur to you, Messrs. Editors, that the great difference between our Northern and Southern people consists in this peculiar feature—they of the North are satisfied in collecting large sums from the congregation of extremely small items, almost ultimate atoms; while they of the South can never contemplate with composure anything less than a crop of a thousand bales of cotton, that is to yield them twenty to thirty thousand dollars? Even these latter, *with big eyes*, can only see a large *cotton field* of one hundred to a thousand acres; the individual plant itself is too small for their vision. They forget that it is only from the aggregation of the products of these individual plants that their hundreds or thousands of bales are made up. Now, silk is a peculiarly small article—small, I mean, in physical proportions; but there is no article so well adapted to aggregation into large masses of value.

Please say all this to your much respected correspondent in Paris. Tell him that the self-complacency of the Journal des Debats is misplaced, and bid that Journal and the people of France, and those of Italy with them, beware of "American competition" in the production of silk. Respectfully,

GIDSON B. SMITH.

Baltimore, September 13, 1845.

Rural Architecture in New England.

We extract from the correspondence of one of the editors of the Louisville Journal, travelling in New England, the following notice, effectively descriptive of the character of the improved rural edifices in that country:

"I had a great desire to see the lovely cottages at New Bedford, of which Downing speaks in his Landscape Gardening, but this pleasure I could not enjoy without detaining my companions, and I relinquished it with the less reluctance from having already seen at Boston a number of exquisite rural structures of different styles, built since my visit to Boston in 1843. These are the Italian villa of Theodore Lyman, six or eight miles from Boston, and a group of cottages at Linden Place, near Boston, some in the Italian and others in the English Gothic style, but all differing materially in their details. I wish it were in my power to give your readers some idea of the delightful emotions with which the sight of these exquisite specimens of art filled me. If it were, I might contribute thus to create a taste in the West for rural architecture, of which, I am sorry to say, it is almost wholly destitute. These buildings are all of wood—their cost ranges from $2,000 to $10,000—certainly not more than that of the suburban dwellings of the West generally, and yet they are exceedingly beautiful, perfect gems of architecture, producing an effect infinitely more charming than the most costly Grecian structure. I have seen most of the costly public edifices in this country, but none of them, with the single exception of the new Gothic church in Broadway, New York, give me anything like the pleasure of the cheapest and simplest of these wooden cottages, where effect depends in no degree upon size, costliness or material, but wholly upon the magic of art.

"I am glad to find that in every quarter of the Eastern and Middle States, the Grecian style of architecture, for dwelling houses, is universally condemned and rejected. Every gentleman of taste here would prefer a tasteful wooden cottage, costing but $2,000, to Girard College with its thirty-two immense Corinthian columns. The Grecian style in domestic architecture is now regarded as vulgar, and no costliness or magnificence can redeem it from the air of inappropriateness and upstart pretension. Columns and walls, without visible roof or chimneys look very fine in the ruins of Greece and Rome, and can be endured in legislative halls in America, but in the dwelling house give us the warm hospitable aspect of the old English cottage, with its steep, projecting, bracketted roof, its sharp gables, its swelling and sociable bag-windows, and its long, conspicuous, ornamented chimney shafts—a style susceptible of never-ending variety of detail. But I must refer the reader to Downing's Rural Architecture, trusting that no one will hereafter build the cheapest cottage without first consulting that work, or getting a design from an architect of taste, one who rejects the Grecian styles, and assuring the reader that, however admirable may appear the designs in Downing, the houses themselves appear infinitely finer. Theodore Lyman's Italian villa looks well in Downing, but the villa itself infinitely surpasses the idea conveyed by the picture. I neglected to mention Bute cottage, which was built, I think, previous to my visit in 1843. It is a small cheap cottage, but it is, to my eye, the most charming of all. I noticed one defect, and that was in the color of the verandah, which is green, and does not harmonize with the other colors of the building. The new cottages are none of them white, but of some quiet unobtrusive color, drab or light chocolate."

A Chapter on Feathers and Feather Beds.

From the Indiana Farmer.

He is poor indeed, in this land of abundance, this paradise of geese, and turkeys, who cannot feather his own bed. At the West, at any rate, whatever other thing is wanting, none need lack a feather bed; no girl is of a marriageable age or condition who has not earned a feather bed. The careful mother, intent on her daughter's dower, weaves her sundry woollen blankets, (ye gods of the loom! how thick and warm, and cosey, of a winter's night!) and makes her a huge, well-stuffed feather bed.

The Dutch, when fresh from "fader-land," sleep not *on* feather beds merely, but *under* them, employing them instead of bed-clothes.

It is very well, then, to attend to the science of feathers, or as the old sermonizers used to say, their "origin, nature, and uses, with some practical reflections."

1. The best feathers for domestic purposes are geese-feathers, being the most elastic and durable. There is about as much difference in their quality as in the wool of different breeds of sheep. The quality depends on their strength, elasticity and cleanliness; and these again, depend upon the condition of the bird, its health, food, and the time of plucking its feathers. *Down* is the term applied to under feathers—most abundant in water-fowl, and in those especially which live in cold latitudes, being designed to protect them from wet and cold. The eider-down, from the eider-duck, is of the most repute. It is brought from extreme northern latitudes, and is used for coverings to beds, rather than for beds themselves, as, by being slept upon it loses its elasticity.

Poultry feathers, as those of turkeys, ducks and chickens, if assorted and the coarse ones rejected, afford very good beds; but they are not so elastic as geese-feathers.

2. Everybody knows that live geese-feathers are the best. Every one does not think of the reason; which, as it is the key to the art of having good feathers, we shall propound.

So long as a bird is alive the feathers are as much an object of nutrition as the flesh, the bones, or any other part. When the bird has been for any time dead, its parts relax, and the feathers are also affected, although from their chemical elements, the decomposition is not as rapid as it is in the flesh. But it *begins*. They lose their glossy color, their spring or elasticity, and like the rest of the body, they are dead.

Those feathers are best which are plucked in the very height of health and growth. It is well known that sickness changes the hair and skin of animals. A dull colored hair, dry and rough, is a concomitant of sickness in the horse, ox, &c. On the other hand, a bright, glossy hue is a sign of health. Every one has noticed the same thing in fowls—the drabbled, rumpled, lack-lustre plumage of sick ones. The higher the condition, and the more vigorous the health of a flock of geese, the better the *fleece*; while a meagre, draggling, half animated flock, never will yield *live*-geese feathers.

The same results arise from the *age* of feathers. They ripen and are shed as the hair of animals. At the time of moulting the feathers are dry and lifeless—because they are spent, and are to be cast off as dead. When fowls are killed, the feathers will be alive and good, if immediately plucked off before the body grows cold. Sometimes geese are plucked five times a year, but only when they are owned by a greater goose than themselves. Such avarice defeats itself. No geese can be healthy under such cruel extortion; and, without health, feathers cannot be good; twice a year, in spring and mid-summer, is often enough.

2. After feathers are picked they require careful attention.

Every feather is largely imbued with oil, by which it is defended from wet; and this oil must be removed or neutralized before feathers are fit for beds. This is effected by heat, or by heat and an alkali. As soon as picked they should be spread upon boards and oven-dried, or they will heat and stick together and putrify. Upholsterers prepare the feathers by rejecting from them all coarse ones—the tail and small wing feathers. They are next put into rooms heated artificially, with ventilators at the top to let off all impure vapors which arise from them. In this room they are frequently turned till quite dry. They are put into a coarse bolting machine, and whirled round with great velocity until all dirt and dust is driven off. The whole process of curing will reduce their weight about one pound in seven.

They are sometimes prepared by sprinkling a little quick-lime over them, which combines with the oil and prevents its becoming rancid.

Another mode is to take a pound of quick-lime to a gallon of water, stir it well, then let the sediment form, and turn off the clear water from the top. Immerse the feathers in this for two or three days; then spread them upon coarse nets to dry. Shake them from time to time, and when perfectly dry, put them loosely in bags and beat them thoroughly, and they will be ready for use.

If a recipe is required for a bed fit for a carrion-crow, here it is: Let your geese be as unhealthy as possible. Either pluck them four or five times a season, or, if you kill them, let them lie several hours till cold. Then put them into hot water to make the feathers come easy. In pulling, take out large handsful at a time, so as to have scraps of meat and shreds of skin adhere to the quill; let them lie for several days in wet heaps to ferment a little. Then dry them suddenly by violent heat, cram them into the bed-tick, and jump on, and if you have not an odorous bed, and, in a month or two, a bed full of visiters seeking food, then there is no truth in the laws of nature.

4. *The care of beds*, is not understood, often, by even good housewives. When a bed is freshly made it often smells strong. Constant airing, will, if the feathers are good, and only new, remove the scent.

A bed in constant use should be invariably beaten and shaken up daily, to enable the feathers to retain their elasticity.

It should lie after it is shaken up, for two or three hours a day, in a well ventilated room. The human body is constantly giving off a perspiration; and at night more than usual, from the relaxed condition of the skin. The bed will become foul from this cause if not well aired. If the bed is in a room which cannot be spared for such a length of time, it should be put out to air two full days in the week.

In airing beds, *the sun should never shine directly upon them.* It is *air*, not *heat*, that they need. We have seen beds lying on a roof where the direct and reflected rays of the sun had full power, and the feathers, without doubt, were *stewing*, and the oil in the quill becoming rancid; so that the bed smells worse after the roasting than before. *Always air beds in the shade, and, if possible, in cool and windy days.*

And now, if any of our attentive housewife readers, and we have not a few, are disposed to reward us for all this advice, let them give us a bed to sleep on, when we next visit them, made of growing feathers, from live and healthy geese, carefully picked, well cured, daily shaken up and thoroughly aired; and if we do not dream that the owner is an angel, it will be because we are too much occupied in sound sleeping.

Improvements in Agriculture.

From the Genesee Farmer.

"The great truth that animal manures are nothing else than the ashes of the food produced from our fields, consumed or burned in the bodies of men and animals, has given the chief direction to all modern improvements in agriculture."—*Liebig.*

The above remarks deserve the profound consideration of every practical farmer. After an animal has attained his maturity, and adds nothing to his weight in the course of a year, it is obvious that the matter which escapes from the body must be the same in quantity as that which enters it. A very notable portion of the food of all warm-blooded animals passes out of the lungs in the form of air and vapor during their ceaseless respiration night and day, just as wood passes out of a chimney when burnt in a fire-place. The combustion of grass, hay, and grain in the system of the cow, horse, or sheep is not so complete as that of fire applied to the same substances in the open air. In the latter case, nearly all the combustible ingredients—carbon and hydrogen united with oxygen and nitrogen—are expelled into the atmosphere. In animal combustion, a larger portion of carbon, hydrogen, oxygen, and nitrogen remain with the ashes contained in the food taken into the stomach, and voided with the solid and liquid excretions.

The time will shortly come in this State, (New York,) when the liquid and solid manure derived from the combustion of one ton of hay, or 100 bushels of grain, will be worth half as much to make another ton of hay, or 100 bushels of grain, as the original crops were worth.

That portion of cultivated plants which escapes into the air through the lungs of man and his domestic animals, growing plants can regain by their roots and leaves, and thus reorganize into animal food. But the case is different with the ashes or earthy portion of all plants. If these minerals are taken from the soil in crops, and not faithfully restored, by replacing on our cultivated fields all the *salts* contained in the excretions of the human family and of domestic animals, the injury to our State and our race will be large, almost beyond calculation.

Nearly one-third of all the wheat grown on the globe is raised by the Chinese. For thousands of years this wonderful people have cultivated most successfully this bread-forming plant. For a long period their wheat-fields have been fertilized almost exclusively with the ingredients of wheat derived from its decomposition in the human system. In other words, they manure their fields with *night-soil alone.*

In Belgium and Flanders, the liquid excretions of all animals are diluted with twice or three times their bulk of water, and are then spread over the growing crops, or on to plowed ground, from a watering cart.

Many years of experience have demonstrated the fact, that the urine of a single cow for a year is worth $9.50 to make into wheat to be sold at 70 cents a bushel. In Holland, cows are kept up the year round in stables, mainly to save every particle of their excretions. The manufacture of corn, wheat, barley, oats, hay, potatoes, pork, beef, butter, cheese, wool, and horse flesh, can be reduced to an exact science. The laws of chemical affinity, of vegetable and animal vitality, are *uniform* and easy to be understood, so far as successful agriculture is concerned. One of these laws is, that no man nor vegetable can possibly make *anything* out of *nothing.* Another is, that one simple substance, like carbon, cannot be transformed into another simple element, like nitrogen. Clay cannot supply the place of sand, nor sand of clay. It will require as much matter, and the same kind of ingredients, to form ten million bushels of wheat or corn, in 1845, that were consumed for that purpose in this State in 1844. The same remarks will apply to all agricultural products, whether vegetable or animal.

How, then, can a practical farmer, cultivating 60 acres of arable land, send to market 20 tons of grain, pork, beef, mutton, wool, roots, butter, cheese, and the like, every year, to pay for his groceries, dry goods, nails, crockery, and mechanical work, and not ultimately sell all the ingredients in his 60 acres, which will form crops enough to pay for cultivation, fences, and taxes? Suppose you have the materials to produce 50 good crops in your now fertile soil, when those materials are worked up and sent to distant cities, where then will the largely increased population of the State go to find their three good meals a day, clothing, &c.? Do you say, to the West? But what right has the present generation to consume and destroy the natural fertility of God's bountiful earth, to the serious injury of those who are to succeed them?

By every principle of common justice and philanthropy, we should augment the natural productiveness of the soil at least 4 per cent. per annum, or double its fruits in 25 years. For in that time our race double their numbers, and their physical wants, in the State of New York.

SOUTHERN CULTIVATOR.

VOL. III. AUGUSTA, GA., DECEMBER, 1845. No. 12.

REMARKS OF JAMES A. MERIWETHER, Esq,

Before the Agricultural Society of Putnam Co., May, 1845

[CONCLUDED FROM LAST NO.]

Peat may likewise be rendered a valuable manure by saturating it with the contents of the washtub—by pouring upon it human urine—by pouring on it the slop from the kitchen, and by mixing ashes with it. It is the great natural manure of middle Georgia, and it requires but little art and labor to make it a source of great profit to our farmers. It is found on every branch and creek in Putnam county, and the valley of Leek creek has enough to manure the whole county for years. Mr. Dana, in his Muck Manual, says, "it is highly concentrated vegetable food," and is nothing more than "pond mud, the slushy material found at the bottom of ponds when dry, or in low grounds, the wash of higher lands." Some is more valuable than others; that which is deposited by eddy water is the best, yet all washings contain vegetable matter, and are therefore valuable. It lacks only ammonia to make it equal to cow-dung. Mr. Dana says, "it is certainly a very curious coincidence of results, that nature herself should have prepared a substance whose agricultural value approaches so near cow-dung, the type of manures." "The great question comes, how is to be given to peat, (a substance which in all its other characters is so nearly allied to cow-dung,) that lacking element, ammonia? By the addition of alkali to peat, it is put into the state which ammonia gives to dung. The question then arises, how much alkali is to be added to stable dung? A cord of stable dung composted with two of peat forms a manure of equal value to three cords of green dung. Indeed, the permanent effects of this compost exceeds those of stable dung. The best plan for preparing this manure would be to dry the peat, or swamp muck, in the fall; in the spring of the year let this be mixed in the proportion of 30 lbs. of potash, or 20 lbs. of soda-ash, or 8 bushels common house ashes, to every cord of fresh dry peat. If ashes are used they may be mixed at once with the muck; if soda ash or potashes are used, they must be dissolved in water, and the pile evenly wet with the solution. If spent ashes are used to prepare this muck, add one cord of spent ashes to three cords of peat or swamp muck. There are other sources of alkali for converting peat into soluble matter. It has been actually proved by experiment that a dead horse can convert 20 tons of peat into a valuable manure, richer and more lasting than stable dung." The next great and prolific source of ammonia is the urine.

I have been thus minute in reference to peat, because it is a manure which is to be found on every plantation—is accessible, and by a very little labor is capable of being made very valuable, and it must therefore of necessity, prove to this region of Georgia the basis of all compost manures. We need but a slight acquaintance with its properties to induce us to make a general application of it. It should always be composted with other manures that it may acquire ammonia, the great food of all plants, and which it lacks. Let me urge you to try it; it may be had plentifully for the labor of digging.

Another source of improvement to our lands, is the plowing in of green vegetables. Professor Johnson says, "this manuring is performed with the least loss by the vegetables in the green state. In no other form can the same crop convey to the soil an equal amount of enriching matter as in that of green leaves and stems." The crop should be plowed in while green, for if exposed to the air, green vegetable substances gradually give up a portion of the saline matter they contain to the rains that fall, and hence a great fertilizing property is lost. A distinguished agriculturist in Maryland states on his own experience, that the very best green manure, even better than clover, is green corn. Sow it broad cast; when of convenient height, plow it under—sow again, and again turn it under, and so of the third sowing in the same season. He says, "many suppose the old plan of clover laying, is the cheapest and best; I differ with them; you can put but one clover layer in every two years—you can turn under three crops of corn in a year, and each crop of corn will carry as much nutritive matter into the soil as each crop of clover can do." Let the experiment be tried; the labor bestowed on one acre is not much, if wholly lost; if successful, you have gained a great deal.

There is an indisposition however with many to commence a system of manuring because they say it takes too much time, is too troublesome, and has to be repeated every year, and not having manure for all his land, the farmer concludes it is not worth while to manure any. But is there any truth in these objections? Land well manured will increase the product many fold; by increasing the *fertility* you can reduce the number of acres in cultivation—the time saved in cultivation may be applied to the preparation of manures, by which an annual increase is made, and so in succession are the crops increased and the land enriched. A retrenchment in the expenditures for tools and their repair is effected—an outlay of capital for horses, &c., is saved, and otherwise employed. In fact, it is the most effective system of economy which can be resorted to; for every one knows, that if by a system of cultivation thirty acres of land can be made to yield as much as one hundred acres did before, that there must be a saving in the number of hands and horses which cultivate it, as well as in the food which supports them, and the capital employed. As a matter of economy let every farmer improve his lands, and if he has only manure enough to make 20 acres *tolerably* rich, or ten acres *very* rich, let him enrich the ten, as a matter of economy. Last year I attempted an experiment in this way: I selected one acre of ground very poor, so much so as not to be fit for cultivation. Upon it I placed 300 bushels of manure, and the result was 43 bushels of corn, and 66¼ lbs. of well cured fodder. I do not think that the land would have produced *three* bushels without the manure. The ground was laid off in drills four feet apart, the rows were first run with a scooter, then plowed deeper with a long pointed shovel, and in the bottom of these a long broad pointed coulter was again run. The manure was deposited in the bottom of the furrow—the corn was planted on it, and covered with the plow. The land was then broken with the coulter, once plowed with the shovel, and once hoed. At no time did the corn even wither or droop, while some near by was very much twisted and affected by the drought.

But after applying the manure to the land, a great object is, so to apply it as to make it the most available and enduring. On our broken lands it is subject to be washed away along with the soil, by the heavy rains. To prevent this, hillside ditches have been found to answer valuable purposes. If properly constructed with sufficient fall and capacity, and proper length, they will be found to answer every purpose. In the improvement of broken lands this seems to be the first consideration, and without this preparation the after labor of manuring seems to be badly and almost uselessly applied.

But supposing the ditches opened and the manure ready to be applied, how shall it be done? on the surface, or at the root of the grain?

I apprehend I shall be encountering some old and stubborn prejudices, in advancing the opinion, that it should be applied *beneath* the surface. Broadcast manuring is decidedly to be preferred to that in the hill, because, the roots extending out, pass beyond the limits of the manure in the hill, and therefore draw no support or nourishment from it, save those roots which are immediately in its vicinity, whereas if the manure is spread broad cast, the more they extend the greater the supply of it. If the soil be sandy it would doubtless be best to apply the manure between the surface and the grain when applied in the hill, but on soil not sandy, apply it *beneath* the surface and *beneath* the grain.

A common opinion prevails, that manure sinks, and therefore to benefit the plant, you should place it on the surface, that in making its descent the roots may catch it. But whoever dug into the ground and found where the manure sank to?

But one fact will contradict this theory; ammonia is said to be the life-giving property of manure; this is gaseous—intangible and incapable of being seen—if exposed to the air it escapes, and is lost to the plant. Go to a manure heap, and the offensive smell like hartshorn which meets you is the ammonia. Now if it did not *rise*, but *sank*, then these heaps would yield no smell at all.

To put manure upon the surface is but to expose to evaporation its most valuable parts. Rain and sun, have the effect to dissipate all the salts and gaseous matters and to leave the manure a heap of matter little better than chaff.

Great discoveries are making daily in this important branch of agriculture. The chemists of Germany have discovered that the seed of plants may alone be manured by which as heavy crops will be produced, as though the *soil* was manured. If this discovery should prove practicable it will in truth result in the greatest benefit which could be conferred upon the agricultural world, both for economy in the preparation of the manure, as well as the application of it to the soil. The mode of its application is to make a liquid and steep the seed in it.

These experiments in Germany have induced similar ones in the United States. Dr. Webster, of New Hampshire, has tried the effect of soaking corn in the common sal-ammonia (hartshorn.) of the druggists, and the result was surprising. The solution was prepared at the rate of four and a half bushels of corn to one pound of ammonia dissolved in water and soaked for five hours—corn from the same ear was planted, soaked and unsoaked, in hills side by side, and the following was the result: No. 1, was planted in good light soil into which a fair dressing of stable manure had been plowed—5 kernels planted in each hill; results the soaked corn produced 8 ears, the unsoaked corn only 4 ears. No. 2, soaked hill gave 5 ears, the unsoaked 3 ears; six hills were tried with corresponding results, and as each hill was treated similarly the fair conclusion is, that the result is to be attributed to the ammonia. The cost of this per pound is only 50 cents; and one pound will be sufficient to manure an entire crop. Let our farmers try the experiment next year!

A chemical preparation is now vending in the Northern States, Hauterive's chemical solution for the benefit of wheat and other seeds, and is said to improve the crops very much, by those who have tried it.

Mr. Campbell, of Scotland, has published the results of experiments which he has made, and the process he has pursued, which present altogether extraordinary facts. He says, "I steeped the seeds of the various specimens exhibited, in sulphate, nitrate, and muriate of ammonia; in nitrate of soda and potash, and in combinations of these,

and in all cases the results were highly favorable. For example, seeds of wheat, steeped in sulphate of ammonia on 5th of July, had by 10th August, tillered into nine, ten and eleven stems of nearly equal vigor, while seeds of the same sample *unprepared*, and sown at the same time, in the same soil, had not tillered into more than two, three and four stems. I prepared the various mixtures from the above specified salts, exactly neutralized, and then added from 50 to 94 hours at a temperature of 60 degrees. I found that barley does not succeed so well, if steeped beyond 60 hours. The very superior specimen of tall oats averaging 160 grains on each stem, and eight available stems from each seed, were prepared from sulphate of ammonia. The specimen of barley was prepared from nitrate of ammonia, it had ten available stems, and each stem had an average of thirty-four grains. The second most prolific specimen of oats was from muriate of ammonia, and the other specimens, strong, numerous in stems, (some having not less than fifty-two,) were from nitrate of soda and potash, and those not so tall from the sulphate or muriate of ammonia. To avoid the difficulty of the grain being too high, a combination of sulphates of ammonia and soda, or potash, should be used."

Speaking of another experiment he had tried, he says, "I found that plants from prepared seeds excelled, in a very marked degree, those from seed sown along side, but not prepared. The former had from five to eight stems, while the latter but two and three from each seed."

These experiments, thus vouched for by very good authority, are well worthy of being tried by our farmers, and should they prove practicable, will be of immense advantage to the agricultural world.

It is a fact long known to the farming community that seeds soaked in water alone, and rolled in plaster of paris, are much benefitted, because it is an absorber and retainer of ammonia, "husbanding the gaseous bodies in the immediate neighborhood of the plants, and thereby serving the purpose of a reservoir to contain and dole out their active nutritive properties, to the roots, as their necessities may require." Powdered charcoal would doubless answer the same ends.

Another subject of deep solicitude to our farmers, should be the improvement of their seeds. It requires as much labor to plant and cultivate a stalk producing but one ear, as it does to rear a stalk which will produce three ears of corn, and the same labor and capital must be employed to produce a crop of wheat, rye, barley, oats, or peas, half ruined by blast and decay, that is requisite to rear one, which is free from all these defects. If the principle be true, 'that like produces like,' from imperfectly matured seed, or from defective seed we need not expect a vigorous and prolific production. We might as well look for a superior race of cattle, from an inferior stock, as to hope for good crops from inferior seed. Let the seed be selected in the field rather than in the grainary. Select seed-corn from those stalks having the greatest number of ears—take the ear which comes first and thereby an earlier and more prolific variety is obtained. Select seed-wheat, rye, oats, &c., from those bunches having the greatest number of shoots—take from these the largest ears, and from these the heaviest grains—sow them, and in a few years an improved variety is obtained, and in this way it will be preserved. By selecting the first cotton-bolls which open and planting their seed, an earlier variety will be obtained. This attention to seed is a matter of economy; for by it the greatest possible product is afforded to labor.

Another subject of interest to the farmer is the improvement of his cattle and swine, his horses and mules, and of the various implements which he employs in agriculture. In the use of tools the great objects to be attained are, the combination of such principles as will enable the farmer to perform the greatest quantity of labor with the least fatigue to his laborers. In the use of agricultural machines labor is not only saved, but the farmer is enabled to develope the various uses to which his products may be applied, and he is also enabled to economise in their use. Such is the corn-cob crusher, by which the farmer is enabled to convert to valuable purposes in feeding his cattle, the cob which has hitherto been regarded as valuable alone for fuel. An improved state of our agriculture will disclose the propriety and value of the introduction of all the improvements in agricultural instruments among us, which are now enjoyed and used by our more economical brethren of the Northern and Middle States. We must hope for improvement, only as we diffuse a taste for agriculture among the people. This must be a work of patience and labor. Our schools can do much—our colleges and higher schools can and should do a great deal in giving direction to the minds of the young men of our country, in this important particular. Instruction should be given in agricultural chemistry—in the practical analysis of soils, the composition of manures, &c. The young men should be educated for farmers as well as for lawyers and doctors. The learned professions are overflowing, and with them, in a pecuniary point of view, it is a "beggarly account" of famished clients and pennyless patients. But make it a part of every one's collegiate course to study the application of science to agriculture, and a taste for the pursuit will be created and extended, and society will reap the benefits of it.

Another subject of no less importance, perhaps of equal importance, consists in diversifying our pursuits. Experience has told us, and every other civilized people, that we cannot acquire a continuing prosperity without this. The policy of the South for the last forty years, has been *to make cotton with which to buy negroes, and to buy negroes to make cotton.* While we have made ourselves dependent on the labor of others for our bread-stuffs in part—our meat in a greater degree, and for our horses and mules in a much greater degree, we have been the insurers against rain and drought, against high and low prices, and now we are paying dearly for the risks assumed. We have relied upon our cotton to furnish us all the necessaries of life, instead of providing them at home, and placing our surplus labor beyond their production, to the production of cotton. We have now but one relief left, and that is, to adopt the rule, which we should have established at the outset. The resources of our State are great, and the over production of cotton should prompt us, that so far as their developement was necessary, our labor should be diverted from its production.

Let the meat necessary for our own consumption be furnished by our own farmers—let the horses and mules required, be supplied by them—let them extend their wheat crops, and not only furnish the demand of flour for our own consumption, but produce it for exportation. We shall become eventually formidable competitors in the flour trade, Southern is intrinsically more valuable than the Northern; it is *drier*, and a given quantity will make more bread than Northern flour. It is for this reason more valuable for the West India trade. It is as certain a crop here as at the North; if sown in good land it yields profitably; in fact, with proper attention our wheat will yield as much to the acre, and it will weigh as much to the bushel as any other wheat. If true to our own interests, Georgia will not only become a *producer* to the limits of her wants, but will become a heavy *exporter* to other markets. In 1842 I had an opportunity of comparing Georgia wheat, with that of each State in the Union. By the request of the Commissioner of Patents, specimens of the different cereal grains were carried to Washington City, by the members of Congress, and at that office were exposed to public inspection. I carried on several parcels, and among them one of the "little white," grown by Jeremiah Clark in this county; it was compared with the other parcels and pronounced by competent judges, to be equal to the best there exhibited. An examination of the specimens collected there satisfied me that Georgia was as capable of producing superior wheat as any other State.

Wool is another article of general and extensive consumption, in the production of which we might profitably participate. We consume, annually, millions of pounds in negro blankets, clothing, hats and other clothes. It is grown mostly in New York and Vermont. Why should not we raise for sale an amount at least equal to that we consume? We can raise as good an article as that we buy, and at much less cost, at less risk, and consequently at greater profit. At the North they are compelled to feed their sheep at least six months of the year; we need not feed them three. We have extensive woods and fields for sheep walks, and every facility for prosecuting the business is enjoyed by us. Why should we not then engage in the pursuit, at least so far as to produce for market as much of the raw material as we consume?

We consume, annually, millions of dollars in shoes, leather, and saddlery of all kinds, and we buy all these from abroad. There is *profit* in this pursuit, and why not appropriate it to ourselves? Our coarse negro shoes are made abroad, and so are most of those which we wear; and nearly all our leather is from abroad likewise. The raw hide is frequently taken from the Georgia farmer, carried abroad, manufactured abroad, and then again sold to those from whom it was purchased. It has happened within a few years past, that raw hides have been purchased in our own county, hauled to Virginia, converted into leather and shoes, and sold again in our State. Now who pays the price of hauling to Virginia, the price of manufacturing the raw article, the price of bringing it back, and the profits upon each operation? It is the people who are simple enough to rely upon others for the supply of their commonest necessaries, and those are the people of Georgia. An idea is prevalent that good leather cannot be made in Georgia; *this has been shown to be a great error;* there is now manufactured at the Penitentiary, from *Georgia hides*, with *Georgia bark*, and in a *Georgia climate*, leather of all descriptions as good as that we buy from the *North*.

Again: the iron we consume all comes from abroad, while our mountains are filled with the richest ores—land cheap and water power abundant. The cost of manufacturing here will prove from thirty to forty per cent *cheaper* than in Maryland or Pennsylvania. All we need is experience, and why will not this be *bought* by those who have the capital to invest—a capital now almost unprofitably invested in cotton making? It is humiliating to reflect, that for every nail in our houses, we are indebted to the skill and enterprise and labor of others from abroad.

And again: the very lime with which we point our chimnies or wash our houses, is dug out from the earth, and prepared by the labor of others 1000 miles distant from us, while here in Georgia we have inexhaustible beds of the rock untouched. And why? Because we do not actually possess energy and zeal enough to burn a bushel of the stone properly, and prepare it for market.

We destroy the article in its preparation, because we are too negligent and indifferent to do it in a suitable manner. And yet what a profitable investment of labor would it be, were our own citizens to determine to supply our own State with the single article of lime, instead of sending annually thousands of dollars to Maine and Massachusetts to procure it, and thereby to reward *their* labor and develope *their* resources, instead of *our own!*

Who does not see in every shop, in every village, and at every cross road, fruits brought from New England for sale? And yet our mountain regions produce them, as finely flavored and as rich as any from abroad. Why will not our people turn their attention to this pursuit, and divert their labor somewhat from the culture of cotton? Fruit, apples especially, is becoming a heavy trade with England, and they not only command a higher price there than their own, but are decidedly superior in quality. The United States produces the finest in the world, and upper Georgia is behind no part of the Union. Will not our mountain friends arouse from *their* lethargy, and not only supply Georgia with the fruit for her consumption, but make her an exporter of it?

The labor necessary for the production of these, if withdrawn from the cultivation of cotton, would not only serve materially to affect the production, but it would find a more profitable investment elsewhere. It would make us independent—would give encouragement and business to our own mechanics, *and all the profit to labor* would remain among us in the shape of increased capital, building up our own people, and enriching our own State, instead of drawing from it its wealth, and adding to that of other States.

We expend large sums annually for the article of sugar. Can we not supply this within ourselves? Every farmer in this county may manufacture from the corn-stalk a sufficiency for each year's support. A little experience is alone necessary to make it as valuable an article as that we buy. Besides, the lower part of our State would yield us enough for the support of the whole State, manufactured from the cane itself. The great difficulty with them hitherto has been that the syrup would not granulate. That difficulty has now been obviated by the recent improvements in sugar making. And even in this latitude, I doubt

very much if with that improved process, the cane would not be found to have ripened sufficiently to make sugar.

In the lower part of our State, the cultivation of the olive would prove a profitable investment of labor. The value of its oil is well known, and though we do not need its fruit for bread, as other nations do, yet we might find a handsome return or our labor in its cultivation.

Let our labor be directed to these several pursuits, and I apprehend the continued cry of hard times will be successfully silenced. With pursuits diversified, the temporary failure of one may be relieved by the prosperity of another; but with one pursuit alone, the failure of that is the prostration of the whole people. May we not hope that our next Legislature may take some steps to develope the resources of our people—to advise them how they can employ their labor to the best account—and to open the way to the improvement and advancement of our agriculture?

And now, how shall we accomplish the objects we have avowed? We feel the country to be depressed by the causes which are here presented, and the effort at relief has commendably been made. Those who have stepped forward in the cause must never look back—but yet the task to arouse the public mind and to give it proper direction, is an Herculean one. But I say, *we must not falter*.

We must ask our country friends to meet with us, and with us to investigate the causes, and with us to apply the remedies. If they will not, however, come to us, we must go to them. Print and circulate among the people the information necessary to arouse them to a proper appreciation of the condition of the country. Get the people to *read*, to *reflect*, and then they *will act*. This society has undertaken the work of reform in this county, and they must not falter in the effort. It may be a source of some expense to give to the people the necessary information which will disclose to them the difficulties about them, and the means of escape, yet the press is the mighty light, which must guide them in the path, and we *must* employ it. The result of a systematic, vigorous, and united effort, will secure to the country lasting and abiding blessings. Our object is not simply to meet and *talk* and *talk*; but it is to meet to talk and to *act*—to stimulate each other, and TO AROUSE THE WHOLE COMMUNITY TO A VIGOROUS EFFORT TO ENRICH THEIR LANDS AND IMPROVE THEIR AGRICULTURE.

Agricultural Societies.

From the North Carolina Watchman.

Our attention has been called of late to the reports and doings of Agricultural Societies in different parts of the country. South Carolina, our sister State, shows a good spirit on the subject. She has a number of Agricultural Societies within her bounds which, by their enterprising and energetic labors, bid fair towards bringing about a sound, practical, as well as theoretical knowledge of Agriculture among our people. Agriculture is the greatest, the most interesting and delightful pusuit of man; and yet we venture to say that it is the least understood of all; particularly in the South. Farmers, generally speaking, have an aversion to what they call "book farming," and consequently prefer plodding through life in the old beaten track—the track of their fathers, and fathers' fathers. The consequence is, that in a few years after opening a plantation, it is worn out. They are driven to the necessity (as they think) of clearing more land—the old fields no longer producing crops worth the labor to till them: they are "turned out," and in a year or two the rains wash great gaping gullies through them, and to the present owner the land is lost. This system is kept up for a few years, and the farmer becomes dissatisfied with the gloomy prospect presented him, of young pines and sassafras growing all around him, and of the young chasms gaping wherever he looks as if waiting to swallow him. He resolves to sell his old homestead. He can never do that part by his family that he should do, if he remains there. So he advertises: "Having determined on removing to the *West*, the subscriber offers for sale his *valuable* plantation, lying on the waters of Panther Creek," &c. &c. This plantation, once valuable indeed, is sold at a price falling one, two, three, or four thousand dollars below first cost; and its late possessor leaves it, perhaps with less means at his command than when he first entered it. This is one system of Agriculture, and a very destructive and shameful system it is; *nevertheless*, it is a very *common* one in many parts of our country.

The purchaser of these worn-out fields and frightful gullies, happens to be a different sort of man: he is a firm believer in book-farming, if you please; for every spare moment from his out-door labor is spent in reading Agricultural books and periodicals; and he watches with the avidity of a beast of prey every experiment that is made, or making, calculated to make some new developement in the science of agriculture. Agriculture is a Science with this man—one that is pleasing and delightful—and not drudgery, a galling yoke, as some men regard it, to which they reluctantly submit, to obtain leave to live.

Six or seven years rolling by, and our scientific farmer, still laboring on the old homestead, has become the pride and boast of the neighborhood. The people just around him thought he was a silly, shallow-brained fellow, at first, else he would never bought such a place to settle on; and they would frequently indulge in very hearty laughs at his expense, when he chanced to speak of his plans. But now, things have taken a change; instead of laughing when they meet with him, their eyes, ears and mouths are all open to catch every word he utters; and when they visit his farm, with all the curiosity of *green ones*, they go to examining this thing and that about the premises. In fine, they are utterly astonished to see what a wonderful change has been wrought upon the old fields: The gullies have all been stopped, and the red clay declivities through which they ran now bear a luxuriant crop of corn. The old fields, late the haunt of wild turkies, lost sheep and hogs and strayed cattle, under the hands of this new, scientific farmer, have shed their pine, sassafras and persimmon bushes, and now bear upon their bosoms rich, waving wheat, barley, rye and oats, or else delight the eye with the deep green of a heavy clover carpet.

This is no fiction—no fancy sketch. The farmers of Pennsylvania, New York and other Northern States, present a more striking contrast with those of North Carolina than the foregoing, or any one would imagine, who has not seen them. The reason why it is so, is very evident: The farmers of those States are a reading, reasoning, and consequently enlightened people—enlightened particularly on the pursuit or occupation of their lives. They not only labor in the fields with their hands but also with their heads. From books they learn the constituent qualities of all the various products of the farm; and from them also learn the nature of the soil they have to work, as well as the kinds of manures suitable to those soils and necessary to facilitate the growth and increase the product of each and every crop they wish to grow.

Let no man despise "book farming," but on the contrary, let every one embrace all opportunities to store his mind with many useful and valuable maxims and hints as well as the philosophy of that pursuit which is the greatness, wealth and happiness of his country. To do this successfully, we know no better plan than to get up Agricultural Societies. By these, enterprising spirit is aroused, which leads men to read, to think and to act, and thus prejudice yields to the light of reason, and wisdom manifests itself on every acre of the farm. We therefore rejoice to see that South Carolina and Georgia are waking up to the importance of a change in their system, who by their Agricultural Associations are destined to exercise a powerful influence upon the prosperity of their people, and glory of themselves.

Several horses died recently in Princeton, N. J., from the effects of eating musty oats.

Agricultural Meetings.

Agricultural Association of Georgia.

MILLEDGEVILLE, Nov. 10, 1845.

The Agricultural Association of Georgia met this afternoon at 3 o'clock. The President being unavoidably absent, on motion of B. S. Jordan, President of the Baldwin County Agricultural Society, Richard S. Hardwick, President of the Hancock County Agricultural Society, was called to the Chair.

The Constitution, as adopted by the Association at its first meeting, held in April last, together with all the proceedings of the meeting on that occasion, were read.

The President then requested the delegates present to report themselves to the Secretary, when it appeared that the following Societies were represented as follows:

Hancock County Agricultural Society.—R. S. Hardwick, A. E. W. Brown, Wm. Terrell, I. P. Whitehead, N. C. Sayre, E. H. Baxter, W. H. Brantley, D. W. Lewis, T. Vinson, R. P. Sasnett, and B. T. Harris.

Putnam County Agricultural Society.—S. Pearson, E. Callaway, O. S. Crediller, Wm. Turner, and Thomas G. Sanford.

Burke County Agricultural Society.—James Grubbs, John T. Brown, J. W. Jones, M. J. Reynolds, and Wright Murphree.

Burke Co. Central Society.—Mulford Marsh.

Oglethorpe Agricultural Society, (Bowling Green)—Wm. Lumpkin, and F. Phinizy.

Baldwin County Agricultural Society.—B. S. Jordan, Thomas F. Green, James Dickson, R. M. Orme, Benjamin A. White, S. K. Talmage, H. V. Johnson, W. H. Mitchell, R. H. Ramsey.

On motion of Mr. Sasnett, it was

Resolved, That an Executive Committee be appointed by the Chair, in accordance with the provisions of the Constitution. The Committee named were—R. P. Sasnett, B. S. Jordan, Thos. F. Green, R. M. Orme, and B. T. Bethune.

On motion of Dr. T. F. Green, the Association then adjourned until half past seven o'clock this evening.

Half past 7 o'clock, P. M.

Association met pursuant to adjournment.

Governor Crawford, President of the Association, being in attendance, took the Chair.

On motion of Judge Sayre, an invitation was extended to any gentlemen present representing Agricultural Societies, whose names have not been previously enrolled, to come forward, furnish their names to the Secretary and take their seats as members of this Association. Whereupon the following gentlemen presented themselves:

Warren Agricultural Society.—John Harris, President.

Clark Agricultural Society.—Wm. L. Mitchell.

Chatham Agr'al. Society.—Wm. P. Bowen.

Walton Agricultural Society.—William Rutherford, President, and James Jackson.

Jefferson Agricultural Society.—J. B. Todd.

The President then called for the reports of the Committees appointed by him, under a resolution of the Association at its organization in April last, when the following reports were presented and read:

Report on the Agriculture of Georgia, by Wm. Turner, Chairman.

Report on Grains, by R. S. Hardwick, Ch'm.
" Stock, by Wm. Terrell, "
" Manures, by J. W. Moody, "
" " by I. P. Whitehead, one of Committee.

All of which were referred to the Executive Committee.

On motion of Judge Sayre—

Resolved, That the Executive Committee cause so much, and such parts of the reports of the several committees and of the proceedings of the Association, as they may deem expedient, to be furnished to the publishers of the "Southern Cultivator" and other gazettes that may be willing to receive them, for publication.

The following preamble and resolution were introduced by Mr. Sasnett:

Whereas, in the opinion of this society, Agriculture is the paramount business of the State; that upon its resources and improvements, all other classes and interests mainly depend for subsistence and for wealth; and that upon the virtue, intelligence and skill of those who direct its labors, comprising as they do the mass of our population, must materially depend our moral and intellectual character as a people.

That it is consequently of primary importance to the merchant, mechanic, manufacturer, and to all other members of society, that this great branch of industry should be especially honored and encouraged, and that the Agriculturist himself should receive all those mutual aids, and that stimulus to industry which are calculated to make him more prosperous in his business, and more useful to society.

That the exhausted and worn out state of much of our lands, the low price of our great staple production, and the great scarcity and high price of bread stuffs and other provisions, particularly admonishes to put forth all our efforts to enlighten its labors and increase its productions.

That to the Legislature of the State as the legally constituted guardians of the public welfare, especially belongs the duty of fostering this great source of our wealth and happiness.

That from the experience of the past, at home and abroad, this association is confident that the patronage of the Government may be advantageously extended, (and without detriment to the financial operations of the treasury) to this great object.

Resolved therefore, That a committee of five be appointed by the Chair, to wait upon and petition the Legislature to lend its aid in promoting and improving this branch of industry in which the State is so universally interested, by the appropriation of such a sum, and under such restrictions and conditions as may, in their wisdom, seem most advisable.

Which were, on motion, adopted.

The President requested to be allowed until to-morrow to make the appointment of said Committee.

The Association then adjourned until 9 o'clock to-morrow morning.

—

Tuesday, Nov. 11th, 9 o'clock, A. M.

Association met pursuant to adjournment.

The President having taken the Chair, presented the following as the Committee appointed under the preamble and resolutions of Mr. Sasnett, adopted last evening: Messrs. Sasnett, B. S. Jordan, Harris of Warren, Todd, R. M. Orme.

Mr. Sasnett, from the Executive Committee, to whom were referred the communications received during the recess by the Corresponding Secretary, reported that they have examined those papers, and find them to contain information of the organization of auxiliary societies in different parts of the State, to the number of fifteen, (including those represented in this meeting,) with lists of members, and expressions of desire to co-operate heartily with this association.

The committee recommend that those communications be preserved, and record made of the names of societies and their members by the Recording Secretary of this association.

On motion of Mr. Hardwick,

Resolved, That the President appoint Committees of three to report at the next annual meeting on the following subjects:

1st. The best method to prevent the washing of hilly land by the frequent heavy falls of rain.

2d. The practicability of reducing to a profitable state of cultivation, the wet lands on the margins of our creeks and branches, and the best method of ditching the same.

3d. The best method of preparing land for the planting and cultivation of Indian Corn.

4th. The best method of preparing land for planting cotton, and method of culture, with suggestions as to the practicability of reducing the number of acres, and attaining an equal result as from a greater number.

5th. The best method of preparing the land for wheat, oats and barley—the method of sowing the same, and the variety most likely to succeed in this climate.

6th. The practicability and importance to the State of growing our own bread stuffs, raising our own horses, mules and pork, and whether the wealth of the State would not be augmented by pursuing such a course and cultivating less Cotton.

On motion of Mr. Hardwick,

Resolved, That the President, Executive committee, and Recording Secretary procure the services of some gentleman to deliver an address on Agriculture, at the next annual meeting of this association.

On motion of Mr. Turner,

Resolved, That the Constitution be so amended as to require the annual meetings of this Association to be held on the third instead of the second Monday in November.

On motion of Mr. Lewis,

Resolved, That the President and Executive Committee be authorised to appoint the next annual meeting of this Association to be held in Milledgeville, or any other place in the State, which in their discretion they may deem proper.

There being no other business, the Association adjourned to meet on the third Monday in November, 1846. BENJ. T. BETHUNE,
Recording Secretary.

Annual Fair of the Warren County Agricultural Society.

WARRENTON, Nov. 10th, 1845.

MR. EDITOR:—The various executive committees of our Society transmit to you for publication, the following synopsis of the proceedings on the day of our agricultural fair.

The members convened at the Court House on Tuesday, 28th October, ult., where many citizens from this, and the adjoining counties, had met to witness the examination of the various kinds of domestic fabrics and stock, which were examined by the several committees, who made their reports for premiums and honors. The premiums and honors awarded, were as follows, viz:

Horses and Mules.—$5 premium to Thos. Neal, Sr., for his bay horse Wonder, 6 yrs. old; $3 premium to Thos. Neal, Sr., for his brood mare Lucinda; 1st honor to Jas. McCason for his sorrel mare; 2d do. to Green Burson for his black brood mare.

Horse Colts, 3 years old and under.—$3 premium to Vincent Johnson, Jr., for his bay colt, 2 years 6 months old; 1st honor to Jas. McCason for his sorrel horse colt, 7 months old; 2d honor to Jas. Kitchens for his sorrel mare colt 15 months.

Geldings.—$3 premium to Sampson R. Culpepper for his saddle horse.

Mule Colts—$2 premium to Thos. J. Wheeler for his mule colt 6 mos. old; 1st honor to Geo. W. Hardaway for 13½ mos. old; 2d honor to Thomas Jones, Sr., for his 6 mos. old.

Cattle.—$2 premium to G. V. Neal for his male calf 1 yr. old and under; 1st honor to Rev. P. N. Maddux for his male calf 1 yr. old and under.

Swine, best pig six months and under:—$2 premium to Rev. P. N. Maddux, 6 mos. old, weight 108 lbs.

Domestic Fabrics.—$2 premium to Mrs. Mary Jones, L. C., best piece of Jeans, 8 yds.; 1st honor to Miss Rina Hunt, 2d best do. 8 yds.; 2d honor to Miss Celia Barksdale, 3d best do. 8 yds.

Domestic Quilts.—$2 premium to Mrs. Anna Thomas for the best bed quilt; 1st honor to Miss Emily Beall, for 2d best do.; 2d honor to Miss Mary J. Harris for 3d best do.

Counterpanes.—$2 premium to Mrs. Celia Barksdale, for the best counterpane; 1st honor to Mrs. W. Fowler for 2d best do.; 2d honor to Miss Susan W. Jones for 3d best do.

Domestic Woollen Coverlets.—$2 premium to Mrs. Lester for two excellent woollen coverlets.

Butter.—$1 premium to Mrs. Sarah Beall for an excellent lot of butter.

Miscellaneous Articles.—Honor for an excellent fancy foot stool, to Mrs. Anna Thomas; honor for some excellent worsted fancy candle mats, to Mrs. Anna Thomas; honor for a pair of beautiful embroidered cloth shoes (uppers) to Mrs. Martha Barksdale; honor for a beautiful willow basket, by a lady of Morgan; honor for a beautiful pin cushion, by Miss Elizabeth Hubbard; honor for a beautiful open worked collar, by Miss Emily Beall; honor for a beautiful fancy ladies' cap, by Mrs. Ann Hale.

There was no election for officers for the ensuing year. The present officers are:

JOHN HARRIS, President,
G. W. HARDAWAY, 1st Vice-President,
SAMUEL HALL, Sr., 2d do.
JOHN H. ROBERTS, jr., Secretary.

Resolved, That the proceedings of the Fair be published once in the Southern Cultivator, Tri-weekly and Weekly Chronicle and in the Southern Recorder.

The Committee on Domestic Fabrics presents to the ladies the thanks of the Society for thus doing honor to, and gracing the occasion with so many specimens of domestic industry, and also for the countenance and encouragement they gave by their presence and approving smiles, to the laudable enterprise in which we are engaged. We take pleasure in remarking that all the ladies have presented their premiums to the Society, which example will be followed by the gentlemen almost unanimously. We have the promise from the ladies that our next fair shall do honor to old Warren. Our prospects are now brighter than at any time heretofore. Owing to late organization, we offered no premiums for grain.

JOHN H. ROBERTS, jr., Secretary.

Fair of the Planters Club of Hancock.

The Annual Fair of the Planters' Club of Hancock, was held on Friday and Saturday, the 31st of October and 1st of November. The members of the Club were particularly gratified at the fine array of stock and domestic manufactures, but regret the few reports on crops, in consequence of the great drought of the season, competitors deeming their results unworthy of notice. At 11 o'clock on Friday, the Club met at the Court-house—President, M. G. Harris, in the Chair—transacted the ordinary business of the Club—appointed their various committees for awarding premiums, and elected their officers for the next year, viz: R. S. Hardwick, President—A. E. W. Brown, J. P. Whitehead and T. Whaley, Vice Presidents—T. H. Audas, Recording Secretary and Treasurer, and Col. N. C. Sayre, Corresponding Secretary.

At 11 o'clock on Saturday, a procession was formed at the Court-house by the members of the Club and citizens, escorted by the Hancock Troop, marched to the Female Academy, where they found already in attendance, a large concourse of ladies in waiting to cheer them on in their noble enterprise, having the walls of the building literally hung with the most choice specimens—the work of their own hands. The meeting was called to order by the President, and the report of the Committees called for, after the reading of which, an able address was delivered by R. P. Sasnett.

Crops.—The Chairman of the Committee on Crops, I. P. Whitehead, presented the following report: To R. S. Hardwick, a premium of a silver cup for the best acre of upland corn; to William Dickson, junior, a premium of five dollars for the best acre of low ground corn; to B. T. Harris, a silver cup for the best acre of wheat; to E. M. Pendleton, a premium of $5 for the second best acre of wheat; to R. S. Hardwick, a premium of $3 for the third best acre of wheat; to R. S. Sayre, a premium of $3 for the best acre of oats. The gathering of the crop of cotton not having been completed, reports on that article will be made to a subsequent meeting.

Horses.—The Chairman of the Committee on Horses, R. M. Orme, presented a report as follows: To Thomas Neal of Warren, the first

premium of $5 for his thorough bred horse, Wonder; to S. A. Pardee, the second premium of $3 for his very beautiful horse, John De Witt; to J. B. Edwards, the first honor for his horse, Ned Soullard; to M. G. Harris, a premium of $3 for the best three year old filly; to Henry Griggs, a premium of $2 for the best two year old filly; to James M. Cason, a premium of $5 for the best brood mare; to Chas. R. Knowles, a premium of $2 for the second best brood mare; to R. S. Hardwick, the first honor for his young mare, Tranby; to F. D. Gonder, the first honor for the best colt under one year old; to J. M. Cason, the second honor for the second best colt under one year old; to T. Jones, a premium of $3 for the best mule colt.

Cattle.—The Chairman of the Committee on Cattle reported as follows: To Dr. J. S. Whitten, red Durham bull, aged, a premium of $5; to Dimas Ponce, a red bull, aged, a premium of $2; to T. C. Grimes, a red Durham bull, aged, the first honor; to Dr. J. S. Whitten, dun Durham bull, aged, the second honor; to Dr. J. S. Whitten, white Durham bull, the best yearling; to J. B. Ransone, red Durham bull, second class, a premium of $1; to J. R. Ransone, white Durham bull, first honor; to R. S. Hardwick, for his cow, Spot, as the best milker, without regard to blood the first premium, $5; to J. S. Whitten, roan cow, Durham, having regard to blood, $5; to T. C. Grimes, red cow, Durham, second premium, $2; to R. S. Hardwick's cow, Flower, third premium, $2; to R. S. Hardwick, red heifer, best two year old, a premium of $2; to J. B. Ransone, red heifer, second best two year old, a premium of $1; to R. S. Hardwick, roan heifer, first honor. Dr. Whitten and Mr. Grimes exhibited other thorough bred stock, highly creditable to their spirited owners, and which bid fair at some future day to be dangerous competitors. Mr. Hardwick also exhibited some half bloods, which fully sustained his character as a judicious breeder, and clearly shows the benefit to be derived from well selected crosses.

Swine and Sheep.—The Chairman on Swine and Sheep, T. M. Turner, submitted the following report: To C. R. Knowles, for the best boar, the first premium, $5; to R. S. Hardwick, for the second best boar, the second premium, $2; to Wm. H. Sayre, for the best sow, the first premium, $3; to C. R. Knowles, for the second best sow, the second premium $2; to R. S. Hardwick, white sow, first honor; to Wm. H. Sayre, premiums of $5, $3, and $2, for the first, second and third best and heaviest fat pigs between 6 and 12 months old; to B. J. Winn, for the best ram, first premium, $2; to B. J. Winn, for the best ewe, first premium, $2; to B. J. Winn, third, fourth and fifth honors.

Domestic Fabrics.—The Chairman on Domestic Fabrics, reported as follows; to Mrs. Lucy Bonner, for the best piece of black jeans, a premium of $3; to Mrs. Martha McCray, for the second best piece of colored jeans, a premium of $2; to Miss R. Hunt of Warren county, for the third best piece of jeans, a premium of $1; to Mrs. B. T. Harris, for the fourth best piece of jeans, the first honor; to Mrs. Richard Fears, for the fifth best piece of jeans, the second honor; to Miss Judy Ann Fears, for the best hearth rug, a premium of $1 25; to Mrs. E. F. Coleman, for the second best hearth rug, a premium of $1; to Mrs. F. P. Bird, for the handsomest window curtain fringe, a premium of $1; to quilt No. 19, (name not given,) first premium, $3; to Emily Bell of Warren county, the second premium, $2; to M. J. Harris, (quilt No. 40.) the third premium, $1; to Mrs. George W. Bass and Mrs. Lockhart, each a quilt, honors; for a quilt, by a lady unknown to the committee, we would award the highest encomiums for the ingenuity and beauty displayed. To Mrs. Lewis, Mrs. Terrel., Mrs. Thomas, Mrs. Bell and Mrs. Parrish, your committee award, and would be pleased to divide between them premiums set apart for their articles, viz: $3 for the best, and $2 for the second best—but your committee find it impossible to decide upon any difference between them. To Mrs. E. L. B. Hall of Putnam county, for the best piece of cotton diaper, a premium of 50 cents; to Mrs. E. S. Bass, for the best piece of domestic silk and cotton, a premium of $1; to Mrs. Terrell, for the best piece of dimity, a premium of 75 cents; to Miss Frances Soullard, for a beautiful dress trimmed with inserting of her own make, a most beautiful article, a premium of $1; to Miss A. E. Kelly, for the best plaid homespun, a premium of 50 cents; to Miss C. E. Haynes, for a satin cradle quilt, most beautiful, a premium of 50 cents; to Miss H. Binion, for an embroidered black silk apron, a premium of 50 cents; to Mrs. F. P. Bird, for two worked shawls, a premium of 50 cents; to Mrs. F. P. Bird, for a superior article of tallow candles, a premium of 50 cents; to to Mrs. E. M. Thomas, for a beautiful article of refined salt, 50 cents; to Miss Russell, of North Carolina, for an ingenious guard chain, a premium of 25 cents; to Mrs. F. P. Bird, for two silk purses, honors; to Mrs. Terrell, for half a dozen pair of half hose, a premium of $1; to Miss E. L. Alford, for a satin work bag, a fancy basket and lady's pocket handkerchief, a premium of 75 cents; to Miss Margaret McKie, of Augusta, for a pair of mitts, an honor. The committee regret that they could not award a premium for a piece of mixed cotton goods, of superior quality, in consequence of the number of yards; owners name not known. To Gen. B. J. Winn, for two bottles domestic wine, vintage of 1844, a premium of $1; to Miss Emily Bell, of Warren county, for a lady's pocket handkerchief, a lace collar and a pair of embroidered slippers, a premium of $1.50; to Miss Lester, of Warren county, for a handsome carpet bag, a premium of $1; to Miss Melinda Sanford, for a bead bag, of curious device, a premium of 25 cents.

Miscellaneous.—To Mrs. M. A. Lewis, for the best turnips, an honor; to James Thomas for the second best turnips, an honor; to Mrs. E. M. Thomas, for the best article of starch, an honor; to Mrs. A. E. W. Brown, for the second best article of starch, an honor; to Mrs. F. P. Bird, for the best article of butter, a premium of 50 cents; to Mrs. A. E. W. Brown, for the second best article of butter, a premium of 50 cts; to A. E. W. Brown, for a specimen of corn, an honor; to F. D. Gonder, for a specimen of cotton picked by one of Oglesby's Gin, honor; to I. P. Whitehead, for a large specimen of the beet, an honor.

After Mr. Sasnett had addressed the meeting, the club adjourned to half past 2 o'clock, when there was a sale made at public outcry of such things as the ladies wished to dispose of, among which was some superior homespun that brought high prices. The Executive Committee, in closing their report, beg leave to return their thanks to the ladies for the splendid array of domestic articles which their industry and ingenuity furnished, as well as their presence.

R. S. Hardwick,
A. E. W. Brown,
T. H. Audas,
} Executive Committee.

Sparta, Nov. 3, 1845.

Monday, November 3.

Mr. John W. Graves, of Newton county, having arrived with a fine lot of stock too late for the fair, in consequence of having been misinformed as to the day, therefore

Resolved, That James B. Edwards, Samuel A. Pardee and James H. Ransone, be a committee to examine his stock and make such report on their merits as in their judgment they deserve, and that said report accompany the proceedings of the fair.

Whereupon, the Chairman made the following report:

The Committee was highly pleased with the exhibition of an Eclipse mare, and colt by the imported Merman, which, in their judgment, would have been dangerous competitors for the premiums. They could but admire a two year old bay colt by Neel's Archer, dam by Saladin. He has all the requisites to make him a useful horse, combining beauty, power and action. The three jacks, Imported Stallion, Henry Clay and Daniel Webster, your committee consider very fine, and would respectfully recommend them to mule raisers. The four jenneys and colts, and four yearlings, do credit to their spirited owner. To wind up the exhibition, Mr. G. showed a mare mule in foal, and from her appearance, we have no doubt of the fact. The committee regret that Mr. G. did not arrive in time with his stock to compete at the fair for the premiums, which they have no doubt he would have divided. He is entitled to the highest credit for his judicious crosses and selections, and to the thanks of our club for the trouble he has taken to add to the exhibition at our fair.

By order of the Executive Committee.

T. H. Audas, Secretary.

Cobb County Agricultural Fair.

The Society convened in Marietta on Friday morning the 14th inst., and adjourned on Saturday afternoon the 15th inst. The meeting was large and very interesting. Messrs. Thomas H. Kirkpatrick and William Harris, Esqrs., Vice-Presidents, presiding at its opening, assisted subsequently by H. R. Foot, Esq. an associate Vice-President.

The weather was delightful during the whole time, and the scene was enlivened by the smiles of the numbers of Ladies who graced the occasion by their cheering presence.

The forenoon of the first day was spent in the business of the Society---the appointment of committees, &c. &c.

The meeting after dinner, was addressed by the Rev. Thos. F. Scott, who was unexpectedly called out, in the absence of Hon. C. J. M'Donald, the Orator of the occasion, who was detained longer than was anticipated at Milledgeville. Mr. Scott acquitted himself with much credit; and his useful suggestions, so earnestly, and eloquently expressed, and so aptly and forcibly illustrated and enforced, will not pass unimproved by his attentive audience.

On motion of Mr. Scott, a committee were appointed to suggest to the Society the best means of diffusing Agricultural information, &c., to report the next morning, and their report ordered to be published.

On Saturday morning that committee, by its Chairman, submitted the following report, which, on motion of Rev. Isaac W. Waddell was accepted, considered and unanimously adopted:

The Committee appointed to suggest to the Society the best means of diffusing information pertaining to the subjects contemplated in our association, respectfully submit the following suggestions:

1st. We recommend the members of the Society to subscribe for some of the Agricultural periodicals published in our country. Among these we particularly recommend the "Southern Cultivator," edited by James Camak, of Athens, and published by J. W. & W. S. Jones of Augusta: and "The Cultivator," published at Albany, N. Y., by Luther Tucker. These are sterling works of established reputation.

2d. We recommend to the members of the Society who are practically engaged in its objects to note particularly their processes of cultivation, modes of rearing stock, &c., and to report the same, with their various success, to the Society. This we regard as of primary importance in effecting the objects of association.

3d. We recommend the formation of a Circulating library, to be accessible to all members of the Society, under the direction of the Executive Committee. This might comprise all the important Agricultural periodicals, and such books as might be purchased or given from time to time, and would, in few years, constitute a valuable collection.

Thos. F. Scott,
A. J. Hansell,
R. M. Goodman,
} Committee.

The suggestion of the Committee as to the Library, was, by resolution, referred to the Executive Committee who are now making arrangements to carry it out.

The Society proceeded to the election of officers for the ensuing year, when, on counting out the ballots, it appeared that the officers of the present year were unanimously re-elected.

Chas J. McDonald, President; H. R. Foot, Samuel Young, Wm. Harris, James S. Bulloch, Thos. H. Kirkpatrick, Hardy Pace, and James Lemon, Vice-Presidents; William P. Young, Treasurer; and A. J. Hansell, Secretary.

PREMIUMS.

In the afternoon, the several Committees on Premiums awarded the following:

Domestic Manufactures.—Rev. Thos. F. Scott, Chairman on Domestic Manufactures, &c: To Mrs. Hairston for the best piece of Homespun (Jeans,) gentlemen's wear, $5; Mrs. Barber 2d best do., certificate of excellence; Mrs. Barber for the best piece of homespun for ladies' wear, $5; Mrs. Young for the best 10 lbs. butter, $5; Mrs. Hairston 2d do. certificate of excellence; Mrs. Gunby of Cherokee county, a pound of beautiful domestic sewing silk, $5.

Agricultural and Horticultural Products.—Col. John Merritt, Chairman on Agricultural and Horticultural products: To James L. Stokes for the best ¼ acre of sweet potatoes, $2; David Dobbs, for best acre of cotton, $3; John W. Lowry for best acre of upland Indian corn, $5; H. R. Foote, for best 2 acres of peas, $1; Wm F. Groves, for best ¼ acre cabbage, $2; Mrs. E. McDonald, for best and largest 25 beets, $1; Valentine Kolb, for ¼ acre beautiful herd's grass, $3.

Stock.—Wm. Harris, Esq., Chairman on Live Stock: To Wiley Roberts, for best Mule Colt, $5; Aaron S. Smith, for 2d do, cert'c of excel'c; Wm. M. Davis, for best horse colt, $5; H. R. Foote, best Hog under 2 years old, $2; N. M. Calder, for 2d do, $1; H. R. Foote, best Pig, under 1 year old, $3; Thos. B. Daniel, 2d do, $2; H. R. Foote, for the best Calf under 1 year old, $2 50; Benj. Page, for 2d do, certificate of excellence.

Agricultural Implements.—James L. Stokes, Esq, Chairman on Agricultural implements, &c.: To R. M. Goodman, for his imported turning Plow, which they highly recommend, $2; James Lemon, for a turning and subsoil Plow united, invented by himself, and which they also recommend highly, $5.

Miscellaneous.—A. J. Hansell, Chairman of Committee on all articles exhibited not comprised in the published list of premiums: To Miss Kilby, for her beautifully wrought Ottoman covers, $1; Mrs Waddell, for her very handsome mats and Ottoman cover, $1; Mrs. Spier, for her pretty and tastefully embroidered apron, $1; Mrs. Husk, for her beautifully and substantially woven counterpane, $1; Mrs. Morris, do $1; Miss Taylor for her skillful and beautiful paintings, an honor.

The Committee also called the attention of the ladies to the rare style, beauty and comfort of a woollen coverlet, shown by Mr. Leonard Simpson, Sen'r., which has been in use for a full half century, and is yet handsome.

There were exhibited by Messrs. E. Denmead, Wm. Root, and Thos. B. Daniel, a corn-sheller, highly improved cutting knives for oats, hay, &c. which are of the highest utility, and challenged the admiration of all who saw them in operation.

The utmost harmony and good feeling prevailed; and unless we very much misconstrue the signs of the times, the soil of Cobb is destined to a highly improved culture. The Society now numbers more than an hundred members, all of whom manifest much interest. Several of the members, Messrs. Goodman, Roberts, Foote and Lemon, manifested a praiseworthy spirit of liberality in offering individually premiums for wool, woollen blankets, &c., in addition to the Society's premiums, for our next Annual Fair.

A. J. HANSELL, Sec'y C. C. A. S.

Barbour Co. Agricultural Society Fair.

From the Eufaula (Alabama,) Shield

The "Barbour County Agricultural Society" met in this place in the Town Hall, on Wednesday, 5th inst. a large number of ladies and gentlemen in attendance. The President (Col. McDonald) called the meeting to order, and in the absence of the Secretary, Benjamin Gardner was requested to act in that capacity.

The proceedings of the last meeting were read, together with the advertisement of the Executive Committee, offering premiums for the best Stock enumerated therein—and for the best articles of domestic manufactures—after which, the President read an appropriate to the occasion, and eloquent extract from an address delivered by E. C. Baxter, Esq, before the Agricultural Society of Hancock county, Ga., and concluded with some very brief, but interesting observations of his own, upon the subject of Agriculture, and the best means for its improvement. The meeting was also favored with interesting addresses from Col. John L. Hunter, Col. John G. Shorter, and H. N. Crawford, Esq

Being the day appointed for holding the Fair, proposed by the Society, and awarding premiums to the successful competitors, a committee, consisting of John Gill Shorter, Dr. A. P. Crawford, M. Browder, A. McGehee and Dr. Thornton, was appointed to assist the Awarding Committee previously selected, in examining the domestic fabrics then lying on the table, before the meeting for exhibition—which committee forthwith proceeded to the discharge of the duties assigned them—when were exhibited to the Society and citizens present, many very fine specimens of the handiwork and industry of the ladies of Barbour county, conclusively proving that we need be dependent on nothing but our own industry for the comforts and conveniences of life. There were exhibited specimens of fine Counterpanes, Quilts and Comforts, which were worthy of the highest commendation, and between them it was difficult to discriminate. Other specimens, such as Jeans, Negro Cloth, both cotton and woollen, were exhibited, of the finest texture and most durable material, reflecting great credit upon the industry of those who had been engaged in their manufacture. Other materials, for which premiums were not offered, were presented, viz: a fine saddle, made by Mr. Fenn, a workman in this place, and some fine leather tanned by Mr. Cargile, at his yard, in this place, which the committee considered worthy of premiums, and consequently awarded them.

After the exhibition of the above noticed fabrics, the Society adjourned till after dinner, for the purpose of examining the Stock which had been brought for exhibition:

The Society again met, agreeable to adjournment, for the purpose of hearing the report of the Awarding Committee, and electing officers for the ensuing year. The President in the Chair, the Committee then made the following

REPORT:

The committee appointed to award premiums at the Fair this day held, report the following as the result of their labors, but take occasion to remark that, in many instances, it was difficult to discriminate, which rendered the duty imposed upon them, of an exceedingly unpleasant and embarrassing character, (as all deserved the highest praise for their efforts in advancing the best interests of the country,) and the Committee only regret that it was not in their power to award a premium to each one. They, however, have discharged their duty to the best of their judgment, and submit the following as the result of their investigation:

Horses.—The best stallion, Nathaniel Roach, $3.00; 2d best, Wm. T. De Witt, $1.00; best filly, Henry Tolson, $2.00; best colt, Wm. T. De Witt, Southern Cultivator; 2d best colt, Edward Battle, honors; best brood mare, T. Flournoy, $3.00; 2d best brood mare, Philip Causey, honors; best mule colt, E.S.Ott, honors.

Cattle.—Best bull, R. C. Shorter, $3.00; 2d best bull, A. McDonald, Southern Planter; 3d best bull, R. C. Shorter, honors; best milch cow, W. T. De Witt, $3 00; 2d best milch cow, R. C. Shorter, American Agriculturist; 3d best milch cow, R. C. Shorter, Tennessee Agriculturist; best 2 year old heifer, R. C. Shorter, Southern Planter; 2d best two year old heifer, A. McDonald, honors.

Swine.—Best boar, A. McDonald, Southern Cultivator; 2d best boar, Robert Martin, honors; best sow, Robert Martin, Albany Cultivator.

Miscellaneous.—Best plow, G. W. Pournell, Tennessee Agriculturist; 2d best plow, Thos. Gillenwaters, honors; best 10 yards negro cloth, Mrs. M. A. Browder, American Agriculturist; 2d best 10 yards negro cloth, Mrs. Alex. McDonald, honors; best counterpane, Mrs. W. Archer, $1 00; 2d best counterpane, Mrs. R. O. Dale, honors; best jeans, Mrs. M. A. Browder, $1 00; best domestic ginghams, Miss Parke, $1.00; best carpeting, Miss Parke, honors; best cotton negro cloth, Mrs. A. McDonald, $1.00; best quilt, Mrs. J. C. Pope, $2.00; 2d best quilt, Mrs. J. G. Shorter, $1.00; 3d best quilt, Mrs. P. M. Calloway, honors; best hearth rug, Mrs. P. M. Calloway, 50 cents; best saddle, Mr. Fenn, $1 00; best leather, Thomas Cargile, Southern Cultivator.

After the reading of the above Report, the Society proceeded to the election of officers for the ensuing year, which resulted as follows:

Dr. J. M. RAIFORD, President.
M. A. BROWDER, 1st Vice-President.
J. A. CALHOUN, 2d Vice-President.
T. FLOURNOY, Treasurer.
M. M. GLENN, Recording Sec'y.
B. GARDNER, Corresponding Sec'y.

Executive Committee.
A. M SANFORD,
J. DENNARD,
E. E. DUBOSE,
H. TOLSON,
W. S. PAULIN,

After which, the Society adjourned.

BENJ. GARDNER, Secretary pro tem.

From the Transactions of the N. Y. Agricultural Soc'y.

Subsoil Culture.

By John Macdonald—President Washington County Agricultural Society.

The site of Salem, as all will remember who have visited that pretty village, in the eastern extreme of a plain that extends some two miles south and west, with very gentle undulations of surface, and may embrace near 3,000 acres. This plain is surrounded by hills, and constitutes the bottom of a very picturesque, natural basin, that geologists conjecture was once filled with water by Black Creek, from the north, and the Battenkill from the east, and was finally drained through a gap in the hills, by which the "Kill" flows westward to the Hudson.

Not far from the centre of this basin lies my farm—the surface rolling—the more elevated portions, gravel—and the low glades, loam—all resting on clay at different depths—approaching the surface, however, only in the loam. For 30 years prior to 1834, it was occupied by two industrious tenants, who taxed its productive powers to their utmost capacity—sowing wheat while wheat would grow, and then covering it with rye, year after year.

I found the farm so exhausted that it was exceedingly difficult to make grass seed catch without manure—and no wonder—for it did seem as if the gravel soil in some of the easiest tilled, and therefore the most exhausted fields, had been *leached*, and little beside clean sand and gravel left. (The course of husbandry adopted, and by which I enjoy both pleasure and profit of seeing these gravel fields giving fair promise of returning fertility, may, perhaps, be the subject of a future communication.) The *loam too*, seems much impoverished by constant tillage and successive annual cropping—but the mere exhaustion of the soil was not the worst of it; for in the lower glades there was not *sufficient depth of soil* for either grass or grain.

The surface of rich alluvial lands, it is

known, may be so impoverished by constant tillage and severe cropping, as to become comparatively barren, but they may be renovated by giving unusual depth to the furrow and bringing up a portion of soil that has never been robbed of its native fertility.

But in my case this could not be, for the clay or rather the subsoil, composed of clay and sand, in many locations almost impervious to water, and altogether sterile, was found at depths of from four to eight inches from the surface. Here then, were two difficulties—my soil lacked fertility, and it lacked depth. It was not only poor, but there was not enough of it. Its fertility might be restored by manure, but the want of depth was always fatal to the crop, in seasons either of drought or moisture.

The great desideratum, then, was to increase the depth of soil. This could not be done by deep plowing, with the common plow, or by the use of the subsoil plow.

The first of these modes is liable to two objections, both of great practical importance. And 1st. In those fields where the depth of the soil varies from four to eight inches, a furrow ten inches deep and of the common width, would require the power of two yoke of oxen—and any considerable increase in the depth of furrow would employ the addition of a third team. 2d. Under such culture the soil is buried deep and the subsoil brought to the surface, presenting a clay-cold, pale face. The great amount of manure necessary to bring such land to at once—to give it the hue of health, and the vigor of fertility, I could not at all afford; and as illy could I avail the slow natural process of amelioration by the frost and the snow of winter, and the showers and the sunshine of summer. My interest required that I should adopt some plan less expensive than the one, and more expeditious than the other.

I had long thought of the subsoil plow as an implement adapted to my purpose; but not until the past winter did I resolve to test theory by experiment, and give subsoil culture a fair trial, deeply impressed with the belief that it steered clear of those insuperable objections that exist to the other mode, and that it was well adapted to effect my object in the most perfect manner, and at the least possible outlay, both of labor and manure. That impression has been deepened by experience and observation.

At our late cattle show and fair, I exhibited my subsoil plow, and am satisfied, not only from the report of a committee, making gratifying mention of it as a new and valuable implement, and awarding me a premium, but also from the universal curiosity excited by its exhibition, and the equally universal marvel "what it could be for," that it may not be out of place here, briefly to describe it and the manner of its working.

The subsoil plow is perhaps best described as "the common plow without a mold board," and having in lieu of it, a cast iron plate four or five inches wide, fastened to the share, and running back (with its plane at right angles to the plane of the landsides) to the heel of the plow, when it is elevated about four inches, constituting an inclined plane, over which the clods broken up by the share pass, and in their progress are still more broken and displaced. The stilts most convenient are those commonly used with the side-hill plow.

It does its work entirely below the range of the soil plow, and at the bottom of the furrow made by it; and in ordinary culture a common plow is always employed at the same time with the subsoiler.
